Background: The red blood cell distribution width (RDW) is a common parameter for measuring anisocytosis in the study of anemia. Recently it has been regarded as a surrogate marker of inflammation and adverse outcome in several diseases. Acute graft-versus-host disease (GVHD) is a common complication of allogeneic hematopoietic cell transplant (allo-HSCT) which is related to inflammation in the context of damage of the host tissue and the release of inflammatory cytokines. We decided to study the utility of this potential inflammatory marker in the setting of GVHD in the allo-HSCT.

RDW>16	5
RDW<16	8

Aims: RDW values were evaluated at the day of infusion (RDW 0), we choose this point in time to evaluate the tissue injury and inflammation secondary to the conditioning regimen, in order to evaluate if there is a major incidence of GVHD.
Methods: We retrospectively evaluated 103 patients who had underwent allo-HSCT for different indications at our center, with a median follow up of 12.8 months (0-235) at our center. The population consisted of 59 males and 44 females, the median age was 43.7 years. The RDW was collected from the hemogram at the day of the HSCT cell infusion, before it was performed (table 1). The IBM SPSS STADISTICS program was used for all statistical analyses. Differences were considered statistically significant when p<005. The median of RDW values in our study was of 16.4 (11.2-38.5). The areas under the receiver operating characteristic (ROC) curves of RDW were ≤18.4 and >18.4 for the selection of the increased RDW cutoff. We evaluated the association of increased RDW (>18.4) with the development of GHVD. A survival analysis of the association of different levels of increased RDW was performed. A subgroup analysis of the Haploidentical HSCT patients (N=13) was also evaluated.

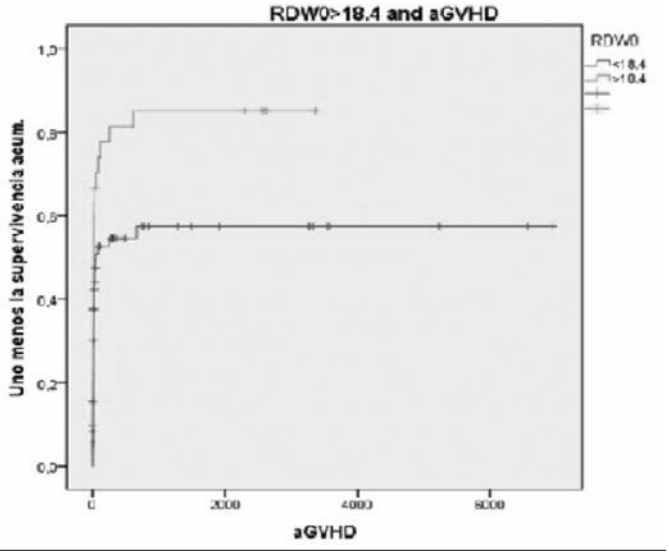

Figure 1.

Results: The presence of increased RDW >18.4 was strongly associated with an increased risk of developing acute GVHD (p=0.009) being present in 80% of the patients. In the haploidentical HSCT subgroup an increased RDW >16 was associated with acute GVHD. (p=0.044). There was no association of chronic GVHD with elevated RDW at day 0 (p=0.563). The survival analysis didn't found an association of high RDW levels with mortality or survival (p=0.301) but a tendency to an increased survival was show between the RDW level subgroups. (figure2). Where a higher RDW seems to have a better survival, but this should be evaluated in a wider sample.
Summary/Conclusions: RDW at day 0 is a feasible predictor factor of Acute GHVD, most likely as a secondary surrogate marker of inflammation secondary to the conditioning regimen. The presence of other factors contributing to the RDW increase (secondary to other comorbidities) cannot be ruled out; but by itself RDW it's an easy and affordable prognosis marker for aGVHD that should be further evaluated.

E1556

COMPARISON OF THE BEEAM CONDITIONING REGIMEN AND THE BEAM CONDITIONING REGIMEN IN THE AUTOLOGOUS TRANSPLANATAION FOR HL AND NHL

S. Lozenov[1,*], P. Ganeva[1], B. Spassov[1], Y. Petrov[1], G. Arnaudov[1], G. Mihaylov[1]
[1]NSHATHD, Sofia, Bulgaria

Background: The BEAM has established itself as a standard of care conditioning regimen in the autologous lymphoma HSCT setting for most transplant centres in Europe. Yet however various other regimens are being compared with it in order to achieved better safety profile, better OS and DFS, in order to improve results with chemoresistant and unfavourable patients. One such regimen is BeEAM (bendamustine, etoposide, cytarabine, melphalan).
Aims: We aimed to compare the efficacy of the BEAM and BeEAM conditioning regimens and to compare there myelotoxicity profile.
Methods: We evaluated retrospectively 114 patients, receiving auto-HSCT at the National Specialized Hospital for Active Treatment of Hematological Diseases in Sofia for relapsed/refractory HL or NHL for the period from 1.01.2013 to 1.07.2016 with a follow-up of patients up to 1.11.2016. 92 of the patients received BEAM and 22 received BeEAM. 2 and 3 year OS and DFS were compared, CR rates and the average time periods to hematological recovery.

Results: The OS at 2 and 3 years respectively was 86.1%, 86.1%, for BeEAM and 78%, 71% for BEAM, the DFS at 3 years was 76.4% in BeEAM and 73.2% BEAM, provided that the differences did not have statistical significance. The CR rate was 63.63% in the BeEAM group *versus* 50% in the BCNU group. 22.72% of the patients receiving BeEAM in SD or in diseases progression achieved CR *versus* 10.86% respectively for the BEAM group. The mean time to hematological recovery for neutrophils was 11.27 days (BeEAM) *versus* 10.24 days (BEAM) and 12.64 days (BeEAM) *versus* 11.12 days (BEAM) for platelets.

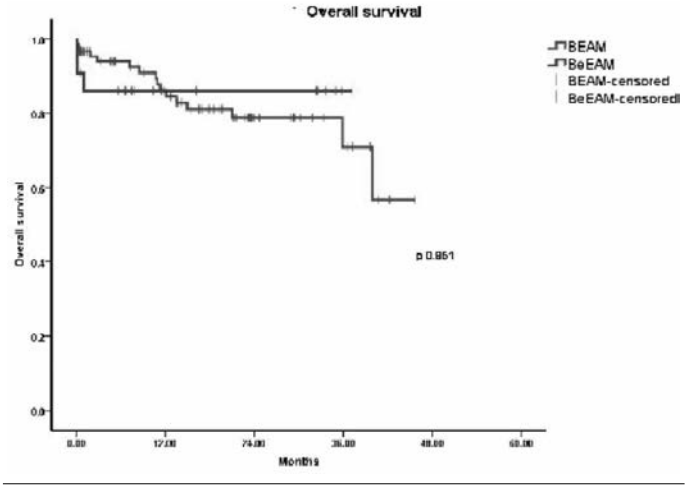

Figure 1.

Summary/Conclusions: BeEAM appears to be a non-inferior alternative conditioning regimen to the standard BEAM, it shows a trend towards higher myelotoxicity, but also a trend towards better short-term results in chemoresistant patients.

E1557

DOUBLE UMBILICAL CORD BLOOD TRANSPLANTATION IN ADULTS: CORRELATION OF ALLELE-LEVEL HLA MATCHING WITH OUTCOME AND WHICH CORD BLOOD UNIT WILL BECOME DOMINANT

M. Westendorp[1,*], D. Hogge[1], K. Song[1], S. Narayanan[1], S. Nantel[1], R. Broady[1], M. Barnett[1], C. Toze[1], A. Gerrie[1], Y. Abou Mourad[1], D. Sanford[1], M. Power[1], D. Forrest[1], S. Heather[1], N. Thomas[1]
[1]Leukemia/BMT Program of BC, Vancouver General Hospital, Vancouver, Canada

Background: Umbilical cord blood (UCB) has been used for alternative donor transplantation for the past 3 decades. Graft failure is not uncommon due to higher degrees of histoincompatibility between recipient and UCB units and fewer hematopoietic precursors in the product. To improve engraftment rates, especially in larger (*i.e.* adult) patients (pts), two UCB units can be used. Double UCB transplantation (DUCBT) is being utilized at many centres although it has been noted that, while both units may contribute to engraftment, only one unit becomes "dominant" – *i.e.* persists to provide long-term hematopoiesis. A variety of predictors of which unit will become dominant have been suggested, primarily the unit that is more closely HLA-matched or the unit with the highest total nucleated cell (TNC) count.
Aims: To determine the likelihood of engraftment, incidence of GVHD, influence of TNC count and HLA mismatch on survival and selection of the dominant cord following DUCBT in adults with high-risk hematologic disorders.
Methods: A retrospective review was performed of adult pts undergoing DUCBT at the referral centre for British Columbia. Recipients signed informed consents for all clinical trials in which they participated. HLA typing at A, B, C and DRB1 loci was done on all pts using high-resolution allele-level testing (HRT). HRT was available at these 8 loci for both UCB units in 25/31 pts; for the remaining units, class I typing was done by serology. UCB units selected had to be ≥4/6 match at A, B (serologically) and DRB1 (by HRT). Combined TNC count for the units had to be ≥30x10^6/kg recipient weight. Conditioning was Fludarabine 40mg/m^2 x4 and TBI 150 cGy x9; GVHD prophylaxis was Tacrolimus/Mycophenolate. Pts received G-CSF 300 mcg s.c. daily from day +1. Outcomes were compared using Fisher's exact test.
Results: Between 06/09 and 09/16, 31 pts underwent DUCBT - 11 males, 20 females with median age 50 years (range 19-59). Diagnosis was acute myeloid leukemia (AML; n=12), acute lymphoid/mixed phenotype leukemia (n=7), chronic lymphoproliferative disease (n=5), MDS (n=4) or other (n=3). All 31 pts recovered ANC>0.5x10^9/L at median of 20 days (range 14-72). Platelet count reached >20x10^9/L in 26/31 pts at median of 38 days (range 24-188). Acute GVHD developed in 26/31 pts (84%) and chronic GVHD in 17 of the 26 pts (65%) that survived to day +100. Seventeen pts (55%) remain alive, in contin-

uous remission at median follow-up of 3 years (range 0.5-7.0). Ten pts (32%) experienced non-relapse mortality from GVHD (5 pts), infection (4 pts) or unknown cause (1 pt). Four pts (13%) have relapsed at 3, 5, 10 and 12 months. Outcomes for pts when the best cord unit match was 0-2 antigen-mismatched (Ag-M/M) were superior (8/12 alive and well) to those pts when the best unit was 3 Ag-M/M (3/9 alive and well; p=0.20). Unexpectedly, 6/9 pts whose best unit was ≥4 Ag-M/M are alive and well. Information on the dominant cord was available on 19 pts (Table 1); in 15/19 pts, the dominant cord was the same or a better HLA match compared to 4/19 with a dominant cord that was an inferior HLA match (p<0.001). However, the TNC was of less importance with the lower TNC unit being dominant as frequently as the higher TNC unit for each HLA match category (Table1).

Table 1.

HLA Match	Higher TNC	Same TNC	Lower TNC
Better n=7 (37%)	3(43%)	1(14%)	3(43%)
Same n=8 (42%)	4(50%)	2(25%)	2(25%)
Worse n=4 (21%)	1(25%)	2(50%)	1(25%)

Summary/Conclusions: DUCBT is effective in adults with life-threatening hematologic disorders. With current UCB inventories, conditioning therapies and supportive care, graft failure is rare - even in adults. HLA disparity between the UCB unit and the patient is a better predictor than the TNC regarding which unit will become dominant. Pts receiving well-matched UCB units (0-2 Ag-M/M) may have better outcomes than pts receiving 3 Ag-M/M units although successful outcomes can be seen even with a high degree (≥4 Ag-M/M) of HLA incompatibility.

E1558

CLINICAL ANALYSIS OF HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR 46 ACTIVE RELAPSED AND REFRACTORY ACUTE PEDIATRIC LEUKEMIA

L. Yuan[1], S. Xue[1], J. Wang[1,*]
[1]Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Given the dismal prognosis for relapsed and refractory (R/R) acute leukemia, many physicians discourage offering hematopoietic stem cell transplantation (HSCT) to adults patients with bone marrow (BM) blasts over 25%. Therapeutic recommendations for pediatric subjects with a similar situation are not available.
Aims: With no significant alternative managing options for these patients, more data are required to make an informed and patient tailored decision.
Methods: We retrospectively analyzed the preliminary outcome of 46 active R/R acute pediatric leukemia including 30 AML and 16 ALL receiving transplantation between 2012 and 2016. Median age at HSCT was 13 years. Active R/R disease was all confirmed by cytogenetics/molecular genetics and aggressive clinical course. Median bone marrow blasts was 46.4% (5-99%). Of note, 27 patients had over 50% blasts in BM. The earliest 13 transplants were conditioned with conventional Bu/Cy or TBI/Cy regimen, thereafter, all received intensified conditioning including FLAG/TBI (N=21), FLAG/Bu/CY (N=2) and CLAG/Bu/Cy (N=10). Immuno-suppressive agents withdrawal started since day 30 if no acute GVHD occurred. Variety of post-HSCT intervention including donor lymphocytes infusion and interleukine-2 injection were performed to reduce relapse. Median follow-up of the whole cohort is 19 months (3–53 months).
Results: Forty-five (97.8%) achieved CR following HSCT. One died of infection before engraftment. All 3 death occurred before 90 day due to relapse. Transplant-related mortality at 1 year was 15.2%. Acute GVHD incidence was 49.3% (grade III 20.4%), chronic 59.5%. Relapse was the major cause of treatment failure and occurred in 28.3% of patients at a median of 1 year post HSCT. Two-year overall survival and leukemia-free survival were 44.8±9.5% and 44.6±8.9%, respectively. Survival of AML patients was superior to those of ALL. Besides, outcomes in patients with primary refractory disease were equivalent to those with relapsed refractory AML which not seen in ALL. Blast percentage 50% in the BM pre-HSCT, TBI based conditioning and chronic GVHD proved to be favorable prognostic features.
Summary/Conclusions: This may validate decision making on if this special group of patients should receive HSCT as salvage treatment.

E1559

POST-TRANSPLANT HIGH-DOSE CYCLOPHOSPHAMIDE AFFECT T-CELL RECONSTITUTION IN BONE MARROW, BUT NOT IN PERIPHERAL BLOOD STEM CELLS RECIPIENTS

E. Mikhaltsova[1,*], M. Drokov[1], J. Davydova[2], L. Kuzmina[1], N. Popova[1], D. Dubnyak[1], V. Vasilyeva[1], O. Koroleva[1], Z. Konova[1], N. Kapranov[2], I. Galtseva[2], E. Parovichnikova[1], V. Savchenko[1]
[1]BMT department, [2]Laboratory of immunophenotyping, National Research Center for Hematology, Moscow, Russian Federation

Background: Hematopoetic stem cell transplantation (HSCT) it the only curative therapy for many patients with hematologic malignancies. Occurrence of complications and mortality after allo HSCT still high and it's strongly associated with immune reconstitution. Despite the wide-spread of Post-Transplant High-Dose Cyclophosphamide (PTCy) immune reconstitution and immunological safety of this method is still poorly understood.
Aims: Evaluated immune reconstitution profile in patients who received HSCT with and without PTCy.
Methods: 62 patients who underwent allogeneic PBSCT in our institution were analyzed in 2 groups; patients with PTCy (n=28) and without PTCy (n=34). The total cohort had 22 males and 40 females, and had median age of 33 years (range 19-61). All patients had hematological malignancy. 21 patients underwent myeloablative conditioning and 41 patients non-myeloalative. In 41 patients received bone marrow transplant. The GVHD prophylaxis consisted of a combinations of ATG-PTCy-CsA-MMF (n=10), ATG-PTCy (n=5), Mono-PTCy (n=1), ATG-CsA-MMF-MTX (n=20), CsA-MTX (n=2), ATG-CsA-MTX (n=2), CsA-MMF-MTX(n=1). In 21 patients received PBSCT. The GVHD prophylaxis consisted of a combinations of ATG-PTCy-CsA-MMF (n=4), ATG-PTCy (n=8), ATG-CsA-MMF-MTX (n=8), ATG-CsA-MTX (n=1). 21 patients had progression disease before transplantation, this could affect the results. Immune reconstitution profile was tested via serial flow cytometry analysis of peripheral blood on day +14, +30, +60 and +90 after allo-HSCT. Anti-CD3 FITC, anti-CD16PE, anti-CD56 PE, anti-CD45 Per-CP-CY^{TM}5.5, anti-CD4 PE-Cy^{TM}7, anti-CD19 APC, anti-CD8 APC-Cy7; anti-CD62L FITC (BD Biosciences, USA); anti-CD14PE, anti-CD16PE, anti-HLA-DR APC (eBiosciences, USA) were used to defined white blood cells subsets.
Results: In a bone marrow recipients the number of CD4$^+$ cells was significantly lower when using PTCy (see Figure 1). On day 14 CD4$^+$ cells count for bone marrow recipients was 42,62±9,99; on day 30 - 114,29±42,36; on day 60 – 140,81±42,53; on day 90 - 126,83±26,12. On day 14 CD4$^+$ cells count for PBSC recipients was 47,47±19,99; on day 30 - 131,49±83,26; on day 60 – 148,08±58,22; on day 90 - 162,93±62,94. At the same time when using the PBSC transplant number of CD4$^+$ cells was not significantly different.

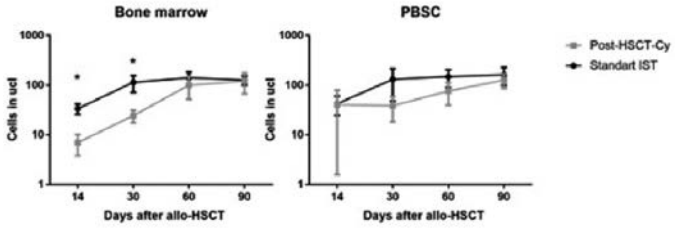

Figure 1. Short-term reconstitution in BM and PBSC recipients with and without Post-HSCT-Cy.

Summary/Conclusions: Lymphocyte recovery was immpared for the PTCy groups in the immediate post-HSCT period but quicly recovered. The mechanism of tolerance induction using PTCy on the + 3, + 4 day not limited to deletion of alloreactive T-cell clones, but also affects other leukocyte subpopulations (B cells, monocytes, granulocytes). The use of PTCy at + 3, + 4 a day is immunologically safe method for prevention of GVHD.

E1560

OUTCOMES OF PATIENTS RELAPSING FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION FOR AML IN FIRST CR: SINGLE CENTER EXPERIENCE

D. Pastore[1,*], P. Carluccio[1], M. Delia[1], A. Ricco[1], A. Russo Rossi[1], M.S. De Candia[1], A. Mestice[1], V. Carluccio[1], V. P. Gagliardi[1], S. D'Agostino[1], C. Pasciolla[1], F. Albano[1], G. Specchia[1]
[1]Hematology with Transplantation-University Policlinico, Bari, Italy

Background: Allogeneic stem-cell transplantation (SCT) is a curative therapy for patients with AML but disease relapse continues to be the most common reason for treatment failure. There is no standard therapy for relapse after SCT and treatment results are very poor. Treatment options range from supportive care through chemotherapy and donor lymphocyte infusion (DLI) up to a second SCT from the same or a different donor.
Aims: We report a retrospective study of 36 patients AML relapsed patients following allogeneic stem cell transplantation in first CR.
Methods: Between 2000 and 2016, 130 adults with AML in first CR underwent allo-SCT. We identified 36/130 patients (27%) who had relapsed and proceeded to review the management and outcomes of these patients; the incidence of relapse was 20% and 54% after myeloablative and reduced intensity conditioning, respectively. The median time to disease relapse after allo-SCT was 11 months (range 5-48); 15/36 (41%) of relapsed patients suffered aGvHD grade II-IV or extensive cGvHD. At time of relapse 15/36 (41%) patients were still taking immunosuppressive treatment, which was immediately suspended.

Results: The patients was subdivided into three groups according to the salvage treatment received palliative /supportive care (PSC group, n=9, 25%), intensive chemotherapy alone(CHT group, n=18, 50%) and chemotherapy with immunotherapy (donor lymphocyte infusion or second SCT)(IT groups, n=9, 25%). Median age at the start of treatment from relapse was 10, 20 and 25 days in the PSC, CHT and IT groups, respectively. In the CHT group, 3 patients (16%) achieved a second CR and 4 (22%) died during reinduction chemotherapy. In the IT group, 6 (66%) pts achieved a second CR after chemotherapy and DLI/second allo-SCT and 3 (34%) died of treatment toxicity. In the whole patients sample, median overall survival (OS) was 7 months (range 2-74), being 4, 5, 13 months in the PSC, CHT and IT group, respectively. Estimated 1-year and 2-years overall survival was 10%, 15%, 40% and 0%, 0%, 12% in the PSC, CHT and IT groups, respectively. In our experience, 3 independent factors for a longer OS after chemotherapy and immunotherapy have be identified: the absence of previous acute o chronic GvHD (HR=2.7,p<0.001), a longer interval between the allo-SCT and relapse than 12 months (HR=1.2, p<0.005) and age less than 40 years (HR=1.3, p<0.005).
Summary/Conclusions: This study shows that salvage chemotherapy (with DLI or second allo-SCT) provides the best results and should be offered, whenever possible, to patients with AML who relapse after allo-SCT performed in first CR. Patients undergoing chemotherapy alone had a poorer outcome. Our results emphasize the need to schedule a prospective protocol combining cytoreductive treatments and immunotherapy in patients with AML relapsing after allo-SCT.

E1561

ALLOGENEIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH CHEMOREFRACTORY HODGKIN LYMPHOMAS: A RETROSPECTIVE MULTICENTER EXPERIENCE OF THE RETE EMATOLOGICA PUGLIESE (REP)

V. Pavone[1,*], F. Gaudio[2], G. Specchia[2], P. Galieni[3], N. Cascavilla[4], P. Mazza[5]
[1]Haematology, Panico Hospital, Tricase, [2]Haematology, Policlinico Hospital, Bari, [3]Hematology, Mazzoni Hospital, Ascoli Piceno, [4]Hematology, "Casa Sollievo della sofferenza" Hospital, San Giovanni Rotondo (FG), [5]Haematology, Moscati Hospital, Taranto, Italy

Background: Second-line salvage high-dose chemotherapy and autologous stem cell transplantation (SCT) have become the standard of care for refractory/relapsed Hodgkin's lymphomas (HL), leading to durable responses in approximately 50% of relapsed patients and a minority of refractory patients. Patients with refractory HL after autologous SCT generally have poor clinical outcomes with available therapies and by far, allogeneic SCT represents the only strategy with a curative potential.
Aims: We examined allogeneic transplantation outcomes patients with HL chemorefractory following last salvage treatment.
Methods: 39 patients with HL who received allogeneic SCT in chemorefractory disease, from 2000 to 2016 were retrospectively studied. The median age was 34 years (range 16-57 years) and 23 (59%) were male. The majority of patients (80%) had had a prior autologous SCT. Most (90%) patients received reduced-intensity conditioning, 59% received matched sibling donor and 41% matched-unrelated donor grafts.
Results: 36 patients survived beyond 100 days and were evaluable for chronic GVHD of whom 22 (61%) remained free of cGVHD and 14 (39%) developed cGVHD. The disease status at day 100 post-transplant was reported in 36 out of 39 evaluable patients. 7 (19%) achieved a CR, 11 (31%) had a PR, 15 (42%) a stable disease and 3 (8%) had progressive disease. Following transplantation 30 (77%) patients have relapsed or progressed at a median time of 12.7 months (range 1- 39 months) post-transplant. With a median follow-up of 28 months (range 3-95 months) 7 patients remain alive in complete remission, 2 are in stable disease and 26 have died. The Kaplan-Meier estimates PFS at five years was 18%. 6 patients (18%) died of non-relapse mortality (NRM) at a median of 300 days (range 28 days- 40 months) following transplantation. The causes of death included infection (n=2), GVHD (n=3), multi-organ failure (n=1).
Summary/Conclusions: Allogeneic SCT could also be a viable option for patients who are refractory to salvage chemotherapy, especially because better results are obtained when this treatment is applied earlier. Despite the reduction of NRM and GVHD, disease relapse still represents the major issue in the setting of allogeneic SCT failure. The availability of novel agents resulting in objective responses may eventually result in increased eligibility for allogeneic SCT.

E1562

RESULTS OF THE IMPLEMENTATION OF CRYOTHERAPY IN PROTOCOLS OF ORAL MUCOSITIS PROPHYLAXIS IN PATIENTS SUBJECT TO A TRASPLANT OF HEMATOPOYETIC PROGENITORS. EXPERIENCE OF ONE CENTER

E. Fernández Poveda[1,*], V. Cabanas-Perianes[1], A. Sánchez-Salinas[1], M. Blanquer-Blanquer[1], M. Berenguer-Piqueras[1], M. Moya-Arna[1], A. Martínez-Marín[1], J.M. Moraleda-Jiménez[1]
[1]Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain

Background: Oral mucositis (OM) is one of the main complication during stem cell trasplantation (HSCT). It has an incidence varies between 47-100%. Numerous prevention strategies have been studied. However, the recommendations of the international guidelines have low evidence to back them up. Cryotherapy is used to reduce OM in conditions that use Melphalan. In our center, we have the cryotherapy implemented in our OM prevention protocol since 2012.
Aims: The main aim is to compare the results in terms of incidence and severity of OM (measured according to World Health Organization scale) in patients in whom cryotherapy was applied and in whom it was not applied as well as the necessity of using morphine and parenteral nutrition. The secondary endpoint is to analyze the occurrence and duration of fever and documentation of infection. Also the length of hospital stay and mortality on day 100.
Methods: We used a cohort of patients with plasma cell dyscrasias who underwent autologous stem-cell transplant with conditioning melphalan 200, Busulfan-Melphalan 140 or melphalan 100 in hemodialysis regimen in which cryotherapy was not applied (2007-2011) and another cohort in which was applied (2014-2016). We did not collect 2012 or 2013 because the measure was being implemented. It consists of administering ice poles to the patient who must chew before, during and after the infusion of melphalan. The t-Studen and Chi square method was used to estimate the rates of incidence and the baseline characteristics. The regression logistic method was used to the multivariant and univaritan analysis. Hazard ratios and 95% were estimated with the use of logistic regression model.
Results: The baselines characteristics can be seen in table 1. All patients in both groups had OM. In the cryotherapy and non-cryotherapy groups, the distribution was respectively: grade I 20% *vs* 16%, grade II 40% *vs* 10.8%, grade III 31.4% *vs* 59.4% and grade IV 8.5% *vs* 13.5%. We observed a reduction in the incidence of severe mucositis (grade III and IV) in the group in which cryotherapy was used against the cohort in which it was not (40% *vs* 72.9%, p=0.005). The need for morphine was also lower in the cryotherapy cohort (54% *vs* 72%, p=0.149). The use of parenteral nutrition was lower in the non-cryotherapy group (8.57% *vs* 13.5%, p=0.7).The prevalence of fever was predominant in the cryotherapy group (51% *vs* 43%, p=0.48), but and infection was documented on more occasions in cryotherapy group (27% *vs* 81%, p=0.04). The median number of days the patients were discharged from the cryotherapy group was lower (+14 *vs* +15 median days, p=0.39) and the mortality at day 100 was higher in the non-cryotherapy group (0% *vs* 8%, p=0.24). Decreased mucositis degree was associated in both univariate and multivariate analysis only with cryotherapy (p= 0.01 and p=0.0003). Hazar ratio was 0.81 (IC 95% 0.06-0.55).

Table 1.

Characteristics	NON-CRYOTHERAPY	CRYOTHERAPY	p
N	37	35	
Gender F/M n (%)	40/60	60/40	0.23
Age Median (Range)	59 (26–70)	57 (38–73)	0.99
Previous lines Median (Range)	2 (1–4)	1 (0 –5)	0.2
Response n (%)			
CR	27	40	
PR	56	14	
VGPR	13	40	
SD/PD	2,7	5,7	
Conditioning n (%)			0.2
MEL200	78	74	
BUMEL140	21	22,8	
MEL100HF	0	2,8	

Summary/Conclusions: In our center, cryotherapy reduces significantly the severity of mucositis. The use of morphine and parenteral nutrition and other complications do not present such a drastic decline, probably because they influence the gastrointestinal mucositis, which is not combatted with cryotherapy. With this results, we are encouraged to continue to include cryotherapy in our protocols.

E1563

REDUCED INCIDENCE OF PRIMARY GRAFT FAILURE IN PATIENTS UNDERGOING HAPLOIDENTICAL STEM CELL TRANSPLANTATION: A SINGLE CENTER EXPERIENCE

A. Martínez-Velandia[1,*], M. Gasior[1], R. de Paz[1], S. Cortez[1], D. Bueno[2], A. Sastre[2], M. Canales[1], A. Pérez-Martínez[2]

[1]Hematology and Hemotherapy, [2]Pediatric Hemato-oncology, Hospital Universitario La Paz, Madrid, Spain

Background: Haploidentical stem cell transplantation (HSCT) is an alternative for patients without HLA matched donors. However, primary graft failure (PGF) and graft *versus* host disease are still limitations derived from alloreactivity due to HLA mismatch. T cell depleting approaches (*in-vivo* with post-transplant cyclophosphamide (PT-Cy) or *ex-vivo* with graft engineering) and surveillance for anti HLA antibodies are strategies intended to reduce these complications. PGF has a high mortality, and treatment with a second graft is not well defined in terms of donor, source, graft engineering or conditioning.
Aims: Our objective is to describe the incidence and risk factors of PGF and treatments if needed.
Methods: We retrospectively analyzed 40 consecutive patients who underwent HSCT from 2014 to 2016: unmanipulated for 20 adults and graft engineering for 20 children (CD34 selection/TCRab depletion, n= 6; and CD34 selection/CD45RA depletion, n=14). The stem cell source was mobilized peripheral blood in all cases. GCSF was sistematically used from day 5 until engraftment. We used descriptive statistical methods for analysis.
Results: Patient characteristics are described in Table 1. Conditioning regimen was Bu-Flu-Cy (n=18, adults), Thio-Bu-Flu (n=2, adults), Flu-Mel-Thio for all pediatric patients. ATG was used in 6 children and TLI in 14 children. All adult patients were given PT-Cy. Only one adult patient had high titer donor specific anti HLA antibodies and was desensitized with plasma exchange, Rituximab and IVIG before transplantation. All patients engrafted before day 28 and no PGF diagnosis was established in our serie. We found that 4 patients (3 children, 1 adult) required a boost of CD34 selected graft from the same donor for secondary GF and poor graft function.

Table 1.

	Adults n=20	Children n=20
Age (years)	50 (22-70)	5 (0-15)
Sex	17 M / 3 F	5 M / 15 F
Diagnosis		
AML	5	6
MDS	3	0
ALL	2	9
Aplastic anemia	0	2
Lymphoma	10	0
Immunodeficiencies	0	3
Conditioning		
Myeloablative	10	0
Reduced intensity	10	20
ATG	0	6
TLI	0	14
PT-Cy	20	0
Graft		
Unmanipulated	20	0
TCRab depleted	0	6
CD45RA depleted	0	14
Cell dose (median)		
CD34 x10^6/Kg	4,4 (2,7-7,5)	6,44 (2,4-9,5)

Summary/Conclusions: PGF incidence described in literature is 5-10%, we did not find any primary graft failure in our serie. Desensitization therapy appeared to be effective in one patient with anti HLA antibodies. All CD34 boosts were performed for secondary graft failure/poor graft function due to treatment toxicities or viral infections. Unfortunately, analysis of causes and risk factors for secondary GF requires a larger number of patients to be determined.

E1564

RESULTS OF HAPLOIDENTIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH LYMPHOMA: A SINGLE CENTER EXPERIENCE

Z. Gulbas[1,*], D. Cekdemir[1,2], I. Dora[1,2], E. Er[1,2]
[1]Bone Marrow Transplantation Department, [2]Anadolu Medical Center, Kocaeli, Turkey

Background: Allogeneic hematopoietic stem-cell transplantation (allo-HSCT) is a potentially curative treatment for a variety of hematologic malignancies and nonmalignant hematologic disorders. However, only about a third of candidates for allo-HSCT have HLA-matched siblings. For patients who lack HLA-matched siblings, partially HLA-mismatched (haploidentical) related donors are good alternative sources of stem cells for allo-HSCT
Aims: In this retrospective, single center study we evaluated safety and efficacy of haploidentical allo-HSCT compared to those of HLA-matched allo-HSCT in patients with lymphoma
Methods: A total of 81 lymphoma patients(Hodgkin and Nonhodgkin) with a mean age of 42 years who underwent allo-HSCT(HLA matched n=46, haploidentic n=35) between July 2010 and July 2016 were analyzed. All patients received Cyclophosphamide (Cy) 50mg/kg i.v. on days +3 and +4. All patients initiated CsA day +5, and then adjusted according to the plasma levels. In addition to CsA, all haploidentical allo-HSCT recipients received MMF until day +35
Results: There were no significant differences in age, sex, diagnosis, disease status up-front HSCT, or transplant characteristics between the groups except a higher median number of stem cells infused in haploidentical group (p=0.004). The median follow-up was 13 months for haploidentical group and 12 months for HLA-matched group. Outcomes of patients are summarized in Table-1
Summary/Conclusions: Our results suggest that haploidentical allo-HSCT is a safe treatment modality in patients with relapsed lymphoma who lack HLA-matched siblings. The major problem are seems to be viral infections. Future challenges remain in improving post-transplant immune reconstitution and finding the best approach to reduce the incidence and severity of viral infections, while preserving graft-versus-lymphoma effect to prevent the recurrence of the underlying disease

E1565

COLLECTION OF PERIPHERAL BLOOD HEMATOPOIETIC PROGENITOR CELLS (PBPC) FROM HEALTHY DONORS: 15 YEARS SINGLE CENTER EXPERIENCE

B. Aguado[1,*], E. Jimenez Barral[1], A. Arriero[1], J. Cornago[1], Y. Paz[1], I. Vicuña[1], V. Gomez[1], R. de la Camara[1], A. Figuera[1], A. Alegre[1]
[1]Hematology, H.U. La Princesa, Madrid, Spain

Background: hematopoietic stem cell transplantation (HCT) is, nowadays, a consolidated therapy within the treatment of multiple hematological pathologies. In the last two decades, the main method of obtaining hematopoietic progenitor cells is blood leukapheresis after mobilization with granulocytic colony growth factors (G-CSF).
Aims: To describe the experience of our center in apheresis of healthy family donors in the last 15 years. Furthermore, analyze the influence of different variables on the procedure and the yields obtained.
Methods: retrospective analysis was performed on 189 hematopoietic progenitor cell collection (HPCC) from January 2002 to December 2016. The study was carried out at Apheresis Unit, Hospital de La Princesa, Madrid, Spain. Progenitor cells mobilization was performed with G-CSF in all cases at a dose of 10mg/kg b.w. Apheresis device was COBE Spectra in all cases and citrate was the anticoagulant used for all the apheresis procedures. All donors were carefully evaluated and informed on the donation procedure and signed an informed consent for apheresis. The venous access used was mostly peripheral venous access in antecubital veins, and in only 7 cases (3.7%) central venous catheter was required. Donor details studied were age, sex, AB0 group, number of apheresis, number of CD34+ per kilogram collected, and processed volume.
Results: among the 189 donors, 85 were females and 104 were males (45% *vs* 55%). The hematologic pathologies that motivated transplantation were, in order of frequency, Acute Myeloid Leukemia (AML) (40.2%), Myelodysplastic Syndrome (MDS) (13.8%), Acute Lymphoblastic Leukemia (ALL) (10.1%), Hodgkin´s Lymphoma (HL) (8.5%), Non-Hodgkin´s Lymphoma (NHL) (6.3%), Multiple Myeloma (MM) (5.3%), Chronic Myeloid Leukemia (CML) (4.2%), others (11.6%). Donors most frequent AB0 group was A and in 123 of all cases (65%) donor and recipient had the same group. Median weight of donors was 74 Kg and in recipients was 70.5 Kg. Median age of our donors was 50 and median age of recipients was 51 years. Twenty donors were >65 years (10.6%) and 10 were>70 years (5.3%). Median of processed volume was 13 liters, but if we stratify that volume by recipient's weight, in those whose were heavier than 100 kg, median of processed volume was 18 liters. Two apheresis procedures were performed only in ten donors. Of these, 2 were older than 70 years (20% of total donors over 70 years of age) compared to 8 under 70 years of age (4.5% of all patients in that age range). The median of CD34 + / kg collected was 5 x 10^6. Among the age ranges, median yield of CD34+/Kg in patients older than 70 years was 3.55 x 10^6, in patients between 31 and 69 years was 4.96 x 10^6 and in patients younger than 30 years was 5.5 x 10^6. The apheresis procedure was mostly well tolerated, with only mild symptoms of hypocalcemia and disturbances related to venous access in a minority of cases. No significant long term adverse effect has been observed in the blood tests reported to our centers during the five years of follow up after the donation.
Summary/Conclusions: donor age and weight discrepancy with recipient were the factors that significantly affected PBPC yields in our experience in healthy donors. These factors had also an impact in the amount of liters of volemia processed, although in most cases only one apheresis procedure was enough. Adverse effects of apheresis for PBPC collection were the same as for other apheresis procedures such as those related to venous access, almost always peripheral one and citrate toxicity.

Stem cell transplantation - Experimental

E1566

ALLORESPONSES OF HUMAN T-CELLS FROM ADULT PERIPHERAL BLOOD AND UMBILICAL CORD BLOOD ARE DIFFERENTIALLY IMPACTED BY LENALIDOMIDE - IMPLICATIONS FOR AHSCT

C. Besley[1,*], E. Kotsiou[1], R. Petty[1], A. Sangaralingam[2], C. Chelala[2], E. Ghazaly[1], R. LeDieu[1], J. Gribben[1], J. Davies[1]
[1]Centre for Haemato-Oncology, [2]Centre for Tumour Biology, Barts Cancer Institute, London, United Kingdom

Background: Immunomodulatory drugs (IMiDs), such as lenalidomide provide a tool to enhance both direct anti-tumor and graft-versus-tumor effects after allogeneic haematopoietic stem-cell transplantation (AHSCT). However, early clinical experience with IMiDs after AHSCT using adult peripheral blood (APB) as a stem cell source has been limited by induction of graft-versus-host disease. Characterization of the mechanisms by which IMiDs can modulate alloresponses of T-cells from different cell sources could facilitate more effective use of these drugs in the setting of AHSCT.
Aims: To use *in vitro* modelling to identify changes in alloresponses of APB and umbilical cord blood (UCB) T-cells after exposure to the widely used IMiD lenalidomide.

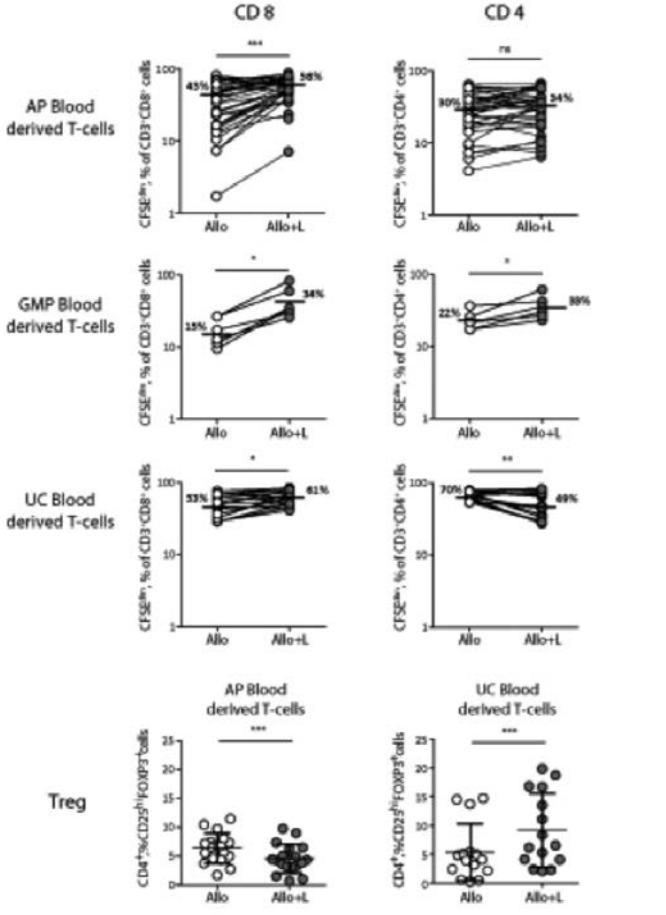

Figure 1.

Methods: We have used multi-parameter flow cytometry and gene expression profiling to perform an in-depth characterisation of the phenotypic and genotypic effects of clinically relevant concentrations of lenalidomide treatment on T-cells during allogeneic co-culture. Using GCSF-mobilised APB (GMPB), steady state APB and UCB PBMC as responder cells in allogeneic co-culture we have been able to compare the differential effect of lenalidomide on these three cell sources. Allogeneic responder cells were labelled with CFSE (carboxyfluorescein diacetate succinimidyl ester) to allow quantification of allo-proliferation. Responder T-cell subsets including naive, memory, activated, cytotoxic and regulatory were interrogated. Functional effects of lenalidomide treatment including cellular capacity to produce cytokines, degranulate and exert direct cytotoxicity was also assessed. RNA was extracted from highly purified proliferative and non-proliferative $CD8^+$ T-cell fractions following a combination of magnetic and flow-sorting and gene expression changes assessed by Affymetrix whole genome array and qRT-PCR.

Results: We demonstrate that lenalidomide increases net alloproliferation of APB T-cells by selectively enhancing allospecific proliferation of $CD8^+$T-cells. These $CD8^+$ T-cells have enhanced effector memory differentiation, are enriched for polyfunctional effectors, and have a distinct gene expression profile with altered expression of key immunoregulatory genes and pathways. This effect on $CD8^+$T-cell proliferation was seen across all 3 cell sources. Importantly a differential effect on $CD4^+$ T-cell responses was observed depending on cell source. Lenalidomide treatment of APB results in no change in CD4+ T cell proliferation overall, but leads to reduced frequencies of $CD4^+$ regulatory T-cells (Treg). In contrast lenalidomide treatment of GMPB resulted in a significant increase in $CD4^+$ T cell proliferation, with no effect on Treg cell frequencies. Most strikingly, although lenalidomide treatment of UCB T-cells during allostimulation results in a similar increase in alloreactive effector $CD8^+$T-cells, it also reduces allospecific proliferation of $CD4^+$T-cells and selectively expands frequencies of Treg, resulting in a net reduction in UCB T-cell alloproliferation.
Summary/Conclusions: Our findings show that lenalidomide has a qualitatively different impact on alloresponses of T-cells from different cell sources, with a potentially tolerogenic effect on UCB T-cells. These findings have important implications for the future use of IMiDs in the setting of AHSCT.

E1567

USING MARKER GENES ANALYSIS INSTEAD OF MLR ASSAY FOR IDENTIFICATION OF FUNCTIONAL CD4+FOXP3+ REGULATORY T CELLS IN GVHD PROPHYLAXIS

T.-J. Chiou[1,*], H.-H. Lin[1], K.-H. Chien[1], W.-H. Wu[1], J.-Y. Jian[1], S.-T. Chu[2], W.-F. Tzeng[3]
[1]Division of Transfusion Medicine, Department of Medicine, Taipei Veterans General Hospital and National Yang-Ming University School of Medicine, [2]Institute of Biochemical Science, National Taiwan University, Taipei, [3]Department of Life Science, Fu-Jen University, New Taipei City, Taiwan, Republic of China

Background: There are two types of CD4+CD25+FoxP3+ regulatory T cells (Tregs), natural Treg cells (nTreg) developing in thymus, and induced Treg cells (iTreg) arising from CD4+ naïve T cells. The iTreg cells have been considered important for maintenance of immunological tolerance and correlate with the occurrence of GVHD in some studies. Establishing a quick method to identify the functional iTreg cells is worthy of focusing. Five to ten percent Tregs could be found in human CD4+ T cells and should be expanded via *in vitro* cell culture.
Aims: In order to improve the efficiency of Treg cells for the prevention of GVHD, we attempt to establish a relatively quick analytic method to identify the functional iTreg cells, and then to curtail the iTreg cells harvest time for clinical use. Therefore, using qPCR for marker genes analysis instead of MLR (mixed lymphocyte reaction) assay is an important issue.
Methods: Mouse splenocytes were prepared from mouse spleen. Human PBSC were prepared from peripheral blood (PB) of healthy donors by Ficoll-Hypaque density gradient centrifugation. All T cells were isolated by negative selection, then CD4+naïve T cells were harvested. CD4+ naïve T cells were activated with anti-CD3/CD28 beads in the presence of IL-2, TGF-β and retinoic acid (RA) containing RPMI1640 medium. The protocol is showed in Fig. 1.

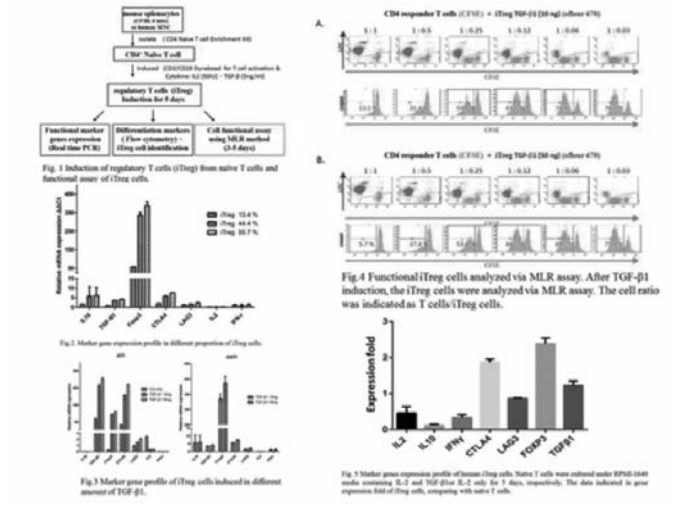

Figure 1.

Results: Seven genes for qPCR analysis were used to identify the functional iTreg cells. We used the different proportions of iTreg cells in total naïve T cells for 7 genes expression analysis and MLR assay to investigate the relationship between gene expression profile and iTreg cell function. The data of marker genes analysis were shown in Fig2. It indicated that the different proportion of iTreg cells could show the different expression profile of these genes. Obviously, the *FoxP3* gene expression increased in a great level. Based on our previous

experiments, iTreg cells induction could be TGF-b1 dependent. After different amount of TGF-b1 induction, the genes expression profile also showed the coincidence of the data in Fig.2 (Fig.3). Using the same iTreg populations, MLR assay have been investigated for 5 days. The T cell suppression percentage would be dependent on the iTreg cells proportion (Fig.4A and B). It indicated that the gene expression levels can represent the biological function of iTreg cells. It's the better way to identify the iTreg cells. Further, we have used PBMNC for Treg cell induction, the marker genes expression analysis also showed in Fig.5. After comparing with IL-2 cultured T cells, the gene expressions revealed the difference in between iTreg cells and un-induced T cells.
Summary/Conclusions: Our study showed that MLR assay should spend 3 to 5 days for identification of the functional iTreg cells, however, the marker genes analysis took only one day for that. Besides, MLR assay is a more complicated method than qPCR analysis. Using simple analysis for human iTreg cells functional identification could save the time for clinical application and might prevent GVHD occurrence effectively.

E1568

OXIDANT-ANTIOXIDANT SYSTEM IN PATIENTS WITH MULTIPLE MYELOMA
L. Aleksanian[1,*], L. Rybakova[1], S. Kapustin[1], S. Gritsaev[2], S. Bessmeltsev[2]
[1]Biochemistry laboratory, [2]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Multiple myeloma (MM) is one of the most widespread malignant B-cell lymphoproliferative disorders and is characterized by a clonal proliferation of atypical plasma cells in bone marrow or, less frequently, in extramedullary locations synthesizing monoclonal immunoglobulins. Currently, autologous hematopoietic stem cell transplantation (auto-HSCT) is recognized as the standard method of treatment for young patients (≤65 years old) with MM. Moreover, the best auto-HSCT results are observed in patients who have received new medication (thalidomide, bortezomib, and lenalidomide) during induction therapy and who have achieved at least a very good partial response, which leads to a significant increase in overall survival. However, studies reflecting the impact of this kind of treatment on the dynamics of oxidant-antioxidant indicators are virtually non-existent. At the same time, the possibility of treating developing diseases by prescribing medication makes the problem highly relevant.
Aims: The aim of the study was to investigate the state of OS-AOS in patients with MM during auto-HSCT.
Methods: We studied 20 patients (11 men and 9 women, mean age 49 years) who followed auto-HSCT after high-dose melphalan. The control group consisted of 50 age- and sex-matched healthy persons. The plasma levels of malonic dialdehyde and cerulloplasmin as well as activities of superoxide dismutase and catalase were measured by standard biochemical techniques. In erythrocytes, the level of non-protein thiol groups was studied. The state of OS-AOS was investigated in each patient four times: before and after conditioning with melphalan, at the moment of maximal leukocyte decrease and after complete reconstitution from cytopenia.
Results: We have found the features of impaired balance in OS-AOS in MM patients before as well as in course of auto-HSCT. The level of malonic dialdehyde in MM patients was not significantly different from that in the control group. At the same time, cerulloplasmin plasma level as well as catalase activity were significantly increased in patient group ($p<0.05$), whereas the level of non-protein thiol groups was decreased in MM ($p<0.05$). The results of our study have shown, that an imbalance of OS-AOS is frequently seen in MM patients and, possibly, could influence the course of auto-HSCT.
Summary/Conclusions: The results of the study indicate a high frequency of occurrence of disturbance of the condition of OS-AOS in patients with MM. The imbalance in the functioning of this system is not entirely eliminated in the process of treating the patients with MM using auto-HSCT. The question of the necessity and methods of the possible correction of OS-AOS in patients with MM, particularly during auto-HSCT, requires further study.

E1569

SURFACE RECEPTOR EXPRESSION PROFILE DEFINES ALLOREACTIVE DONOR CD8+ T-CELLS AFTER MURINE ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION
C. Bäuerlein[1], M. Qureischi[1,*], C. Brede[1], A.-L. Jordán Garrote[1], S.S. Riedel[1], M. Chopra[1], A. Mottok[2], S. Thusek[1], M. Ritz[1], K. Mattenheimer[1], C. Graf[1], H. Einsele[1], P.G. Schlegel[3], R.S. Negrin[4], A. Beilhack[1]
[1]Medical Department II, University Clinics Wuerzburg, Wuerzburg, [2]Würzburg University, Institute of Pathology, [3]University Clinics Würzburg, Department of Pediatrics, Würzburg, Germany, [4]Division of Bone & Marrow Transplantation, Department of Medicine, Stanford University, United States

Background: Acute graft-versus-host disease (aGvHD) is a severe and often life-threatening inflammatory complication of allogeneic hematopoietic cell transplantation (allo-HCT). aGVHD is mediated by alloreactive donor T cells attacking the gastrointestinal tract, liver, and skin of the host. Efficient strategies to improve aGvHD-related morbidity and mortality will rely on more precise methods than preemptive immunosuppression to consistently predict aGvHD and abrogate disease manifestation without exposing patients to an unwarranted risk for infectious complications. Recent insights into the multistep-pathophysiology of aGvHD provide a good basis for the development of new tests to identify individual patients at risk before the onset of aGvHD.
Aims: As pathologic T cell responses rely on spatiotemporally defined programs of T cell activation, acquisition of effector functions, and homing to GvHD target tissues it appeared attractive to assess receptor expression profiles of peripheral blood T cells as potential predictive markers.
Methods: Therefore, we characterized the surface receptor expression profile of peripheral blood donor lymphocytes early after allo-HCT in two independent murine models across minor histocompatibility antigens (miHAg) with multicolor flow cytometry. C57Bl/6 (H-2b, Thy1.1+) or B10.D2 (H-2d, Thy1.1+) T cells plus bone marrow cells were transplanted in conditioned (8Gy) miHAg mismatched BALB/B (H-2b, Thy1.2+) and syngeneic C57Bl/6 (9Gy) or BALB/c (H-2d, Thy1.1+) recipients. To identify suitable predictive markers, we compared the expression pattern of allo-HCT recipients to syngeneic HCT recipients and untreated wild type controls.
Results: Comparing a panel of T cell surface receptors, we found the homing markers α4β7 integrin, and P- and E-selectin ligand highly up-regulated on allogeneic peripheral blood donor $CD8^+$ T cells at peak time points of cell migration. The combination of these homing markers with the activation markers CD25 and CD69 at later time points and low expression levels of L-selectin allowed to define alloreactive donor T cells.
Summary/Conclusions: Based on this data we propose that alloreactive CD8+ T cells can be identified in miHAg allo-HCT recipients upon their homing receptor expression pattern as soon as six to ten days before the onset of aGVHD.

Thalassemias

E1570

SOLUBLE FORM OF TRANSFERRIN RECEPTOR IS ASSOCIATED WITH AGE AT DIAGNOSIS AND RISK OF THERAPEUTICAL INTERVENTION AND IRON OVERLOAD IN PATIENTS WITH NON-TRANSFUSION-DEPENDENT THALASSAEMIA

P. Ricchi[1,*], A. Meloni[2], S. Costantini[1], A. Spasiano[1], T. Di Matola[3], A. Pepe[2], L. Pistoia[2], P. Cinque[1], A. Filosa[1]
[1]AORN A. Cardarelli, Naples, [2]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [3]AORN Monaldi-Cotugno-CTO, Naples, Italy

Background: The soluble transferrin receptor (sTfR), that fully reflects the marrow erythropoietic activity, was found to have not only a striking diagnostic accuracy in predicting the risk of extramedullary haematopoiesis (EMH), but also in scoring disease severity in non-transfusion-dependent thalassemias (NTDT).
Aims: We retrospectively evaluated the relationship between sTfR and some fundamental events in the life and in the management of patients with NTDT.
Methods: We considered 111 NTDT patients with four genetic entities of NTDT: homozygous or compound heterozygous state for β-thalassemia, triplicated α genotype associated with β heterozygosity, deletional HbH, and combination of a β defect plus a β chain variant. sTfR was measured with a *commercially available kit*. A group of patients was enrolled in the Myocardial Iron Overload in Thalassaemia (MIOT) network and underwent hepatic iron overload assessment by the T2* Magnetic resonance Imaging (MRI) technique.
Results: The group with homozygous or compound heterozygous for β-thalassemia had the higher sTfR levels. sTfR values were negatively related to age at diagnosis (R=−0.462, P<0.0001), and to age at first transfusion (R=−0.703, P<0.0001). At ROC curve a sTfR>5.3mg/L discriminated the patients with a previous history of occasional transfusions. sTfR values were significantly higher in splenectomized patients. sTfR values were negatively related to age at splenectomy (R=−0.328, *P=0.044)* and in unsplenectomized patients a significant positive correlation was found between sTfR values and spleen diameter (R=0.572; *P<0.0001)*. sTfR values were negatively related to age at starting chelation therapy (R=-0.564, P=0.044). Patients never chelated showed significantly lower sTfR values than patients under chelation therapy (see Figure). sTfr values were significantly correlated with serum ferritin levels (R=0.321, *P<0.0001).* but no with LIC values.

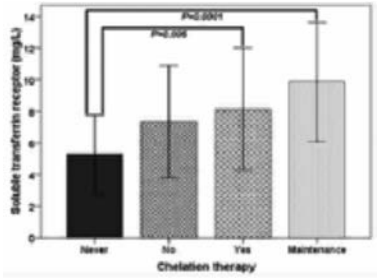

Figure 1.

Summary/Conclusions: The heterogeneity of patients with NTDT is an emerging cause of complex management and treatment of the disease. Our data indicate that the measurement of sTfR level, a common laboratory test, could contribute to correctly stratify the disease history and the chelation strategy in NTDT.

E1571

LOW SERUM FERRITIN LEVELS DO NOT PROTECT FROM CARDIAC AND HEPATIC IRON IN PATIENTS WITH THALASSEMIA MAJOR

A. Meloni[1,*], A. Spasiano[2], P. Ricchi[2], L. Pistoia[1], A. Carrà[3], C. Cosmi[4], R. Rosso[5], A. Scaccetti[6], V. Positano[1], R. Righi[7], S. Renne[8], A. Pepe[1]
[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]AORN A. Cardarelli, Naples, [3]Ospedale "G. Da Saliceto", Piacenza, [4]Azienda Ospedaliero-Universitaria di Sassari, Sassari, [5]Ospedale "Ferrarotto" - Azienda Ospedaliero-Universitaria Policlinico "Vittorio Emanuele", Catania, [6]Azienda Ospedaliera "S. Maria", Terni, [7]Azienda Ospedaliero-Universitaria Arcispedale "S. Anna-Cona", Ferrara, [8]Presidio Ospedaliero "Giovanni Paolo II", Lamezia Terme, Italy

Background: The estimation of serum ferritin levels is the most commonly employed test to evaluate iron overload in Beta Thalassaemia Major (TM).
Aims: The aim of this mulicenter study was to assess the distribution of serum ferritin levels in a cohort of well treated TM patients and the possible protective role of really low levels *versus* iron accumulation in the heart and in the liver.
Methods: We considered 1548 TM patients regularly transfused and chelated consecutively enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) Network. Myocardial and hepatic iron burdens were quantified by the T2* technique. For the heart a multislice approach was adopted in order to calculate segmental and global T2* values. Hepatic T2* values were converted into liver iron concentration (LIC) values.
Results: Mean serum ferritin levels <500ng/ml were found in 342 (22.1%) patients. Three groups were identified on the basis of mean serum ferritin levels. Both transaminases were significantly lower in patients with serum ferritin <500 ng/ml and between 500 and 1000 ng/ml *versus* patients with serum ferritin ≥1000 ng/ml. Among patients with serum ferritin <500 ng/ml, 9.1% showed significant cardiac iron (global heart T2*<20 ms) and 21.6% showed hepatic iron (LIC ≥3mg/g dw). Cardiac and hepatic iron levels were significantly lower in patients with serum ferritin <500 ng/ml than in the other two groups and in patients with ferritin between 500 and 1000ng/ml *versus* patients with serum ferritin ≥1000 ng/ml (see Figure). Compared to patients with serum ferritin levels <500 ng/ml, the other two groups showed a significant higher risk of cardiac iron overload (odds ratio-OR=2.03, P=0.002 for patients with ferritin 500-1000 ng/ml and OR=5.96, P<0.0001 for patients with ferritin ≥1000ng/ml) and of hepatic iron overload (OR=3.44, P<0.0001 for patients with ferritin 500-1000ng/ml and OR=25.43, P<0.0001 for patients with ferritin ≥1000ng/ml).

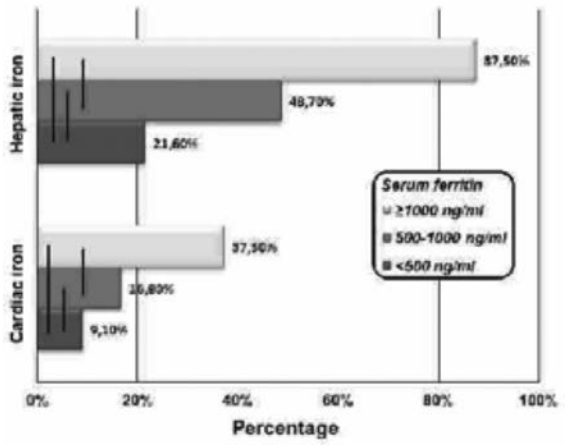

Figure 1.

Summary/Conclusions: Low serum ferritin values, even in the normal range, do not per se exclude cardiac and hepatic iron overload, although decreasing the risk. Before to consider a reduction of the chelator dose in patients whose serum ferritin levels have reached the target, a MRI scan should be performed in order to measure iron levels in the different organs.

E1572

ISCHEMIA MODIFIED ALBUMIN AS A MARKER OF OXIDATIVE STRESS IN CHILDREN AND ADOLESCENTS WITH B-THALASSEMIA: RELATION TO LIPID PEROXIDATION, IRON OVERLOAD AND VASCULAR DYSFUNCTION

A.A. M. Adly[1,*], N.H. Elsherif[1], E.A.R. Ismail[2], Y.A. Ibrahim[3], G. Niazi[4], S.H. Elmetwally[1]
[1]Pediatric Hematology&oncology, Faculty of Medicine, Ain Shams University, [2]Clinical Pathology Department, Faculty of Medicine, Ain Shams University, [3]Radiology Department, Faculty of Medicine, Ain Shams University, Cairo, [4]Radiology Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt

Background: Patients with β-thalassemia major (β-TM) are under significant iron driven oxidative stress. Ischemia modified albumin (IMA) is an altered type of serum albumin that forms under conditions of oxidative stress and an independent predictor of major adverse cardiovascular events
Aims: To measure the levels of IMA in 45 children and adolescents with β-TM compared with 30 healthy controls and assess its relation to lipid peroxidation, vascular complications and subclinical atherosclerosis
Methods: β-TM patients without symptoms of heart disease were studied focusing on transfusion history, chelation therapy, serum ferritin, malondialdehyde (MDA) and IMA levels. Echocardiography was performed and carotid intima media thickness (CIMT) was assessed.
Results: IMA and MDA levels were significantly higher in β-TM patients compared with controls (p<0.001). IMA was higher among patients with heart disease and pulmonary hypertension (PH) risk than those without. Serum IMA and MDA levels were elevated among patients with serum ferritin ≥2500 µg/L compared with patients below this cutoff. TM patients compliant to chelation had a significantly lower IMA levels than non-compliant ones. Receiver operating characteristic (ROC) curve analysis revealed that a cutoff value of IMA at 75 U/mL could differentiate β-TM patients with PH risk with 90% sensitivity,

91.4% specificity and positive predictive value of 75% and negative predictive value 97%; area under the curve 0.883 (95% confidence interval 0.752-0.959). In addition, the cutoff value of IMA at 17.5 U/mL could differentiate β-TM patients with heart disease with 80.5% sensitivity, 88.9% specificity and positive predictive value of 96.7% and negative predictive value 73.3%; area under the curve 0.887 (95% confidence interval 0.758-0.962). Significant positive correlations were found between IMA levels and disease duration (r=0.311, p=0.045), white blood cell count (r=0.322, p=0.031), serum alanine aminotransferase (r=0.388, p=0.01) and aspartate aminotransferase (r=0.382, p=0.037). IMA and MDA levels were positively correlated (r=0.503, p=0.001) and there was a significant positive correlation between these two markers and mean serum ferritin (IMA; r=0.645, p<0.001 and MDA; r=0.567, p<0.001) among TM patients. IMA levels were positively correlated to TRV (r=0.621, p=0.008), while negatively correlated to ejection fraction (r=-0.412, p=0.014) and fractional shortening. Both IMA and MDA were positively correlated to CIMT (r=0.607, p<0.001 and r=0.590, p<0.001, respectively).

Summary/Conclusions: Our results highlight the role of oxidative stress in the pathophysiology of vascular complications in thalassemia. IMA could be useful for screening of β-TM patients at risk of cardiopulmonary complications and atherosclerosis because its alteration occurs in early subclinical disease.

E1573

SERUM N-TERMINAL PRO-BRAIN NATRIURETIC PEPTIDE LEVEL AND ECHOCARDIOGRAPHIC TISSUE DOPPLER ABNORMALITIES IN PATIENTS WITH BETA THALASSEMIA MAJOR

M. El-Tagui[1], I. Mahmoud[2], H. Agha[1], S. Mohamed[1], M. El-Ghamrawy[1,*]
[1]Pediatrics, [2]Clinical and Chemical Pathology, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Heart disease remains the major cause of morbidity and mortality in thalassemia patients. Multiple pathologies have been implicated in the development of cardiac dysfunction in these patients including: cardiac iron overload leading to right ventricular diastolic then left ventricular systolic dysfunction, chronic anemia and tissue hypoxia. Because congestive heart failure is the main cause of death in these patients, early recognition of cardiac dysfunction may be useful in modifying therapy in a timely manner. Tissue Doppler imaging (TDI) echocardiography and serum brain natriuretic peptide (BNP) level may be promising tools for such a purpose.

Aims: This study aimed to assess serum NT-proBNP level and echocardiographic tissue doppler abnormalities among a cohort of Egyptian beta thalassemia major patients and to detect possible assocoations between them as well as other disease variables including iron overload.

Methods: Thirty beta thalassemia major patients with a mean age of 12.93±2.07 years regularly followed up at Pediatric Hematology Clinic, Cairo University and thirty aged matched healthy control subjects were included. Conventional, M-Mode and TDI echogardiography were performed to all patients and control subjects in addition to cardiac magnetic resonance (CMR)for studied patients. Serum NT-proBNP level was measured using enzyme linked immunosorbant assay (ELISA).

Results: Tissue doppler imaging revealed a significant difference of ratio of the early (e') to late (a') right ventricular filling velocities (Rv e'/a' ratio) between cardiac and non-cardiac iron overloaded patients reflecting early diastolic dysfunction in cardiac iron overloaded patients. Myocardial performance index of left ventricle (LV_TEI index) by TDI showed significant difference in cardiac iron overloaded patients compared to non cardiac iron overloaded patient (mean 0.45± .02 *versus* 0.39± .04 with p value=0 .003) indicating decrease in ventricular relaxation due to iron overload and restrictive cardiomyopathy. SerumBNP level was significantly higher among patients compared to controls (mean 99.18± 72.43pg/ml *versus* 18.93± 9.65pg/ml respectively with p-valu< 0.001) and among cardiac iron overloaded patients compared to non cardiac iron overloaded (mean 212.31±57.18pg/ml *versus* 64.75±26.69pg/ml respectively with p value <0.001). We found positive correlation between level of BNP and frequency of the blood transfusion/year, RVe'/a' and LV TEI_TD index with (p value 0.006, <0.001) and 0 .030 respectively) denoting early diastolic impairment in asymptomatic thalassemia patients.

Summary/Conclusions: Asymptomatic thalassemia major patients under chelation therapy may have diastolic and or systolic dysfunctions that could not be detected by conventional echocardiography but could be highlighted by TDI. CMR, TDI and serum BNP level measurement are promising tools for accurate assessment of cardiac functions and iron overload in thalassemia patients.

PRENATAL DIAGNOSIS OF HEMOGLOBINOPATHIES IN NORTHERN GREECE. 15 YEARS REPORT

S. Theodoridou[1,*], N. Prapas[2], A. Sotiriadis[2], A. Athanasiadis[2], T. Daglis[2], O. Karakasidou[1], E. Skatharoudi[1], D. Adamidou[1], M. Economou[1], A. Teli[1], B. Delaki[3], E. Boutou[3], E. Yfanti[3], A. Balassopoulou[3], T.-A. Vyzantiadis[4], T. Theodoridis[5], E. Voskaridou[3]
[1]Thalassemia Unit, [2]Obstetric Department, Hippokration General Hospital, Thessaloniki, [3]Thalassemia Centre, Laikon General Hospital, Athens, [4]Microbiology Department, [5]Obstetric Department, Aristotelion University, Thessaloniki, Greece

Background: Hemoglobinopathies constitute the most frequent monogenic disorders worldwide and thalassemias are the most frequent genetic disorders in Greece. Beta-thalassemia carrier frequency is approximately 8%, while 1.5% of the population are carriers of the Hb S mutation. The rate of β-thal carriers could be as high as 15-20% in some areas. The risk of giving birth to an affected child depends on the incidence of the thalassemic gene and this may vary from 1/24 to 1/150 in married couples. The National Program for prevention of Thalassemia was established in 1973. Through population screening and prenatal diagnosis programs Greeks and immigrants are screened and counseled.

Aims: We report our findings on prenatal diagnosis of thalassemias and hemoglobinopathies in Northern Greece over a 15 year period (2001-2015).

Methods: During the 15 year period, a total of 33.837 subjects were screened individually or as couples at our Thalassemia Prevention Unit. There were 3.659 couples screened for hemoglobinopathies. In 371 couples both partners carried an abmormal Hb gene and counseling was offered and 329 pregnancies were found at risk of giving birth to an affected child. The genes interactions were in 245 pregnancies at risk for thalassemia major offsprings and 84 for sickle cell disease ones. Prenatal diagnosis was mainly carried out by CVS at 11-12 weeks of gestation (n=298), in few cases by amniotic fluid sampling (n= 21) collected at 16-18 weeks. Few late comers were tested by fetal blood sampling at 20 week of gestation(n=5). The remaining 42 pregnancies involved couples who were double heterozygotes for mutations that did not cause severe clinical disease and were exempted from prenatal diagnosis. The gene interactions were as follows β-thal / α thal, β-thal in combination with Hb E-Saskatoon or D-Punjab, HbE /HbE, Hb E-Saskatoon /with carrier of HbS, and Hb O/ Hb O, β-thal or α thal in combination with D Punjab, Hb Brugg/β-thal, silent β-thal/ silent β-thal. 91% of the couples were of Greek origin, and 9% were immigrants from Albania, Somalia, Nigeria, Fyrom, Ruanta and Thailand. We had an average of 15-32 prenatal diagnosis per year.

Results: The results of DNA analyses of the samples were as follows: 76 fetuses (23%) were found to be homozygote or double heterozygote for clinical significant mutations. These couples were informed of the danger of having an affected child but the termination or continuation of the pregnancy was left to the couples to decide. Nevertheless all, except three couples, preferred to terminate the pregnancies so we had one case of thalassemia major offspring and two cases of silent β-thal/ O Arab offsprings born. Selective abortion of the affected fetus was performed in the cases of the twin pregnancies (n=6). There have been no cases of misdiagnosed pregnancies and only one obstetric complication (rupture of membrane that lead to miscarriage) was reported.

Summary/Conclusions: It is universally accepted that thalassemia prevention programs are successful in countries with a high frequency of Hb mutations, and prenatal diagnosis is mandatory in all at risk couples. The National Thalassemia Prevention Program has effectively decreased the incidence of thalassemia major and sickle cell syndromes in our country and in our region.

E1575

THE IMPACT OF LIVER STEATOSIS ON THE ABILITY OF SERUM FERRITIN LEVELS TO PREDICT LIVER IRON CONCENTRATION AMONG NON-TRANSFUSION-DEPENDENT THALASSAEMIA PATIENTS: A CROSS-SECTIONAL EVALUATION

P. Ricchi[1,*], A. Meloni[2], A. Spasiano[1], L. Pistoia[2], V. Positano[2], P. Preziosi[3], A. Filosa[1], A. Pepe[2]
[1]AORN A. Cardarelli, Naples, [2]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [3]Ospedale "Sandro Pertini", Rome, Italy

Background: Fatty liver is a common abnormality encountered in western countries among patients undergoing imaging of the abdomen and is associated to systemic inflammation and to increased ferritin levels, frequently unrelated to iron overload.

Aims: We analyzed the impact of the presence of fatty liver in the parameters of iron overload among our patients with Non Transfusion dependent Thalassaemia (NTDT).

Methods: 111 patients with NTDT were cross-sectionally evaluated; the diagnosis of liver steatosis was ultrasound-based (US). In all patients ferritin levels and serum alanine aminotransferase (ALT) to serum aspartate aminotransferase (AST) ratio were assessed. Liver iron concentration (LIC) measurements were available for 64 patients (54%) who underwent a magnetic resonance Imaging (MRI) scan within the Myocardial Iron Overload in Thalassaemia (MIOT) network.

Results: Liver steatosis was frequently (35.5%) encountered among our patients with NTDT and was significantly more prevalent in males with respect to females (49.0% *vs* 24.6%, p=0.008). Patients with liver steatosis had significantly higher levels of ALT, AST, ALT/AST ratio and ferritins than those without, but LIC values were comparable (Table 1). At ROC curve analysis, a ALT/AST ratio >0.89 predicted the presence of liver steatosis with a sensitivity=0.872 and a specificity =0.901 (P<0.0001). Overall, ferritin levels positively correlated with LIC values (R=0.558, P<0.0001) but in patients without steatosis there

was a strong relationship between ferritin and LIC values (R=0.656, P<0.0001) while in patients with steatosis the correlation was moderate (R=0.426, P=0.05).

Table 1.

	No steatosis (N=71)	Steatosis (N=39)	P-value
ALT (U/l)	14.80±5.29	31.74±16.42	<0.0001
AST (U/l)	21.29±7.73	27.97±11.27	0.001
ALT/AST ratio	0.72±0.16	1.12±0.35	<0.0001
Ferritin (ng/ml)	374.10±400.74	614.67±788.22	0.002
LIC (mg/g dw)	4.21±4.45 (N=41)	4.78±6.74 (N=23)	0.905

Summary/Conclusions: Our data show that liver steatosis affected also patients with NTDT and should be suspected in presence of a ALT/AST ratio >0.89. Recently, serum ferritin thresholds to predict clinically relevant liver iron concentrations for guiding chelation therapy when MRI is unavailable in patients with (NTDT) have been provided. Our data show that the presence of liver steatosis may lead to overestimate the magnitude of iron burden and may be responsible for anticipating or exceeding chelation treatment in patients with NTDT in absence of a LIC evaluation.

E1576

CIRCULATING CELL-FREE DNA (CFDNA) AND INEFFECTIVE ERYTHROPOIESIS IN BETA-THALASSEMIA INTERMEDIA

D. Tavazzi[1], G. Graziadei[2], A. Marcon[2], L. Duca[2], I. Nava[2], M.D. Cappellini[1,*], M. Sampietro[3]
[1]Dip. Scienze Cliniche e di Comunità, Università degli Studi di Milano, [2]Dipartimento di Medicina Interna, Fondazione IRCCS Cà Granda Policlinico di Milano, [3]Dip. Fisiopatologia Medico-Chirurgica e dei Trapianti, Università degli Studi di Milano, Milano, Italy

Background: Low concentrations of circulating cell-free DNA (cfDNA) are found in the plasma of healthy individuals and increase in a number of conditions in relation to clinical severity, including cancer, chronic inflammation, autoimmune diseases and trauma. The mechanisms of release of cfDNA in the bloodstream are not well understood: DNA could originate from cells undergoing apoptosis/necrosis in tissues or from cells released in the blood and subsequently lysed. Also the tissue origin of cfDNA is mainly unclear. It has been suggested that cfDNA, at least after bone-marrow transplantation, could be mostly of hematopoietic origin. This finding prompted us to explore whether cfDNA is increased in patients with ineffective erythropoiesis (IE), a condition characterized by the over-proliferation and lysis/removal of erythroid precursors. This situation is common in thalassemias, mainly in non transfusion-dependent patients (NTDT).
Aims: The present study was designed **i**) to evaluate the behaviour of cfDNA in IE caused by beta-thalassemia, and **ii**) to assess whether cfDNA could be useful to quantify IE.
Methods: We studied 49 beta-thalassemia intermedia (TI) patients (mean age 41 years, range 16-65), 23 of whom were splenectomized. No evidences of tumor, trauma or autoimmune diseases have been observed in any patient at time of the study. Eighteen healthy subjects were also included as control group. The study was approved by the local ethical committee. DNA was extracted by QIAgen silica-based micro-spin columns from 200 mL of K_2EDTA plasma and its concentration determined fluorometrically using the fluorescent dye PicoGreen. Biochemical and hematologic parameters were determined in all patients as a part of laboratory routine. Reticulocytes and peripheral erythroblasts (EBL) were counted by automated procedures. Soluble transferrin receptor (sTfR) and growth differentiation factor 15 (GDF15) were also measured by immunometric ELISA assays.
Results: In the 49 patients studied, plasma cfDNA concentrations ranged from 6.3 to 93.1 ng/mL and are significantly higher than in controls (median 21.8 *vs* 10.4, p<.0001). Comparing non splenectomised (non-SPX) with splenectomised (SPX) patients, we observed a significant increase of cfDNA in the SPX group (median 29.4 *vs* 19.3 ng/mL, p=0.0085). In the whole TI group, cfDNA concentration was significantly correlated with EBL (p<,0001), LDH (r=0.52, p=.0001) and AST (r=0.56, p<.0001). Correlations of cfDNA were also observed with sTfR (r=0.45, p=.0014) and GDF15 (r=0.56, p<.0001). Notably, correlations with EBL (r=0.75, p<.0001), AST (r=0.58, p=.0036) and unconjugated bilirubin (r=.54, p=.0083) were observed only within the SPX group and not in non-SPX.
Summary/Conclusions: In this study we found that plasma cfDNA rises in TI patients compared to controls. Its concentration appears to correlate with both the amount of IE based on high number of EBL and the lysis of circulating erythroid precursors (both increased after splenectomy). We obtained preliminary evidences that circulating cfDNA concentration may be a suitable indicator of erythropoietic activity in TI patients. Results need to be extended on larger samples of patients' population to investigate the possible use of plasma cfDNA as a feasible and reliable biomarker to describe/monitor the severity of IE and TI complications.

LEFT VENTRICULAR HYPERTRABECULATION BY CARDIAC MAGNETIC RESONANCE IN THALASSEMIA INTERMEDIA PATIENTS: FREQUENCY AND PROGNOSTIC ROLE

A. Meloni[1,*], F. Macaione[2], L. Pistoia[1], S. Pulini[3], V. Santamaria[4], M. Benni[5], L. Sardella[6], A. Barison[1], G. Peritore[7], V. Positano[1], S. Novo[2], A. Pepe[1]
[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Università Degli Studi Di Palermo, Policlinico Paolo Giaccone, Palermo, [3]Ospedale Civile "Spirito Santo", Pescara, [4]ASP Vibo Valentia, Vibo Valentia, [5]Policlinico S. Orsola "L. e A. Seragnoli", Bologna, [6]A.S.L. di Bari - Ospedale "Di Venere", Bari, [7]"ARNAS" Civico, Di Cristina Benfratelli, Palermo, Italy

Background: Differentiation of left ventricle non-compaction (LVNC) from hypertrabeculated LV due to a negative heart remodeling in thalassemia intermedia (TI) can depends on the selected CMR criterion. The recently proposed Piga's criterion (NC/C ratio threshold of >2.5, Am J Haem 2012) seems to have a low specificity to identify the true LVNC in TI. Anyway, the Piga's criterion could easily detect a negative heart remodeling in TI patients.
Aims: The aim of our study was to prospectively assess whether the Piga's criterion had a prognostic role for adverse cardiovascular outcomes in TI patients.
Methods: We studied prospectively 168 TI patients (81 males, mean age 38.32 ±11.61 years) consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network. Standard cine steady-state free precession sequences were acquired and used for the calculation of biventricular function parameters (short-axis) and for the calculation of the thickness of the non-compacted and the compacted myocardium (three diastolic long-axis views) in all 16 segments. The maximal NC/C ratio was considered. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

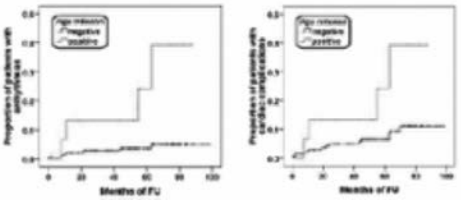

Figure 1.

Results: Eight patients were excluded because a cardiac complication was present at the first CMR. The baseline mean age of the considered 161 TI patients was 38.32±11.61 years and 81 patients were males. The study population was divided into two groups: patients with Piga's positive criterion (n=15, 9.31%) and with Piga's negative criterion (n=146, 90.68%). No significant differences were found between the two groups in terms of demographic features and CMR parameters. The mean follow-up time was 57.50±21.87 months. Sixteen new cardiac events were recorded: 1 heart failure, 10 supraventricular arrhythmias and 5 pulmonary hypertension. Due to numerical reasons, it was possible to perform a Cox regression analysis only for arrhythmias and cardiac complications globally considered. Patients with Piga's positive criterion had a significant higher risk of developing arrhythmias (hazard ratio-HR=7.19, 95% CI=2.02-25.51; P=0.002) and cardiac complications (HR=3.66, 95% CI=1.18-11.36; P=0.025). The figure shows the Kaplan-Meier survival curves. The Piga's positive criterion remained a significant prognosticator also in a multivariate models including previous and resolved events (14 cardiac complications, of which 7 arrhythmias) (HR for arrhythmias=23.67; HR for cardiac complications =7.09).
Summary/Conclusions: Based on our data a NC/C ratio >2.5 provides prognostic information for patients with TI about the risk of developing cardiac complications.

E1578

NITRIC OXIDE DYSREGULATION IN BETA-THALASSEMIA MAJOR: RELATION TO PULMONARY HYPERTENSION

M. Elshinawy[1,2,*], A. Elnaggar[3], A. Ghanem[3], M. Wagdy[4]
[1]Pediatric Hematology, Sultan Qaboos University Hospital, Muscat, Oman, [2]Pediatric Hematology, Faculty of Medicine, [3]Hematology, Medical Research Institute, [4]Clinical Pathology, Faculty of Medicine, Alexandria, Egypt

Background: Pulmonary hypertension (PH) is emerging as one of the most devastating complications of beta-thalasssemia major. Chronic hemolysis and iron overload constitute a major source of strong oxidative stress. Free heme radicals and red cell membrane elements resulting from hemolysis have a negative effect on the intrinsic nitric oxide (NO) production and arginine bioavail-

ability. Deficiency of both biochemical mediators promotes vasoconstriction of the pulmonary vasculature resulting in further endothelial dysfunction, with subsequent intensified reduction of nitric oxide. The role of nitric oxide dysregulation is well-studied in non-transfusion dependent thalassemias and in sickle cell disease, but yet not very well-characterized in beta thalassemia major.
Aims: The aim of our work is to study the relation between intrinsic nitric oxide level and the evolution of pulmonary hypertension in beta thalassemia major.
Methods: This is a case-control study, including all patients with beta thalassemia major above 12 years of age, undergoing follow up in pediatric hematology unit and in medical research institute, university of Alexandria, Egypt throughout a period of 6 months fom 1st of July till 31st of december 2016. All patients were screened for pulmonary hypertension by echocardiography, and those who have high tricuspid regurgitanr jet velocity (TRJV >2.5m/sec.) underwent cardiac catheterization.
Results: The present study included 52 thalassemic patients, 28 males and 24 females. Their age ranged between 11 and 26 years. The patients were subdivided into two groups (17 patients with pulmonary hypertension (PH), proven by cardiac cathetrerization and 35 patients without pulmonary hypertension). Nitric oxide level (measured by ELISA) was significantly lower in patients as a whole compared to controls [median of 19 micromol/L *versus* 30 micromol/L] (p=0.02). Similarly, nitric oxide was significantly lower in PH group compared to non-PH patients (p=0.001). In addition, there was a statistically significant negative correlation between serum NO level and serum ferritin level in all patients (r=-0.444, p=0.001).
Summary/Conclusions: In conclusion, NO reduction might contribute significantly to the development of pulmonary hypertension in patients with beta thalassemia major. This effect could be related to the degree of hemolysis, iron overload and the duration of disease. Further studies on the adverse pathophysiologic effects of nitric oxide deficiency in beta thalassemia major *e.g.* its relation to coagulopathy and platelet aggregation are recommended.

SPECKLE-TRACKING ECHOCARDIOGRAPHY FOR DIAGNOSIS OF EARLY MYOCARDIAL DISEASE IN EGYPTIAN BETA THALASSEMIA MAJOR PATIENTS

A.A.G. Tantawy[1,*], N.M. Habeeb[2], N.H. Elsherif[3], E.M. Hasan[1], A. Abdelhameed[1]
[1]Pediatric Hematology&oncology, [2]Cardiology departement, faculty of medicine,Ain Shams University, [3]Pediatric Hematology&oncology, Ain Shams University, Cairo, Egypt

Background: The new parameters of cardiac function, derived from two-dimensional speckle-tracking echocardiography could be useful for an early diagnosis of cardiac involvement in transfusion dependent β-TM patients.
Aims: In this cross sectional study, our goal was to detect early myocardial disease in transfusion dependent β-TM patients using Echocardiography (Speckle Tracking) and to assess its specificity and sensitivity in comparison with cardiac MRI T2*.
Methods: This cross sectional study included 30 transfusion dependant β-thalassemia patients aged between 11-20 years recruited from the Pediatric Hematology Unit, Children Hospital, Ain Shams University. All included patients were subjected to detailed medical history{including transfusion, chelation, hepatitis C virus history with calculation of mean serum ferritin in last 2years) Radiological investigation included Echocardiography (Tissue Doppler and Speckle Tracking),MRI T2* were done.Cardiac affection by speckled was defined as decreased longitudinal strain less than 11 percentage or affection of any segment less than 11 percentage.
Results: Cardiac affection by speckled echocardiography was found in 10 patients(33.3%), 8 of them (80%) had normal ejection fraction and normal shortening fraction ,while 9 had iron overload by Cardiac MRI T2*. Patients with mean serum ferritin>2500 ng/mL in the last 2 years prior evaluation showed a significantly lower longitudinal strain (GLPSLAX) (P=0.043) which was further proved by a significantly negative correlation with the mean serum ferritin (P=.002). No significant differences were found between both splenectomized and non splenectomized patients as regard speckle tracking echocardiographic measures. The ROC curve analysis revealed that GLPS A4C a cutoff value of ≤21% was able to detect B- thalassemia patients having myocardial disease by cardiac MRI T2* with a sensitivity of 87.50% and specificity of 63.64% .Patients with cardiac iron overload by MRI T2* had significantly lower GLPSLAX &GLPSA4C and higher Ao Diam than those without cardiac iron overload (P=0.016, P=0.008, P=0.047 respectively). No significant difference between beta thalassemia patients with cardiac affection and those without cardiac affection as regard the duration of the disease, type and compliance of chelation therapy.
Summary/Conclusions: Although, Magnetic Resonance Imaging T2* technique is still considered the reference standard in myocardial iron overload, its routine use is limited by its high costs, poor availability. We demonstrated in this study an abnormal global longitudinal strain despite preserved LV systolic functions among BTM patients; thus speckle tracking echo techniques might be considered as an alternative effective method to detect early myocardial disease before evident systolic dysfunction.

E1581

EFFICACY, SAFETY AND GENETIC BASIS OF VARIABILITY OF RESPONSE TO HYDROXYUREA THERAPY IN BETA THALASSEMIA: A SYSTEMATIC REVIEW

S. Khaliq[1,2,*]
[1]Pathology, fauji Foundation Hospital/Foundation University Medical College Rawalpindi, [2]Hematology, Hemophilia Centre, Rawalpindi, Pakistan

Background: Pharmacological agents such as hydroxyurea promote fetal hemoglobin production via a reactivation of γ-genes. In β-thalassemia there is an imbalance in globin chains which could be ameliorated by the newly synthesized γ-chains which neutralize the excess α-chains and therefore improves symptoms.
Aims: Systematic review of literature to evaluate the efficacy, safety and the genetic basis of variability of response to hydroxyurea therapy in beta-thalassemia patients
Methods: Research sources used were: MEDLINE (PubMed), EMBASE (Ovid) and Cochrane from June 1993 till June 2016. Eligible articles were reviewed and data including patients 'characteristics, duration of treatment, outcome, toxicity and impact of genetic mutation on response to hydroxyurea therapy was extracted. Major responders were those who became transfusion independent after hydroxyurea treatment, partial responders had significant decline in transfusion requirements, poor responders did not respond to hydroxyurea therapy. Statistical analysis software package 16 was used for data analysis.

Table 1.

Type of Beta Thalassemia	Major Response	Partial Response	Poor Response
b-thalassemia major	563 (52%)	359 (33%)	160 (15%)
b-thalassemia intermedia	620 (84%)	80 (11%)	38 (5%)

Results: Thirty eligible studies comprising of a total of 1822 patients with beta thalassemia were identified. Of these (n=9, 30%) evaluated the effect of hydroxyurea therapy on beta thalassemia major patients, (n=11, 36%) evaluated beta thalassemia intermedia patients while (n=10, 34%) included both beta thalassemia major and thalassemia intermedia patients. Mean age of patients was 13.5 years. Mean duration of hydroxyurea therapy was 3.4 years. The mean dose of hydroxyurea was 10mg/kg per day (8-15mg/kg). Table I showing number and percentage of patients having major, partial and poor response to hydroxyurea therapy. Only (n=12, 36%) studies evaluated the role of underlying genetic mutation on hydroxyurea response, out of these (n=6, 50%) studies found no significant correlation while (n=6, 50%) showed a positive correlation between common genetic mutations and hydroxyurea response. Hydroxyurea was found to be well tolerated, only (n= 09, 01%) had transient myelosuppression.
Summary/Conclusions: Hydroxyurea is an effective and well-tolerated agent in the management of β-thalassemia (both intermedia and major). It reduces blood transfusion requirements either partially or completely in majority of patients. No significant correlation between response to therapy and underlying genetic mutation was found. More studies are required to fully establish the association of genetic mutation to drug response.

E1582

EVALUATION OF CONTINUOUS BLOOD GLUCOSE MONITORING METHOD FOR DETECTION OF ALTERATIONS IN GLUCOSE HOMEOSTASIS IN BETA-THALASSEMIA PATIENTS

M. El Samahy[1], A. Tantawy[1,*], A. Adly[1], E. Ismail[1], A. Ahmed[1], N. Yousef[1]
[1]AinShams university, Cairo, Egypt

Background: Glucose metabolism disturbances, among other endocrinopathies, are a common feature of β-thalassemia major (β-TM). Pancreatic iron overload and diabetes mellitus (DM) are common in β-TM patients. However, the relationship between iron stores and glucose disturbances is not well defined. Continuous glucose monitoring system (CGMS) enables more diagnostic accuracy and a better achievement of an optimal glycemic control.
Aims: To assess the pattern of glucose homeostasis in patients with β-TM and detect early impairment in glucose metabolism and prediabetic state in β-thalassemia patients comparing oral glucose tolerance test (OGTT) and CGM system.
Methods: This cross sectional study was conducted on 200 patients β-TM patients. Patients were studied focusing on transfusion history, transfusion index, iron chelation therapy and compliance to chelation. Complete blood picture, markers of hemolysis, serum ferritin and random blood glucose (RBG) were measured. Patients with RBG ≥140mg/dL were subjected to OGTT, insertion of CGMS for 3 days, measurement of fasting C peptide, and serum insulin with calculation of HOMA-IR and assessment of HbA1c.
Results: Screening with RBG revealed that 20 patients (10%) had RBG ≥140mg/dL. Using OGTT, 7 (3.5%) patients were in the diabetic range, 7 (3.5%) had normal OGTT while 6 (3%) had impaired glucose tolerance. The CGMS showed that 7 (3.5%) patients had IGTT (6.5%) and 13 patients had diabetes

mellitus. The percentage of diabetic patients diagnosed by CGMS was significantly higher than that with OGTT (p= 0.012). According to CGMS readings, 10 of the 13 patients with diabetes had abnormal HbA1c readings of diabetic range (6.5-9.9%) while 5 of the 7 patients with impaired glucose tolerance had HbA1c readings in the prediabetic range (5.5-6.1%). Serum ferritin were significantly higher among patients with RBG ≥140mg/dL (p= 0.001). It was noted that 85% of patients with RBG≥ 140mg/dL were noncompliant and 75% of patients on desferrioxamine therapy had RBG≥140mg/dL. There was a significant positive correlation between HbA1C% and FBG among the studied thalassemia patients with elevated RBG≥ 140mg/dL, while HbA1c% was negatively correlated with fasting C-peptide. Serum ferritin was positively correlated with RBG. As regards CGMS data, HbA1C was positively correlated to maximum blood glucose, average blood glucose, SDS blood glucose and area under the curve≥140mg/dL. The only significant independent factor for elevated RBG ≥140mg/dL was serum ferritin.

Summary/Conclusions: The use of CGMS in the diagnosis of early glycemic abnormalities (prediabetes) among patients with β-TM appears to be promising and superior to other known diagnostic modalities namely OGTT and HbA1c.

E1583

LEFT VENTRICULAR REGIONAL FUNCTION IN CHILDREN WITH BETA THALASSEMIA WITH NO CARDIAC MANIFESTATIONS (FOUR-DIMENSIONAL ECHOCARDIOGRAPHIC STUDY)

M. El-Shanshory[1,*], O. Tolba [1], W. El-Shehaby[1], A. Elshamia [2], A. Fayed[3], A. ElKholy [4], E. Eldosoky[5]
[1]Pediatrics, Faculty of Medicine, Tanta University, Tanta, [2]Pediatrics, Ministry of Health, Basyoun, [3]Pediatrics, Ministry of Health, Kotor, [4]Pediatrics, Ministry of Health, Zefta, [5]Pediatrics, Ministry of Health, Alexandria, Egypt

Background: Early detection of myocardial dysfunction is essential for the management of patients with thalassemia. Four -dimensional echocardiography imaging technique that analyzes the motion of tissues in the heart may be useful for detecting subclinical cardiovascular disease.
Aims: To evaluate the 4-dimensional echocardiographic strain in children with beta thalassemia major and correlate it with other echocardiographic parameters.
Methods: This is a cross sectional cohort Study included 200 children, 1-18 years-old. They were divided into: One hundred children with β-Thalassemia major with no clinical cardiac manifestations and 100 healthy children as a control group. They were subjected to the following investigations: Complete blood count, serum ferritin and Four-dimensional echocardiographic strains (Longitudinal, Circumferential, Radial and Area strains).
Results: There was no significant difference between the two groups as regard mitral annulus systolic velocity (S wave), E/A ratio and iso-volumic acceleration but there was significant difference as regard to ejection fraction, left ventricle mass, sphericity index and myocardial performance index. The mean values of Left ventricular Strains (Longitudinal, Circumferential, Radial and Area strains) were significantly lower in patients with thalassemia (-14.86±12.131, -8.01±3.829, 33.13±10.613, -19.45±6.866) than controls (-19.13±1.502, -16.32±1.34, 37.28±4.209, -22.94±3.064) than controls respectively with a positive correlation with 2-Dimensional strain.
Summary/Conclusions: Strain parameters of the left ventricle obtained by four-dimensional echocardiography can be a novel and promising technique for early detection of left ventricular dysfunction in children with thalassemia.

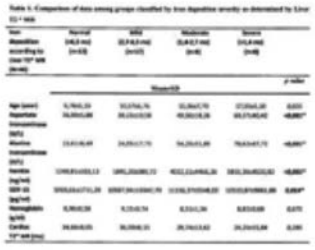
E1584

THE IMPORTANCE OF SERUM GDF-15 LEVELS TO ASSESS IRON OVERLOAD IN PATIENTS WITH THALASSEMIA MAJOR

M. Ucman[1], U. Caliskan[2,*], H. Tokgoz[2]
[1]Necmettin Erbakan University Meram Medical Faculty, Konya, Turkey, [2]Pediatric Hematology and Oncology, Necmettin Erbakan University Meram Medical Faculty, Konya, Turkey

Background: There is growing interest in noninvasive assessment of iron accumulation in patients with thalassemia major. Magnetic resonance imaging (MRI) have become widely available in recent times.
Aims: We aimed to evaluate the importance of serum GDF-15 levels for monitoring the iron overload in patients with beta thalassemia major.
Methods: Forty-six patients aged between 1 and 25 years were included in the study. Serum levels of GDF-15, ferritin, troponin, AST and ALT were studied. T2*MRI was performed for all patients. The relationship between GDF-15 hormone levels and T2 * MR, ferritin levels, sex, annual transfusion volume, splenectomy was evaluated.
Results: Of 46 patients, 20 were male (%43,5) and 26 were female (%56,5), with a median age of 12,4 years. Mean serum ferritin level was 2752, 15±3105,78 ng/ml. Mean GDF-15 level was 9672,87±7910,36pg/ml. Mean duration of T2*MRI was 32,50±11,33 ms for hearth and 4,87±3,78 ms for liver. 12 patients were underwent splenectomy. Serum GDF 15 levels were significantly higher in thalassemia major patients than in normal levels. According to T2*MRI levels, serum GDF-15 levels were significantly higher in patients with hepatic iron overload. There was a negative correlation between hepatic T2*MR values and serum GDF-15 levels. However, there was not significant correlation between cardiac T2*MR and serum GDF-15 levels. Splenectomy had no effect on GDF-15 levels (Table 1).

Table 1.



Summary/Conclusions: We demonstrated that serum GDF-15 levels were increased in thalassemia major patients. GDF-15 levels is correlated with hepatic iron overload but not cardiac iron overload. It may be due to lower number of thalassemic patients with abnormal cardiac T2* MRI. GDF-15 may be a valuable parameter to assess iron overload in thalassemia major, but further studies are needed.

E1585

ASSOCIATION OF SP1 POLYMORPHISM IN THE COLLAGEN TYPE I ALPHA -1 (COLIA1) GENE WITH OSTEOPROSIS IN CHILDREN WITH BETA-THALASSEMIA

M. Hesham[1,*], N. Khalifa[2], M. Zakaria[1], N. Elbaz[2], D. AbdElmonem[2]
[1]Pediatric, [2]clinical pathology, Zagazig University Hospital, Zagazig, Egypt, Zagazig, Egypt

Background: Osteoporosis is a progressive bone disease that is characterised by a decrease in bone mass and density that leads to an increased risk of fracture. Early detection of mutation at the Sp1-binding site on the *COLIAI* gene is mandatory in order to initiate preventive therapy before the occurrence of fractures in children with beta-thalassemia.
Aims: To study the relationship between SP1 polymorphism in the collagen type 1 alpha 1 gene and the development of osteoporosis in patients with Beta thalassemia.
Methods: A prospective case control study was carried out in the Outpatient Clinic of Hematology Unit of Pediatric Department and Clinical Pathology Department at Zagazig University Hospitals on forty thalassemic patients (21 females &19 males) aged 6-18 years during their regular follow-up visits (22 patients with thalassemia major and 18 with thalassemia intermedia)and forty age- and sex-matched healthy children as a control group. All patients and control were subjected to full medical history, thorough clinical examination and laboratory investigations in the form of complete blood count, Hb electrophoresis, Calcium level Serum ,alkalin phosphatase, Bone Density by DXA, Serum osteocalcine level and *COLIAI* gene polymorphism by using polymerase chain reaction-restriction fragment length polymorphism technique (PCR-RFLP).
Results: There was highly significant difference between thalassemia patients and control group as regards serum levels of calcium, osteocalcin and alkaline phosphatase and DEXA results but no significant difference between thalassemia major and thalassemia intermedia patients. As regard COLIA1 genotype there was high percentage of heterozygous Ss (G/T) and homozygous ss (T/T) genotype in beta thalassemia major 55.63%, 13.67% than thalassemia intermedia 50.6%, 0%, respectivily. There was significant relation between COLIA1genotypes and Calcium level (p=0.02). But there was no significant relation between COLIA1genotypes and osteocalcin, alkaline phosphatase levels and DEXA among studied groups.
Summary/Conclusions: SP1 polymorphism in collagen gene could be of clinical value in identifying the thalassemic patients at risk of developing osteoporosis.

Estefânia, Centro Hospitalar de Lisboa Central, [6]Fac-

uldade de Medicina, Universidade de Lisboa, [7]Serviço de Gastroenterologia, Hospital de Santa Maria, Centro Hospitalar de Lisboa Norte (CHLN), [8]Serviço de Hematologia, Hospital de Santa Maria, CHLN, [9]BioISI, Faculdade de Ciências, Universidade de Lisboa, [10]ToxOmics, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, [11]ISAMB, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal

Background: Hemoglobin (Hb) is a protein responsible for oxygen transportation from lungs to the entire body. It is composed by four globular subunits - the globins - each with a central core containing a heme molecule. Globins are encoded by the α- and β-globin gene clusters located at 16p13.3 and 11p15.5, respectively. The pattern of globin gene expression during development is precisely controlled by the interaction of *cis*-regulatory genomic regions (located in close proximity to and far from genes) with *trans*-activating/silencing factors within permissive chromatin domains. Distally upstream of the α-globin genes there are four multispecies conserved sequences (MCS-R1 to R4) which are critical for the expression of the downstream globin genes. Deletions removing the α-globin genes and/or their distal MCSs give rise to α-thalassemia, one of the most common genetic recessive disorders worldwide, due to a reduced rate of α-globin chain synthesis. The severity of the pathology is variable ranging from a very mild microcytic hypochromic anemia to a moderately severe anemia associated with the formation of β_4 tetramers resulting in HbH disease or an even higher reduction or complete absence of α-chains resulting in hemoglobin Bart's hydrops fetalis, a condition generally incompatible with life.
Aims: The main objectives of this work were to characterize the molecular lesions underlying ten Portuguese cases of unusual α-thalassemia/HbH disease and to understand their origin and functional consequences.
Methods: After exclusion the most frequent molecular lesions associated with α-thalassemia, Multiplex Ligation-dependent Probe Amplification (MLPA) using the SALSA MLPA P140B HBA kit (MCR-Holland) was used to search for DNA deletions in the subtelomeric region of chromosome 16p. Additionally, specifically designed synthetic MLPA probes, as well as gap-PCR and Sanger sequencing were performed for more accurate deletion breakpoint mapping.
Results: We have found five distinct deletions and one indel, all in heterozygosity. The deletions range from approximately 3.3 to 323 kb and two of them are novel. The three larger deletions remove the entire α-globin cluster whereas the others remove totally or partially the distal regulatory elements keeping the α-globin genes structurally intact. The indel comprises the deletion of the MCS-R2 regulatory element and the insertion of a singular 39 bp DNA fragment possibly originating from a complex rearrangement involving chromosome 3. Finally, no α-globin gene cluster deletion or point mutation were found in a patient who revealed to be a very unusual case of acquired alpha-thalassemia associated with a myelodysplastic syndrome.
Summary/Conclusions: Our study widens the spectrum of molecular lesions and unusual molecular mechanisms by which α-thalassemia/HbH may occur and emphasizes the importance of diagnosing large α^0-deletions to provide patients with appropriate genetic counseling.

VALUE OF HBA2 IN THE DIAGNOSIS OF BETA-THALASSEMIA MINOR "ATTENTION TO THE GRAY ZONE"

L. Relvas[1,*], T. Magalhães Maia[1], E. Cunha[1], J. Pereira[1], A.C. Oliveira[1], C. Bento[1], M.L. Ribeiro[1]
[1]Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: The homozygosity for the alternative splicing mutation *HBB*: IVSI-6 (C>T) is the most frequent genotype of beta thalassemia intermediate in our population and was even termed "beta thalassemia intermediate type Portuguese" (Tamagnini et al, 1983). The IVSI-6 (C> T) carriers (heterozygous) are characterized by mild hypochromia and microcytosis, with a moderately increased in HbA2, that may be even less than 3.5%. The correct identification of these carriers is important, especially when facing a couple who intends to have children.
Aims: To evaluate the percentage of individuals with hypochromia and microcytosis and Hb A2 between 3.2% and 3.4%, who are beta thalassemia carriers, alerting for the need to adapt the cut-offs of HbA2 values to the genetic background of different populations.
Methods: Parameterized search of all the consecutive individuals evaluated in our laboratory from January 2007 to January 2016. The inclusion criteria were the simultaneous presence of hypochromia and microcytosis (adjusted to the age) and HbA2 values between 3.2% and 3.4% inclusive. The exclusion criteria were the presence and/or clinical information of sideropenia or sideropenic anemia, hemoglobin variants or alpha thalassemia. Sequencing of the entire HBB gene was preformed by Sanger Sequencing.
Results: Respecting the inclusion and exclusion criteria we have identified 43 individuals with hypochromic and microcytic anemia, HbA2 ≥3.2% and ≤3.4%, in which the *HBB* gene mutations were screened. Among the 43 subjects, nineteen presented HbA2=3.2% (19/43), eleven HbA2=3.3% (11/43) and thirteen had HbA2=3.4% (13/43). The IVSI-6 (T>C) mutation was identified in 2 subjects with HbA2=3.2% (10%), 5 with HbA2=3.3% (45%) and 7 with HbA2=3.4% (54%). No other *HBB* gene mutations were detected. The remaining individuals were classified as probable alpha thalassemia and suggested continuation of the study, if warranted.
Summary/Conclusions: We have identified 14/43 (32%) individuals as beta thalassemia carriers who, for the conventional cut-off of HbA2 ≥3.5%, would not have been diagnosed. Based on this data, we propose that individuals with hypochromia and microcytosis, with normal or slightly elevated RDW, without sideropenia, with HbA2 between 3.2-3.4%, should be screened for mutations in the *HBB* gene, in order to rule out beta thalassemia carriers due to Beta+ mutations. As *HBB* IVSI-6 (T>C) mutation is one of the most frequent beta thalassemia mutations in Portugal, and in Mediterranean basin, it is necessary to keep in mind that the classic rule of HbA2> 3.5% for the diagnosis of beta thalassemia minor may underdiagnose this pathology and lead to an incorrect genetic counseling.

E1589

DIAGNOSIS OF HEMOGLOBINOPATHIES BY CAPILLARY ZONE ELECTROPHORESIS: EXPERIENCE WITH 925 CASES

P. Tripathi[1,*], H.P. Pati[1], R. Saxena[1]
[1]Dept of Hematology, All India Institute of Medical Sciences, New Delhi, India

Background: Hemoglobin capillary zone electrophoresis is a relatively newer technique as compared to HPLC for detection of abnormal hemoglobins. We share our first hand experience of using Capillary 2 Flex piercing instrument for diagnosis of hemoglobinopathies as a primary diagnostic modality
Aims: The main aim was to evaluate a new technology for diagnosis of hemoglobinopathy.
Methods: The capillary 2 Flex piercing instrument with Phoresis software for hemoglobin electrophoresis at alkaline pH was evaluated at our centre over a period of 1 year. A total of 925 sample runs were included in the analysis. The equipment was assessed on the following parameters: ease of operation, pre-analytical factors, identification, quantification and precision of hemoglobin variants including the rare variants. Further, we evaluated if capillary zone electrophoresis can be useful as a single method for diagnosis of hemoglobinopathies.
Results: The automation provided by capillary zone electrophoresis eased the problem of errors during sample preparation. The option for low sample volume mode is a great help in samples from children. The instrument could readily identify all common hemoglobins and the diagnosis was straightforward in 829 (89.7%) cases. In the rest 96 (10.3%) cases, the sample was required to be rerun because it lacked Hb A or Hb A2. This posed inconvenience because the electrophoretic zones get displaced and have to be derived after mixing it with normal sample. The machine is not specifically standardized for cord blood samples hence we are not performing tests on neonatal cord blood sample.
The instrument could separately identify Hb E from Hb A2 which is a big scorer over HPLC, however, we found mild high Hb A2 both in heterozygous and homozygous Hb E cases (heterozygous Hb E, n-28 mean Hb A2- 3.9% and homozygous Hb E, n- 7 and mean Hb A2- 4.2%) leaving the doubt whether some adducts are still left. Identification of small peaks of Hb H could be difficult and requires other modalities to confirm. Two cases where Hb H was strongly suspected clinically and HB H inclusion test was positive showed small peaks of HB H (1.2% and 0.9%) on HPLC. Hemoglobins falling into the same zone (eg Hb D- Punjab and Hb Q India) needed identification with second modality. Whenever encountered with problem of identifying certain abnormal peak, we resorted to HPLC for confirmation. Spectrum of hemoglobin variants encountered (n-298 cases, rest 627 showed normal results) in the study is listed in table below.

Table 1.

	Type of Hemoglobin	No of cases (n- 298)
1.	Beta Thalassemia	194
2.	Hemoglobin S	30
3.	Hemoglobin E	35
4.	Hemoglobin D	9
5.	Hemoglobin J Meerut	4
6.	Hemoglobin H	4
7.	Hemoglobin Q India	2
8.	Haemoglobin Lepore	3
9.	Hereditary persistence of fetal hemoglobin	1
10.	Compound heterozygotes (eg Hb E-beta thalassemia or Hb S- beta thalassemia)	16

Summary/Conclusions: Capillary zone electrophoresis is an alternative method which brings automation. However, since the diagnosis of Hemoglobin variants mandates confirmation by a second method, HPLC cannot be replaced completely. Based upon the availability, workload and cost effectiveness, any of these two methods can be used as primary modality.

Thrombosis and vascular biology

E1590

RELEVANT ROLE OF VON WILLEBRAND FACTOR-ADAMTS13 AXIS IN HEPATIC ISCHEMIA- REPERFUSION INJURY

Y. Urisono[1,*], H. Matsui[2], K. Nishio[2], K. Okuchi[1], M. Sho[3], M. Sugimoto[2]
[1]Emergency and Critical Care Medicine, [2]General Medicine, [3]Surgery, Nara Medical University, Kashihara, Japan

Background: Hepatic ischemia-reperfusion (I/R) injury is a liver damage occurring during liver surgeries such as hepatic resection or transplantation, and denotes the major basis for graft dysfunction after transplantation. Although detailed mechanisms of hepatic I/R injury remain to be clarified, an excessive inflammatory response is thought to play a role in this regard.
Aims: Since recent studies suggest that von Willebrand factor (VWF) plays a pivotal role in a cross-talk between inflammation and thrombosis, we assumed that VWF may be involved in the pathophysiology of hepatic I/R injury. To test this hypothesis, we have used a mouse experimental model of hepatic I/R injury.
Methods: Mice were anesthetized with sodium pentobarbital and a midline laparotomy was then performed on a heating pad. Blood supply for left lateral and median lobes of liver (approximately 70% of the liver mass) was interrupted by cross-clamping the hepatic artery and portal vein with a microvascular atraumatic clip for 90 min. Then a clip was taken off to provoke the reperfusion of hepatic blood flow, which was monitored on the surface of left lateral lobe by Laser Doppler flowmetry (ALF21, Advance Co, Tokyo, Japan). The hepatic blood flow was measured again 24 h after reperfusion and mice were then sacrificed for blood collection and histological analysis of liver tissue. We compared 16 wild-type (WT) and 12 VWF-gene deleted (knock-out; KO) mice (from The Jackson Laboratory, Bar Harbor, ME), all of which were 8-12 weeks of age, healthy and fertile. Excess blood loss was not observed in all mice (WT or KO) during whole surgical process.
Results: As compared to WT mice, restoration of hepatic blood flow was significantly greater in VWF-KO mice at 24 h after reperfusion (WT; 61± 17% *vs* KO; 87±17%, expressed as the percentage of pre-ischemic value). Consistent with the hepatic blood flow, the time-course analysis of serum alanine aminotransferase (ALT) at several time points after reperfusion revealed the lesser liver damages of KO mice (WT; 6898±3270 and 1313±621 IU/L *vs* KO; 3043±1320 and 478±330 IU/L, at 3 h and 24 h after reperfusion, respectively). In addition, histological analysis confirmed that neutrophil infiltration in the liver tissue of KO mice was significantly reduced as compared to WT mice at 24 h after reperfusion. These impaired hepatic blood flow and ALT values as well as intensified neutrophil infiltration in WT mice were significantly improved to an extent comparable to those of KO mice by the bolus injection of recombinant human ADAMTS13 (3 μg/mouse equivalent to 2800 U/kg, n=12) just prior to the I/R operation.
Summary/Conclusions: Our results altogether indicate that VWF-dependent inflammatory responses with neutrophil recruitment at ischemic sites are involved in pathophysiology of hepatic I/R injury, and functional regulation of VWF by ADAMTS 13 may serve as a promising therapeutic option for hepatic I/R injury.

E1591

THE IMPORTANCE OF THE FULL BLOOD COUNT, JAK II AND ADAMTS 13 TESTING IN STROKE EVALUATION: A REVIEW OF 619 CONSECUTIVE YOUNG STROKE AND TIA PATIENTS

A. Taylor[1,*], V. Alakbarzade[2], A. Chandratheva[2], R. Simister[2], A. Dados[2], M. Scully[1]
[1]Haematology, [2]Neurology and Stroke Medicine, University College London Hospital, London, United Kingdom

Background: Young ischaemic stroke patients undergo extensive investigations yet around 40% remain of undetermined cause. Complex and costly thrombophilia testing is routinely sent despite limited evidence linking to arterial disease. A full blood count may be ignored but is potentially more helpful in suggesting myeloproliferative disease or thrombotic thrombocytopenic purpura (TTP) as causative.
Aims: We retrospectively reviewed full blood counts, specifically haematocrit and platelet count, and whether these were documented and further investigated if outside of the normal laboratory range. We examined whether less common primary haematological disorders known to cause stroke were considered: JAK II mutation analysis for myeloproliferative diseases such as polycythaemia vera (PV) and essential thrombocythaemia (ET), and ADAMTS13 analysis for TTP.
Methods: We retrospectively reviewed consecutive clinical and laboratory records for all stroke and TIA patients <60 years presenting to a regional hyperacute stroke unit and daily TIA clinic from January 1st 2015- August 7th 2016. All those with thrombocytosis (defined as platelet count >400x10^9/L) and/ or raised haematocrit (defined as Hct >0.45) were reviewed to see if a cause could be determined, and if not, whether JAK II analysis was considered and tested. We similarly examined patients presenting with thrombocytopenia (defined as platelet count <150x10^9/L), and if no cause determined, whether ADAMTS13 testing was contemplated.
Results: 610 patients <60 years were included: 379 ischaemic stroke (62.1%), 193 TIA (31.6%) and 38 haemorrhagic stroke (6.2%). 161 (26.4%) had abnormalities in haematocrit or platelet count: 116 (19%) had a raised haematocrit, 19 (3.1%) thrombocytosis, and 26 (4.2%) thrombocytopenia. Of these, 7 patients demonstrated abnormalities of both cell lines. Of these initial 161 abnormal results, 119 (73.9%) were repeated but 42 (26.1%) were not. JAK II testing was deemed warranted in 17 (2.8%): a persistently raised or progressively raised haematocrit or platelet count respectively, with normal liver and renal function and no other explicable cause. JAK II mutational analysis was performed in 3 patients (0.5%). One was proven positive for the V617 F mutation, hence diagnosed with polycythaemia vera. Of the 2 negative JAK II results, one patient was subsequently diagnosed with chronic myeloid leukaemia. Fourteen patients had no further testing or monitoring. 26/610 (4.3%) patients had thrombocytopenia. ADAMTS13 testing was not warranted in 17 of these (subsequent resolution of platelet count n=7, HIV n=2, liver derangement n=7, known ITP with no MAHA n=1). ADAMTS13 testing was indicated in 9 of these patients (34.6% of thrombocytopenic patients), defined as a persistent thrombocytopenia with no clear cause, normal liver and renal function and negative HIV status. Seven of these patients did not have ADAMTS13 considered, according to the clinical documentation, nor sent. Of the 2 tested for ADAMTS13, one result was normal, helping to resolve the clinical diagnosis of ITP. In the other patient, ADAMTS13 was <5%, confirming TTP and facilitating life-saving plasma exchange to take place.
Summary/Conclusions: In stroke patients <60 years, one quarter had abnormalities in haematocrit or platelets. Myeloproliferative disease or TTP was present in 3 patients of 5 specifically investigated in the cohort. From a haematological perspective, at least 21 further patients merited further investigation. However, this number may be higher since a quarter of those patients with initial discrepancies of haematocrit and/ or platelet count did not have repeated testing. Although primary haematological disorders are rare as a cause of stroke, a basic full blood count result should not be ignored in considering the aetiology of arterial thrombosis in a younger cohort.

E1592

PERIPHERALLY INSERTED CENTRAL CATHETER (PICC) RELATED THROMBOSIS IN 230 PATIENTS WITH HEMATOLOGICAL MALIGNANCIES. A 6 YEARS SINGLE EXPERIENCE CENTER

M. Baile[1], Á. Veiga[1], M. López-Parra[1], M. Sánchez-Barba[2], N. Arratibel[1], B. Rodríguez[1], M. Sastre[1], Ó. Del Rey[1], A.Á. Martín[1], M. Cabrero[1], J.R. González-Porras[1], J.M. Bastida[1,*]
[1]Hematology, Hospital Universitario de Salamanca, [2]Statiscal, University of Salamanca, Salamanca, Spain

Background: The use of peripherally inserted central catheters (PICCs) is widely extended in patients with hematological malignancies, not only to be treated with chemotherapy, blood cell transfusions, but also parenteral nutrition support or frequent analytical extractions. However, catheter-related thrombosis is one of its main complications. There are a few studies that evaluate this complication. We reported the experience of the PICC-related thrombosis (PRT) in our center.
Aims: To analyze the incidence of PRT, describe the clinical characteristics and management of these patients and identify the risk factors of PRT.
Methods: We performed a retrospective chart review of 230 adult patients diagnosed with hematological malignancies, in whom, experimented nurses tunneled PICCs with different technique: blinding Seldinger from 2010 to 2014 and guided by ultrasonography (US) from 2015 to 2016. PRT diagnose was confirmed by Doppler US. Statistical analysis was performed using the SPSS program (v.20).
Results: The median age was 58 years (14-86) and 55.7% of the patients enrolled in the study were male. The most frequent hematological malignancies were: Non-Hodgkin's lymphoma (NHL=105; 45,7%) myeloid malignancies (acute myeloid leukemia and myelodysplastic syndromes (AML/MDS=60; 26,1%), acute lymphoblastic leukemia (ALL=22; 9,6%), multiple myeloma (MM=19; 8,3%) and Hodgkin lymphoma (HL=17; 7,4%). In 188 patients (82%), PICC was tunneled when the active disease was presented. Only 51 patients (22%) received thromboprophylaxis based on low molecular weight heparin (LMWH=27), aspirin (ASA=21) or vitamin K antagonist (VKA=3). PICCs were tunneled guided by US in 127 patients (55,2%), and the main location of tip catheter was in cava-right atrium region (66%). The overall incidence of PRT was 7% (n=16). The main diagnoses related to PTR were ALL (6), NHL (5), and HL (3). All except one had active disease when PICC was tunneled (15/16=94%). Fourteen patients (88%) were treated by chemotherapy based in L-asparaginase (L-ASA), immunomodulatory drugs or other treatment combined with corticosteroids. The median onset of PRT was 26 days, (range: 0-230) and 8 of them (50%) in the first 30 days after insertion. In 11 cases (69%) D-Dimer was elevated. All PICC were removed within 72 hours of PRT and treated with LMWH to a median of 4 months (range: 1-11). During follow-up, no patient had progression of thrombosis, or pulmonary thromboembolism. Finally, in the univariate analysis ALL, HL and L-ASA had significant impact on

PRT (LLA:OR 15,75; CI 2,91-85,12; p= 0,001; HL:OR 9; CI 1,38-58,78; p=0,022; L-ASA:OR 7,82; CI 2,45-24,95; p=0,001). However, in the multivariate analysis, HL was the only risk factor of PRT (OR 8,38; CI 1,05-66,5; *p*=0,044).
Summary/Conclusions: Patients with HL may be predisposed to developing PRT compared with those with other types of hematological malignancies. Identifying the mechanism underlying this relationship will require further study.

E1593

A STUDY OF VENOUS THROMBOEMBOLISM SUSCEPTIBILITY LOCI FACTOR XI, ABO AND FIBRINOGEN IN A PORTUGUESE POPULATION SAMPLE
L. Manco[1,*], C. Silva[2], P. Martinho[3], T. Fidalgo[3], A.B. Sarmento[2,3], M.L. Ribeiro[1,3]
[1]Research Center for Anthropology and Health (CIAS), [2]Faculty of Medicine, University of Coimbra, [3]Serviço Hematologia Clinica, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal

Background: Venous thromboembolism (VTE) is a multifactorial disease caused by environmental/acquired risk factors and complex gene-gene and gene-environment interactions. VTE results from the development of a thrombus, usually in the deep veins of the leg (deep vein thrombosis, DVT) that can subsequently embolise to the lung (pulmonary embolism, PE). Classical inherited risk factors for VTE in European-ancestry populations include protein C and S deficiencies, factor V Leiden and prothrombin gene mutation (FII G20210A). Several other common and low-frequency susceptibility variants, mainly single nucleotide polymorphisms (SNPs) in loci *ABO,FXI, FII, FV, FGG, GP6, KNG1, PROCR, SLC44A2, STXBP5,TSPAN15* and *VWF,* have been also found robustly associated with VTE. However, in the Portuguese population, the genetic background for VTE for most of these genetic susceptibility variants remains to be evaluated.
Aims: To investigate the association of five SNPs in the loci ABO (rs2519093 and rs8176719), FXI (rs2036914 and rs2289252) and FGG (rs2066865) with VTE in a sample of Portuguese patients.
Methods: A retrospective (2012-2015) case-control study with 119 cases of unprovoked VTE and 148 healthy controls of Portuguese origin was conducted, to evaluate allele frequencies of the five VTE risk alleles in the Portuguese population and to assess the association between these alleles and the risk for VTE. FXI (rs2036914 and rs2289252) and FGG (rs2066865) SNPs were genotyped by real-time PCR with TaqMan probes. *ABO* rs2519093 and rs8176719 SNPs were genotyped by restriction fragment length polymorphism (RFLP). PLINK software was used to determine the allelic frequencies, concordance with Hardy Weinberg equilibrium and association between risk alleles and VTE through logistic regression, in the additive model, estimating OR with 95% confidence intervals (95% CI) and *p*-values. The association between the cumulative number of risk alleles and the risk of VTE was assess through Pearson χ^2 using the *Simple Interactive Statistical Analysis software* (SISA).
Results: The estimated risk allele frequencies in the overall study population sample were: 0.212 for *FGG* rs2066865 (T), 0.62 and 0.50 for *FXI* rs2036914 (C) and rs2289252 (T), respectively, and 0.295 and 0.417 for *ABO* rs2519093 (T) and rs8176719 (C), respectively. The genotype distributions were in agreement with the Hardy-Weinberg equilibrium (P>0.05) for all SNPs. The logistic regression under an additive model showed that *FGG* rs2066865 was associated with VTE (nominal *p*=0.029; OR=1.57, CI 95% 1.05-2.37) as well as *ABO* rs8176719 (nominal *p*=0.0064; OR=1.65, CI 95% 1.15-2.36). Both SNPs remain significantly associated when adjusting for age and sex (P=0.019 and P=0.0065, respectively). ABO rs2519093 did not reach significant association with VTE in our population sample (P=0.184) as well as *F11* rs2036914 and rs2289252 SNPs (P=0.76 and P=0.16, respectively). In addition, there was an increased risk of VTE associated with the increment in the total number of risk alleles: 0 *vs* 1 risk allele: X^2=5.8, *p*=0.015, OR=2.31; and 0 *vs* 2 or more risk alleles: X^2=12.2, *p*=0.00048, OR=3.36).
Summary/Conclusions: Our data suggest that the alleles *FGG* rs2066865 T and *ABO* rs8176719 C may contribute to the VTE susceptibility in the Portuguese population. The absence of significant associations for the remaining loci could be the result of a limited statistical power, consequence of a modest effect size of polymorphisms or lower sample sizes, or because of differences in genetic backgrounds between populations.

E1594

PEDIATRIC VENOUS THROMBOEMBOLISM: INCIDENCE, RISK FACTORS AND MANAGEMENT OF HOSPITALIZED PATIENTS IN A TERTIARY CARE TEACHING HOSPITAL
P. Raheja[1,*], P. Olivera[1], V. Pons[1], E. Johansson[1], T. Canals[1], F. Bosch[1], A. Santamaria[1]
[1]Hematology Department, Vall d'Hebron University Hospital, Barcelona, Spain

Background: Venous thromboembolism (VTE) is considered a rare event in childhood. In spite of this, the incidence of VTE is on the rise in hospitalized patients. Medical progress in the treatment of critically ill patients has increased the use of central venous catheters (CVC) and interventional procedures, especially in children with cardiac defects and malignant disease. Therefore VTE is increasingly recognized as a major secondary complication of advanced tertiary care in infants and children.
Aims: To study the incidence, demographics, risk factors, diagnostic tests, therapy, and complications of pediatric acute VTE in our tertiary care hospital.
Methods: A retrospective single-center study of patients<18 years of age who were discharged from January 2014 to December 2016 by using diagnostic codes for acute VTE from our hospital database. We studied demographic characteristics, clinical presentation, diagnostic tests, risk factors, treatment strategies and outcome.
Results: We report an incidence rate of 10.7 cases per 10,000 patient-years (70 acute VTE events / 21,892 discharge cases over a 3-year period). Patients were predominantly male (57%). Mean patient age was 3.3 years, with the greatest proportion of cases, 54.3%, in the infant cohort (from 1-12 months), while children above 1 year comprised 37% and neonates (<1 month) formed 8.6% of our sample. Patients were mostly born at full term (71.4%), although 45.7% of the neonatal and infant cases were premature. Catheter-related (CVC-VTE) comprised 55.7% of VTE cases. On the other hand, non-catheter-related (NCR) diagnoses were most frequently intracranial in 35.5% of cases, in inferior extremity deep vein thrombosis (DVT) in 29% and intracardiac in 19.3%. Only 3 cases of NCR-pulmonary embolism (PE) and 2 cases of NCR-upper extremity DVT were reported. Doppler ultrasound was the most common diagnostic test used (75.7%), followed by MRI, CT and CT angiography in equal proportions. Critically ill patients encompassed most of the cases (88%). Mean duration of hospitalization was 89 days (range 2-156) and time from admittance to VTE diagnosis was 25.6 days. A large proportion had congenital heart defects (32.9%) requiring interventional procedures. Half of the patients (51.4%) had surgery around the time of VTE diagnosis. Malignancy was identified in 5 cases (2 of which were CVC-VTE). Transient triggers, such as infection (12 cases) and use of asparaginase (2 cases) were also reported. Most patients were not tested for thrombophilia (n=44, 62.9%) since they were classified as provoked VTE and from those who were tested 10% were diagnosed with a thrombophilia. All except for one patient initiated anticoagulant therapy: 78.6% (n=52) were initially treated with low molecular weight heparin (LMWH) and while most continued treatment with LMWH, 8.6% (n=6) received vitamin K antagonists and 8.6% received direct oral anticoagulants. LMWH dosing was adjusted using anti-Xa assays (AXA) in 85.7% of cases, documenting a median of 5 AXA per patient, out of which 3 were within therapeutic range. Mean duration of treatment was 5.8 months. Recurrence rate was 17%, half of which were in patients with CVC-VTE. On the other hand, bleeding rate was 15.7% most of which were mild (10%) or provoked bleeds (4.3%). Mortality was 10%, although cause of death was not directly related to VTE in any of the cases.
Summary/Conclusions: Pediatric VTE is a substantial complication arising from tertiary care hospitalization where critically ill infants are at greater risk. Potential risk factors of VTE include use of CVCs, patients with complex congenital heart defects, surgical procedures, infection and malignancy. Further studies on VTE prophylaxis and identification of VTE predictors in a critical care setting are required.

E1595

CELL-BASED EVALUATION OF CHANGES IN COAGULATION ACTIVITY INDUCED BY ANTINEOPLASTIC DRUGS FOR THE TREATMENT OF ACUTE MYELOID LEUKEMIA
H. Shinki[1,*], M. Tsunaka[1], T. Koyama[1]
[1]Graduate School of Health Care Sciences, Tokyo Medical and Dental University, Tokyo, Japan

Background: Idarubicin (IDR), cytarabine (AraC), and tamibarotene (Am80) are effective for treatment of acute myeloid leukemia (AML). In acute leukemia, the incidence of venous thromboembolism or disseminated intravascular coagulation is associated with induction chemotherapy.
Aims: How some drugs for the treatment of AML affect the procoagulant activity is unclear. Thereby, in this study, we investigated the procoagulant effects of IDR in comparison with AraC and Am80.
Methods: Procoagulant effects of IDR, AraC, and Am80 were investigated in a vascular endothelial cell line EAhy926 and AML cell lines HL60 (AML M2), NB4 (AML M3, APL), and U937 (AML M5), focusing on tissue factor (TF), phosphatidylserine (PS), and thrombomodulin (TM). Normal human plasma-based recalcification time assay, flow ctytometric anayses, and RT-PCR are applied for the evaluation.
Results: IDR induced procoagulant activity on the surface of vascular endothelial and AML cell lines. Expression of TF antigen, TM antigen, and PS were induced by IDR on the surface of each cell line, whereas expression of TF and TM mRNAs were unchanged. Increased TF and PS expression may overcome increased TM expression and the overall effect may be procoagulant. Conversely, Am80 decreased TF exposure and procoagulant activity, and increased TM exposure on NB4 cells. In NB4 cells, we observed downregulation of TF mRNA and upregulation of TM mRNA by Am80. But Am80 did not sufficiently exhibit anticoagulant activity on NB4 cells when applied simultaneously with IDR.
Summary/Conclusions: These data suggest IDR may induce procoagulant activity in vessels by apoptosis through PS exposure and/or TF expression on vascular endothelial and AML cell lines. Am80 may suppress blood coagulation through downregulation of TF expression and induction of TM expression. Our methods could be useful to investigate changes in procoagulant activity induced by antineoplastic drugs.

DESCRIPTION OF THROMBOTIC EVENTS AND/OR PREGNANCY LOSSES IN A COHORT OF HOMOZYGOUS CARRIERS FOR THE C46T POLYMORPHISM OF THE F12 GENE

S. Martín Herrero[1,*], D. Velasco-Rodríguez[1], R. Vidal[1], C. Blas[1], J.M. Alonso-Domínguez[1], A. García Raso[2], P. Llamas[1]
[1]Hematology, [2]Health Care Institute, Fundación Jiménez Díaz, Madrid, Spain

Background: The intrinsic pathway of coagulation is initiated by a serine protease named factor XII (FXII) in a reaction involving the contact system and triggers fibrin formation through activation of factor XI. In vitro, FXII triggers activation of the classic complement pathway and initiates the fibrinolytic system via plasma kallikrein mediated urokinasa activation, whereas *in vivo* its role remains uncertain. A C—>T polymorphism at nucleotide 46 in the 5'-untranslated region of the F12 gene (F12 C46T) is associated with lower levels of FXII. Its frequency varies widely across populations and ethnic groups, ranging from 0.18 in the Spanish population to 0.67 among Japanese. Homozygosity for the C46T polymorphism of the F12 gene has proved to be an independent risk factor for thrombosis and unexplained recurrent spontaneous abortion. However, the precise role of this polymorphism as a thrombotic risk factor is controversial, and the evidence for an association between F12 C46T, venous thromboembolism (VTE) and myocardial infarction is weak.
Aims: To describe the occurrence of thrombotic events and/or pregnancy losses and the existence of other risk factors for thrombosis in a cohort of homozygous individuals for F12 C46T.
Methods: We retrospectively analyzed all the homozygous F12 C46T cases diagnosed in our laboratory from January 2015 to January 2017. Allelic discrimination PCR with TaqManmgB probes was performed to detect homozygous individuals for F12 C46T mutation. The following variables were collected: age, gender, race, cardiovascular risk factors (CVRF) (hypertension, diabetes mellitus, dyslipidemia, smoking and overweight), history of cancer, VTE (type, recurrence), arterial thrombosis, familiar history of thrombosis, number of pregnancy losses and other inherited/acquired thrombophilia.
Results: 122 cases were evaluated: 45 (36.88%) male and 77 (63.12%) female. Mean age: 46.2 years (1-86). Race: 65.57% caucasian, 13.1% american, 2.4% black, 1.6% asiatic, 4.1% other. Decreased factor XII plasma levels were found in 81.42% of them, with mean factor XII levels 53.73% (27.5-107.5). Overall, 34.48% of the subjects had at least one thrombotic event. Type of thrombosis: 64.4% VTE and 35.6% arterial thrombosis. One (26.7%) or more than one (46.7%) additional thrombotic risk factors were found in patients with any thrombotic event. Presence of one or more CVRF was found in 66.7%. Familiar history of thrombosis was found in 16%, whereas 13% had a recent or active malignant neoplasm. Among women, 28.57% and 12.98% had one and more than one pregnancy loss respectively. Additional thrombotic risk factors were found in 60% of women with recurrent losses. One (43%) or more than one (13%) additional thrombotic risk factors were found in women with any pregnancy loss. Presence of one or more CVRF were found in 30% of them. Familiar history of thrombosis was found in 34.7%, whereas none of them had a recent or active malignant neoplasm.
Summary/Conclusions: Most patients with a thrombotic episode had one or more additional risk factors. Nevertheless, up to 26.7% presented no other risk factor than homozygous F12 C46T, suggesting a relevant role in the pathogenesis of thrombosis. According to our results, the risk of abortion could be increased by the presence of homozygosity for F12 C46T, since it was the only thrombotic risk factor in 40% of women with recurrent pregnancy losses. Further studies are needed to clarify the real contribution of F12 C46T to thrombosis and pregnancy losses on prospectively selected patients.

E1597

ANALYSIS OF CHARECTERSISTICS OF HOSPITAL ASSOCIATED THROMBOSES

Neil Smith[*,1], Charelampos Kartsios[1]
[1]Haematology, Heart of England NHS Foundation Trust, Birmingham, United Kingdom

Background: Hospital associated thrombosis (HAT) is now commonly monitored but expected targets of HATs remains poorly reported.
Aims: We analysed HATs in our hospital group over a 40 month period to assess any trends or paterns of HAT incedence and charecteristics over time.
Methods: We reviewed all VTE episodes in 2013-2017 across our hospital group, identifying those patients with hospital-associated thrombosis (HAT), defined as patients having had a hospital inpatient episode, including day case surgery and admissions of 4-24 hours, in the 90 days prior to their VTE episodeRoot cause analysis was undertaken on these cases, recording information of the index episode including risk assessments performed and the corresponding prescribing and administration of thromboprophylaxis (TP) consisting of LMWH or GCS.
Results: Results: a total of 2222 VTEs were identified (1051 PE's and 1178 DVTs) of which 581 (26%) HATs were identified (312 PE's, 269 DVT's). This represents an excess of PEs over the expected rate based on total VTE distribution between PE and DVT (p=0.0002 Fishers exact test). The majority of patients had a medical (non-surgical) index admission with 58.5% admitted as acute medical admissions and 41.5% surgical admission (trauma and orthopaedics 18.4%, general, vascular and GI surgery 12.2%, urology 4% and Obstetrics and gynaecology 4%). Not all surgical patients underwent operations. In 526 HAT cases, root cause analysis (RCA) revealed that 101 (19.2%) were deemed preventable and 367 (69.8%) were not thought to be preventable. The remaining 57 cases had the index admission outside of our trusts, largely having orthopaedic procedures which were not included in further analysis.
Of 394 HAT cases with sufficient data, 80 (20.3%) had a preventable cause, 27 receiving insufficient TP, 9 receiving delayed TP, 26 having no TP given though indicated and 18 not having a VTE risk assessment. Some cases of insufficient TP were deemed due to underdosing standard patient >90kg. Off those HAT cases deemed unpreventable, 37 patients had contraindications to TP, 166 had TP failure i.e. full TP given and in 102 TP was not indicated. 9 patients were on full anticoagulations at time of index admission.
Summary/Conclusion: HAT rates remain stable and the majority are though unavoidable by cureent techniques. Key errors in avoidable cases are failure to perform a timely VTE risk assessment and action with appropriate thromboprophylaxis. Full integration of electronic patient records with electronic prescribing modules may reduce further these errors.

E1598

THROMBOSIS DURING INFANCY AND NEWBORN PERIOD: AN UNRESOLVED ISSUE

F. Gumruk[1,*], S. Aytac[1], I. yaman bajin[1], B. Kuskonmaz[1], S. unal[1], S. yigit[2], M. yurakok[2], M. cetin[1]
[1]Pediatric Hematology, [2]neonatology department, Hacettepe University, Ankara, Turkey

Background: Reported incidence of thrombosis is higher among newborn infants that can be explained by age related deficiency of anticoagulants, overproduction of procoagulants and deficiency/ dysfunction of fibrinolysis in addition to exposure to multiple risk factors and wide use of catheters which may eventually lead to the transient prothrombotic phenotype in this age group.
Aims: Our aim is to evaluate clinical and laboratory data, risk factors, outcomes of infants (>1-≤12months) and newborns(≤1month) with thrombosis in our center.
Methods: Our database revealed 752 children having various types of thrombosis between January 2003 to December 2015 and 77 out of 752 were diagnosed as thrombosis under one year of age. We retrospectively evaluate their clinical and laboratory results by searching their paper based & electronic files. Thrombotic risk factors included inherited and acquired hypercoagulable states, catheter, infection, trauma, surgical operations were also recorded.
Results: There were 51 male and 26 female with a median age of 4 months (0-12 months) in this group. Among 77 thrombotic events 22 (28%) were observed during neonatal period (≤1month) with a male predominancy (n=15, 68%) and from those 22 events 2 were arterial thrombosis (purpura fulminans(1), cerebral(1)) whereas 4 intracardiac, 5 sinovenous and 11 venous thrombosis (deep veins(4), renal veins(3), portal veins(3) cerebral vein(1)) were noted. In 2(9%) thrombosis was diagnosed on the first day of life and 11 out of 22 patient had underlying risk conditions such as prematurity(3), perinatal hypoxia(2), necrotizing enterocolitis(1), congenital cardiac disorders(3),congenital nephrotic syndrome(1) and adrenal insufficiency(1).Moreover 6 out of these 22 thrombotic event catheter insertion was the associated risk factor and 4/22 had infection. Factor V Leiden mutation was found to be homozygous in 1/18 and normal in 17/18. Heterozygous prothrombin 20210A mutation were detected in 1 out of 18 and homozygous MTHFR C677T mutation was found in 3/13 patient. Half of them 12(%54) were initially treated with LMWH and TPA were used as a thrombolytic agent in 5 case without any complication. During the follow up period 1patient had an amputation, 5 patient decased; one because of sepsis and the rest 4 had primary disesase and thrombosis .The site of location in 55 thrombotic events during the infancy period involved deep venous thrombosis (22), cerebral sinovenous thrombosis (10),cardiac(8), portal(3), renal(1) veins and cerebral arterial (7),femoral arterial(3),abdominal aortic thrombosis(1).In this group 42(76%) out of 55 had an underlying disorder and most common associated risk factor for this age group was inserted catheter related thrombosis, infection and surgical operations.Initial treatment choice was LMWH in 25(45%) and during the median follow up time of 2 years 10 had chronic thrombosis, 21 resolved, 10 had parsiel thrombosis, 4 deceased and 10 loss to follow up.
Summary/Conclusions: During the first month of life thrombotic complications is 40 times higher than at any other pediatric age. As previously reported venous thrombosis which mainly affect the limbs, the right atrium and renal veins are more frequently seen than arterial thrombosis in newborn infants with a male predominancy is compatible with our findings. In the absense of randomized clinical trials the choice of anticoagulation and the duration of treatment for this age group is still controversy beside the complex mechanism and a high mortality&morbidity rate. Although clinical and laboratory data of neonates were compatible with infants, treatment choices differ between these two groups and it sems that thrombolytic treatment was tend to be used more commonly in the neonates without any complication.

E1599

THE QUALITY COMPOSITION OF SOLUBLE FIBRIN MONOMER COMPLEX FRACTION FOR ACUTE AND POST ACUTE ISCHEMIC STROKE PATIENTS

T. Katrii[1,*], T. Vovk[1], O. Savchuk[1]

[1]Biochemistry, Educational and Scientific Centre "Institute Of biology and medicine", Kyiv, Ukraine

Background: Soluble fibrin monomer complexes (SFMC) are the early marker of thrombophilia that represent the complexes of monomeric fibrin with fibrinogen or their products of degradation (FDP). SFMC levels are not directly affected by therapy with thrombolytic agents. Detection of SFMC formed due to the activation of blood clotting by thrombin reveals a pathological process in the early, preclinical stages.
Aims: We explored the quality difference between the SFMC fraction obtained from acute ischemic stroke patients and one year post acute phase of stroke in the absolutely the same patients.
Methods: SFMC fraction was obtained from each tested groups: 35 healthy donors as well as 66 patients with atherothrombotic ischemic stroke (AIS) and 56 patients with cardioembolic ischemic stroke (CIS) during the acute phase of disease; 56 patients with AIS and 56 patients with CIS one year past acute phase. SFMC were collected from blood plasma of each tested subtypes of ischemic stroke by incubation with 0,78% o-phenanthroline per 5 min. For Size-exclusion chromatography SFMC in volume 1 ml was applied on Healthcare Life Sciences "HiLoad 16/60 Superdex 200 pg" column.
Results: Results suggest presence of proteins with Mr from 45 up to 330 kDa in SFMC fraction. The content of SFMC was similar for all stroke fractions with some exception. The difference between results of separation of stroke factions and fractions obtained from healthy donors was obvious. Mostly the proteins content of the SFMC fraction is similar for stroke and healthy fractions. But amount of the proteins as mean peaks high is different (Figure 1). In fact, the first three peaks whitch correspond to the 330, 280 and 250 kDa of chromatogram of SFMC are common for all tested fractions and were verified only in their height. Accordingly, the most widely represented variations peaks for AIS, even a year after stroke soluble fibrin monomer complex content was higher comparing to the healthy donors index. Healthy donors also had some of these complexes, but in trace amounts. For acute CIS situation was similar as for AIS, but past one year it got closer to healthy donors.

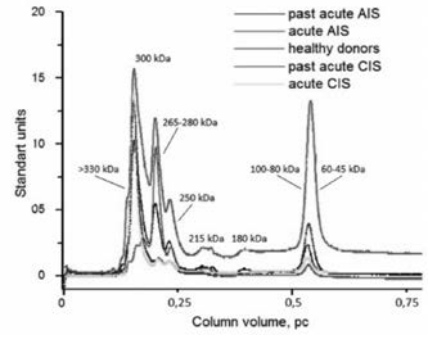

Figure 1.

Summary/Conclusions: It was shown that development of ischemic stroke accompanied by the formation of SFMC in the bloodstream that could take part in disease complication.

E1600

EVALUATION OF A RAPID NANOPARTICLE-BASED LATERAL FLOW IMMUNOASSAY (STIC EXPERT HIT) FOR THE DIAGNOSIS OF HEPARIN-INDUCED THROMBOCYTOPENIA IN A CARDIOTHORACIC HOSPITAL

G. Soufla[1,*], M. Katafygioti[1], S. Georgantis[1], T. Kanellopoulou[1], T. Kostelidou[1]
[1]Department of Haematology, Blood Transfusion Unit and Coagulation and Haemostasis, Onassis Cardiac Surgery Center, Athens, Greece

Background: Heparin Induced Thrombocytopenia (HIT) is a severe complication of heparin anticoagulation treatment that could be life threatening. HIT diagnosis is therefore of crucial importance in clinical practice especially for the cardiothoracic patients that are often exposed to heparin before surgery (e.g. during a PTCI). Laboratory testing for the presence of IgA, IgM and IgG or IgG only antibodies against PF4/Heparin (namely HIT antibodies) along with the 4Ts scoring system (Thrombocytopenia, Time of platelet count fall, Thrombosis, Other cause of thrombocytopenia) is used to evaluate the probability of HIT syndrome. At the Onassis Cardiac Surgery Center the methods for routine laboratory testing for HIT comprise Enzyme-linked Immunoassay testing for IgG, IgA, IgM HIT antibodies and Heparin-Induced Platelet Aggregation assay for the presence of platelet activating antibodies.
Aims: We evaluated a rapid nanoparticle-based lateral flow immunoassay (Stic Expert HIT) for assessing the presence of IgG antibodies to PF4/Heparin in patients plasma or serum in cases of emergency diagnosis of HIT needed for patients requiring urgent cardiothoracic surgery over a six-month period.
Methods: Stic Expert HIT, a rapid-nanoparticle based lateral flow immunoassay was performed on plasma from 35 patients from July 2016until January 2017 and the reading was done independently by two different technicians or biologists. The diagnosis of HIT was confirmed when both H/PF4 ELISA and the 4Ts score were positive.
Results: In 22 cases the Stic Expert was negative for the presence of IgG H/PF4 antibodies in the patients' plasma and HIT syndrome was easily excluded in combination with the "4Ts". In the rest 13 cases the rapid test provided doubtful results that were considered as positive and then H/PF4 ELISA was performed. Following the ELISA test, 10 out of the remaining 13 patients were found negative for the presence of IgG H/PF4 antibodies, whereas 3 patients were found positive with a relative low O.D. value (0.400). The last 3 patients that were positive for the presence of IgG H/PF4 antibodies by ELISA were found not to have HIT syndrome in combination with the '4Ts" scoring system.
Summary/Conclusions: In conclusion the Stic Expert HIT was useful for the quick exclusion of HIT (along with the 4Ts scoring system) when emergency HIT diagnosis is needed in 34% of the cases (12/35) in our Hospital. However in the rest 13/25 (66%) of the cases, laboratory testing for HIT was much more complicated and time consuming since ELISA or other assays (i.e.HIPA test) had to be performed. Nevertheless all 13 patients were found not to suffer from the HIT syndrome with the "4Ts' scoring system.

E1601

AUDIT OF 'DOOR TO NEEDLE' TIME IN ADMINISTRATION OF PROTHROMBIN COMPLEX CONCENTRATE TO PATIENTS REQUIRING URGENT REVERSAL OF ANTICOAGULATION

S. Elshafie[1,*], N. Smith[1]
[1]Haematology, Heart Of England Nhs Foundation Trust, Birmingham, United Kingdom

Background: Anticoagulants are used to treat or prevent thrombotic events but their most worrying side effect is major haemorrhage. The British Committee for Standards in Haematology (BCSH) recommend reversal of major/life threatening bleeding in both VKAs and DOACs with Prothrombin Complex Concentrate (PCC).
Aims: We aim to reduce delays in the administration of PCC in our trust and introduce the term 'Door To Needle' time (DTN) in the context of anticoagulant reversal.
Methods: We analysed the DTN in bleeding anticoagulated patients defined as time of recognition of haemorrhage to PCC administration. In Heart of England NHS Foundation Trust between May and July 2016, 29 patients were included; 19 patients were taking Warfarin and 10 taking DOACs. All patients received PCC (Beriplex®).
Results: Sixty-nine percent of patients were male and 31% female. The majority (69%) of patients were treated for stroke prevention in AF and 24% had a history of VTE. The two commonest major haemorrhage types were cerebrovascular (including intracranial and subdural haemorrhage) in 36% and gastrointestinal bleeding in 39%. The remaining indications (25%) were pre-urgent procedure/surgery, and soft tissue haematoma. The average time for recognition of haemorrhage was 3 hours 20 minutes (range 4 minutes to 21 hours 27 minutes), and the DTN was 4 hours 50 minutes (range 33 minutes to 13 hours 24 minutes), which means an estimated average of 6 hours 27 minutes (range 2 hours 49 minutes to 13 hours 59 minutes) between hospital admission and receiving PCC. Six of the total number of patients died within 30 days of hospital admission, 4 taking on Warfarin and 2 taking on DOACs.
Summary/Conclusions: This audit demonstrates the continuing delays between recognition of major/life-threatening bleeding events and receiving PCC since previous audits despite raising staff awareness. We plan to introduce the term 'DTN' in the context of anticoagulant reversal, store PCC in the emergency department pharmacy cupboards (as a PoM) as opposed to blood bank, and introduce a reporting system 'Serious Hazards of Warfarin (SHOW)' which may further reduce delays, morbidity and mortality.

E1602

THE IMPORTANCE OF PLATELET MEMBRANE FLUIDITY AND OXIDATIVE STRESS IN THROMBOTIC COMPLICATIONS ACQUIRED BY CHRONIC MYELOPROLIFERATIVE NEOPLASMS PATIENTS

V.M. Popov[1,*], M. Andreescu[1], M. Omer[1], A. Trifa[1], F. Mihai[1], C. Dragan[1], O. Patrinoiu[1], M.G. Moisescu[2], T. Savopol[2], E. Kovacs[2], H. Bumbea[3], A.M. Vladareanu[3]
[1]Hematology, Colentina Clinical Hospital, [2]Biophysics and Biotechnology Department, [3]Hematology, UMF Carol Davil, Bucharest, Romania

Background: Patients with chronic myeloproliferative neoplasms (MPNs) and chronic myeloid leukemia (CML) have a variety of structural and functional abnormalities of platelets. Many of them have thrombotic or hemorrhage complications. Platelet function is influenced by changes in membrane fluidity (MF) which has an important role in the expression of platelet receptors, modulating the activity of protein membrane.
Aims: The importance of reactive oxidative species (ROS) in alteration function of platelet membrane and expression of platelet receptors in patients with MPNs and CML.
Methods: We present a retrospective study on 36 cases MPN (20 JAK2-positive MPN) and 24 CML admitted in Colentina Clinical Hospital Bucharest. The determination of platelet membrane fluidity was performed by fluorescence anisotropy measurements using as marker 1-(4-trimethylammoniumphenyl)-6-phenyl-1,3,5-hexatriene p-toluenesulfonate (TMA-DPH). We analyzed the fluorescence anisotropy of platelet membrane and correlate the result of with a

different kind of treatment. Production of ROS was examined using fluorescence method with DCFDA and Fluorolog spectrophotometer Platelet receptor expression was analyzed by flowcytometric method studying adhesion marker (CD 42 and CD 42b) and aggregation marker (CD61, CD41).
Results: Patients with MPN and JAK2 mutation present have a high level of fluorescence anisotropy than the JAK-negative group. Median value for JAK2 positive MPN group 147.2 95% CI for median value (138.7-150.6)) *vs* JAK2 negative MPN group 130.8 (124.6-138.3) p=0.001. There are no differences between CML and MPN group. Our results confirm that fluorescence anisotropy is influenced by medication taken. MPN patients who have taken Hydroxyurea alone had a high-level fluorescence anisotropy than the patient who have taken association Hydroxyurea and Anagrelide; median value and 95% CI for median value 151 (137.1-158.6) *vs* 136 (126-137.5) p=0.03. A patient who have treatment with tyrosin kinase inhibitor (TKI) - Sprycel or Glivec, had a low level of fluorescence anisotropy, median value and 95% CI for Hydroxyurea group 151 (137.1-158.6) *vs* TKI group value 138 (124.4-147.8) p=0.04. No differences of fluorescence anisotropy was observed between the group of MPN patients who received JAK inhibitor (Jakavi) or Hydroxyurea The CD42b expression is low in patients *versus* controls (median: 17.87% *vs* 94.16%, P<0.01), there is no difference in the CD42a value range (P=0.51). The CD61/CD41 expression (GP IIb-IIIa) presents also lower values in patients (median: CD 61= 84.13%; CD 41=71.13%) *versus* controls (median: CD 61= 98%; CD 41=93,17%), statistical significance obtained only for CD61 expression.Production of ROS is higher for patients with MPNs and CML patients compared with healthy controls. CML patients in accelerate or blastic phase have higher level of ROS production compared with patients in chronic phase (1.23 *vs* 1.09, p=0.03). Our results of anisotropy measurements did not reveal any influence of ROS in MF modifications (0.15 *vs* 0.13, without statistical significance) or with platelet receptor expression.
Summary/Conclusions: The presence of JAK 2 mutation in MPN patient is associated with a low fluidity of platelet membrane. Association of Anagrelide or TKI inhibitor is associated with lower level of fluorescence anisotropy. The fluidity of platelet membrane could be an important parameter which influenced the expression of platelet receptor. We have to observe in the future if this group with high level of fluorescence anisotropy had a high risk of thrombosis. All these results will be verified in a higher patients lot and need to be checked any correlation between modification of fluidity membrane production ROS and expression of microparticles platelet derivated.

E1603

USE OF ROTATIONAL THROMBOELASTOGRAPHY TO PREDICT CENTRAL VENOUS CATHETER RELATED VENOUS THROMBOSIS IN CHILDREN: PRELIMINARY RESULTS

T. Bayhan[1,*], B. Oguz[2], F. Gumruk[1], M. Cetin[1], A. Gunes[2], I.Y. Bajin[1], F.N. Kalkan[1], S. Unal[1]
[1]Division of Pediatric Hematology, [2]Department of Radiology, Hacettepe University, Ankara, Turkey

Background: Central venous catheters (CVCs) have been widely used in hospitalized pediatric patients, however, CVCs increase venous thrombosis frequency. In pediatric age group exact risk factors for CVC related venous thrombosis haven't been shown yet. Rotational thromboelastography (ROTEM®) measures clot formation and stability and evaluate cogulopathy.
Aims: We aimed to predict CVC related venous thrombosis via ROTEM prospectively in pediatric age group patients.
Methods: Study included patients who required CVC insertion due to any reason and who were not on any anticoagulation treatment during the week before the CVC insertion. On the day of CVC insertion clotting time (CT), clot formation time (CFT), maximum clot firmness (MCF), and alpha angle (AA) were measured for intrinsic (INTEM), extrinsic (EXTEM), and fibrinogen (FIBTEM) pathways via ROTEM. At one week of insertion and at removal of CVC, Doppler ultrasound imaging was performed to the vein that catheter was removed.
Results: A total 14 patients were included in the study. Median age was 3.9 years (0.3-17.8 years). Ten (71%) of the patients had juguler, four (29%) patients had femoral CVC. Median duration until removal of CVC was 15.5 days (7-56). Thrombosis was detected in one patient (7%) at first week of CVC insertion (Patient 10). When the the ROTEM parameters were examined, this patient had lowest CT and highest AA in EXTEM, and the highest AA in INTEM, indicating more pro-coagulant status (Table 1). Also patient 14 had similar AA as patient 10 in EXTEM and INTEM but was not found to develop thrombosis by the 18th day of insertion. However, CVC of that patient wasn't removed yet

Table 1.

Patient n°	Thrombosis	EXTEM CT (38-79)*	EXTEM CFT (34-159)	EXTEM MCF (50-72)	EXTEM AA (63-83)	INTEM CT (100-240)	INTEM CFT (50-110)	INTEM MCF (50-72)	INTEM AA (70-83)	FIBTEM CT (38-62)	FIBTEM CFT *	FIBTEM MCF (9-25)	FIBTEM AAF
1	No	64	50	71	82	135	70	82	86	64	26	26	82
2	No	59	73	78	84	143	64	69	77	73	112	24	76
3	No	73	154	53	56	158	112	57	69	65	-	6	-
4	No	63	132	69	80	159	57	61	82	67	167	28	81
5	No	60	51	71	82	115	51	72	80	51	350	24	81
6	No	74	69	66	77	199	77	65	75	85	-	11	-
7	No	69	923	23	45	88	215	35	79	59	-	9	-
8	No	57	84	68	81	148	78	76	84	69	266	39	83
11	No	77.00	129.00	33.00	66.00	108	51.00	69.00	81.00	66.00	-	5.00	-
12	No	58	69	71	82	134.00	68	71	80	51	-	18	80
13	No	54	147	58	63	160	89	61	73	62	-	7	77
14	No	43	18	86	87	69	29	81	84	50	41	35	88

*CT; clotting time, CFT; clot formation time, MCF; maximum clot firmness, AA; alpha angle, * Normal range, & INTEM couldn't be measured for patient 1 due to technical reasons, β In some patients CFT and/or AA weren't in measurable level*

Summary/Conclusions: In this study we reported our preliminary results. We detected thrombosis only in one patient and according to this limited samples size, we may suggest that CT and AA in EXTEM, and AA in INTEM prior to insertion of CVC may be predictive for catheter related thrombosis development. Such patients with pro-coagulant findings at ROTEM prior to CVC insertion may need prophylactic anti-coagulation. The results in a larger sample size will be more definitive to make a conclusion.

E1604

THE POTENCIAL ROLE OF ANTINEOPLASTIC DRUGS IN THE PREDICTION OF THROMBOTIC RISK IN ONCOLOGIC PATIENTS IN ADDITION TO THE KHORANA SCORE

E. Gómez[1,*], P. García-Ramírez[1], A. Zabalza[1], M. Montoya[1], M. Alvarellos[1], D.P. Millacoy[1], B. Signes[1], T. Galicia[1], M.V. Aznar[1], A.M. Redondo[1], M.J. Paloma[1], M.L. Antelo[1]
[1]Hematology, Complejo Hospitalario de Navarra, Pamplona, Spain

Background: Venous thromboembolism (VTE) is common in patients with cancer. Several risk factors (related with patient, tumour and treatment) have been already identified. Thromboprophylaxis (TP) with low molecular weight heparin (LMWH) is associated with a reduction of symptomatic VTE but without clear benefit in survival as the number of major bleedings is increased. To guide primary TP in newly diagnosed cancer outpatients starting chemotherapy (QT), a risk assessment model (based in baseline clinical and laboratory variables) was developed (the Khorana score). Many patients with intermediate risk (without tromboprophylaxis indication according to Khorana-based clinical guidelines) develop VTE episodes. Factors as tissue factor-bearing micro particles and D-Dimmer levels in addition to lenalidomide, platin and gencitabine-based therapies are associated with VTE high risk. Its efficacy as a predictive tool is a matter of debate.
Aims: This retrospective, observational study is aimed to assess the Khorana score efficacy in predicting the VTE risk and analyze some treatment related factors as predictive complementary tools.
Methods: We analyzed the demographic characteristic, the Khorana score and the antineoplastic treatment of oncologic patients diagnosed of pulmonary embolism (PE) from December 2010 until December 2016 at the Complejo Hospitalario de Navarra. At baseline, the Khorana score classified patients as 'low risk' (0 points) intermediate risk' (1-2 points) or 'high risk' (≥3 points) for VTE.
Results: 102 oncologic patients were diagnosed of PE. Patient baseline characteristics are showed in table 1. In 27.5% (n=28) PE diagnosis preceded to cancer diagnosis, in 26.5% (n=27) PE occurred at least 1 month beyond the end of antineoplastic treatment and in 46.1% (n=47) PE was diagnosed during the treatment (chemotherapy +/- radiotherapy). In this last group the median time from the treatment beginning and EP diagnosis was 3 months (0-46). The stratification according to the Khorana score (at baseline) was: 'low risk' 21.3%, intermediate risk 61.7%, and high risk 17%. In the intermediate risk group (n=29) the drug-based therapy was: 44.8% platin (n=13), 6.9% gemcitabine (n=2), 2.5% lenalidomide (n=1) and 48.3% non-related-thromboembolic treatment (n=14). Most of cases (97.1%) were managed with LMWH (enoxaparin 1mg/kg/twice a day). Only 2 patients were treated with non-fractionated heparin and 1, enrolled in a clinical trial, was treated with direct oral anticoagulants.

Table 1.

Table1. Baseline patient characteristic

	n=102 (%)
Sex, male (%)	69 (67.6%)
Age, median (range)	66 (28-93)
Cancer localization	
Lung	27 (26.5%)
Colorectal	19 (18.6%)
Genitourinary	18 (17.7%)
Breast	9 (8.8%)
Pancreas	4 (3.9%)
Gastric	4 (3.9%)
Gynecological	6 (5.9%)
CNS	4 (3.9%)
Hematologic	4 (3.9%)
Esophagus	1 (1%)
Others	6 (5.9%)
Metastasis	54 (52.9%)
Incidental	40 (39.2%)
Ambulatory	80 (78.4%)

Summary/Conclusions: Nearly 2/3 of Khorana intermediate risk patients developed a PE while on antineoplastic treatment and inside this group over 50% were treated with well-recognized high thrombotic-risk drugs. The inclusion of antineoplastic drugs in a predictive thromboembolic model in oncologic patients could improve the benefit-risk of the use of LMWH prophylaxis in some patients without a high risk Khorana score but however at high risk of thrombosis. More prospective studies are needed to analyse the benefit of antithrombotic prophylaxis in oncologic patients receiving outpatient chemotherapy treatment.

Transfusion medicine

E1605

CLINICAL OUTCOMES AND UTILIZATION OF BLOOD BANK RESOURCES OF PATIENTS WITH THROMBOTIC THROMBOCYTOPENIC PURPURA (TTP), HEMOLYTIC UREMIC SYNDROME (HUS), AND OTHER MICROANGIOPATHY- A 14 YEARS' EXPERIENCE

C.-T. Lee[1,2,*], C. Thow[3], K.P. Lim[3], S.T. Lim[3], J. Mah[3], N.N. Zhang[3], M.L. Tung[1], L.K. Tan[1,3], S.Y. Lee[1,2,3]
[1]Department of Haematology-Oncology, National University Cancer Institute Singapore, [2]Yong Loo Lin School of Medicine, National University Singapore, [3]Blood Transfusion Service and Blood Donation Centre, Department of Laboratory Medicine, National University Hospital, Singapore, Singapore

Background: TTP, HUS and other thrombotic microangiopathy are rare, complex clinical syndromes which are characterized by thrombocytopenia, microangiopathic haemolytic anemia, (MAHA) and systemic thrombosis. The introduction of plasma exchange (PEX) had dramatically reduced the mortality of these patients, and has become standard of treatment. Although the clinical outcome of these conditions is heterogenous, with multiple clinical complications and prolonged hospital stay, there is no previously published data to provide measurement of blood bank and hospital resource utilization associated with its clinical management.
Aims: We performed a retrospective cohort study of 42 consecutively treated patients with MAHA and analyzed their clinical and laboratory characteristics, treatment outcomes and plasma product utilization.
Methods: Medical records of these patients treated from 2002-2017 were reviewed. We used the standardized criteria based on the consensus on standardization of terminology in TTP to define clinical response. (Scully et al J Thromb Haemost 2017).
Results: Results: In our series, the causes and number (%) of MAHA were TTP-HUS (18, 42.9%), autoimmune disorder-associated MAHA (13, 31% *i.e.* 9 SLE and 4 Sjögren's syndrome), cancer-related MAHA (4, 9.5%), drug-induced (3, 7.1%), post-transplant and infection-related microangiopathy (4, 9.5%). The average number of PEX sessions required to achieve overall clinical response in TTP, autoimmune-associated MAHA, HUS and drug-induced microangiopathy was 18.2±17.9, 11.5±7.6, 13.0±8.7 and 7.3±6.7, respectively. The mean follow up time was 40.8 months. 5 patients (11.6%) died during the course of treatment in index hospitalization, 12 (27.9%) were refractory to PEX and 24 patients (55.8%) responded to PEX, and 1 patient was lost to follow up. 1 patient relapsed 8 months after achieving clinical remission and was successfully treated with Vincristine. Another patient developed exacerbation and was palliated eventually. For the refractory cases, 7 patients were given Rituximab, 5 achieved clinical response while those who were given Vincristine (n=3) and Cyclophosphamide (n=2), achieved clinical response with a median of 15 days from the time second line agents were used. The 1 year overall survival of those who received second line treatment compared to patients who responded to only PEX and standard of care was 59% and 80% (p=0.51), respectively. The overall 1 year survival of the entire cohort is 74% which is comparable to the Oklahoma registry. The mean length of hospital stay was 30 days (median 27 days, SD±20.2). Complications encountered during PEX included bleeding (9.5%), seizures (11.9%), cardiovascular complications like myocardial infarction and stroke (16.7%), and nosocomial infection (16.7%). 30% of the cohort required temporary dialysis support for acute kidney injury while 38% of them ended up required lifelong dialysis. With regards to the cost of plasma units, consumables and PEX procedure, the calculated mean cost was Singapore Dollar (SGD) 25252.95 (€16991.17) (SD±20859.41 (€14035.02)) per patient.
Summary/Conclusions: The clinical outcome in terms of survival in our cohort is in keeping with that of other registry and cohort (Hovinga et al Blood 2010). Our data which demonstrate the health care resource utilization show that management of these patients is expensive. While small in terms of incidence, it poses an economic burden disproportionate to its overall size.

E1606

HEPATITIS E VIRUS: INVESTIGATION IN NORTH ITALIAN BLOOD DONORS

L. Raffaele[1,*], M. Spreafico[1], B. Foglieni[1], I. Guarnori[1], S. Brambilla[1], S. Fumagalli[1], D. Prati[1]
[1]Transfusion Medicine and Hematology, ASST-Lecco, Lecco, Italy

Background: Hepatitis E virus (HEV) is a major cause of acute hepatitis worldwide, and a possible threat to transfusion safety. Recent data from Europe showed a HEV IgG prevalences of 6.8% in German blood donors, 27% in Dutch blood donors, and 52% in an hyperendemic area in the South of France.
Aims: The aim of this study was to determine the prevalence of anti-HEV reactivity and HEV viremia in Italian blood donors, in order to estimate the risk of transfusion transmission.
Methods: Nearly 10,000 samples were collected from anonymized, unpaid donors at the "Lecco processing and validation blood center" (Lombardy, Italy) from June to July 2016. Samples were tested individually (individual-donation nucleic acid test [ID-NAT]) for HEV RNA using the Procleix HEV assay (95% limit of detection 7.9 IU/mL). Initial TMA-reactive samples were retested and considered positive if the retest result was reactive. For the serology study, a subset of 2000 donations was tested for HEV IgG using DiaPro HEV ELISA kit (Diagnostic BioprobesSrl, Milano, Italy). HEV IgG and IgM were analyzed in ID-NAT positive samples at the time of donation and in the follow up, collected one year after the index donation.
Results: The prevalence of IgG anti-HEV in north Italian blood donors was 7.4%. Nine out of 9,726 donor samples gave reactive values by the ID-NAT assay for HEV RNA. Among them, only one sample was confirmed to be reactive in additional TMA tests. None of the 9 HEV RNA initially reactive samples had circulating IgM or IgG antibodies against HEV. In the follow up, only the repetitive reactive donor shewed a IgM and IgG seroconversion, indicating primary HEV infection. Therefore, we estimated that the risk of receiving a potentially infectious blood unit is of 1:10.000 (upper bound of the 95% confidence interval, 1:1700).
Summary/Conclusions: Anti-HEV reactivity, indicating a previous infection, was found in 7.4% of subjects admitted to blood donation in our area. We also identified a viremic blood donation, indicating that the risk of transmitting the infection through blood transfusion, although small, is not negligible. The clinical impact of HEV infection among blood recipients remains to be assessed. These data need to be considered when deciding a national policy for preventing HEV transmission.

E1607

SHORT-TERM ADMINISTRATION OF RECOMBINANT HUMAN ERYTHROPOIETIN DECREASES B CELL IN HUMAN PERIPHERAL BLOOD

T. Nagashima[1,*], A. Yokohama[2], M. Awata[1], Y. Kanai[1], K. Murata[1], R. Ino[1], Y. Kitamura[1], K. Honma[1], N. Gotoh[1], T. Kasamatsu[1], H. Handa[3], T. Saitoh[1], H. Murakami[1]
[1]Department of Laboratory Sciences, Gunma University Graduate School of Health Sciences, [2]Blood Transfusion Service, [3]Department of Hematology, Gunma University Hospital, Maebashi, Gunma, Japan

Background: Erythropoietin (EPO) is hematopoietic factors participating in red blood cell production, and accelerates proliferation and inhibits apoptosis of erythroblasts. It is reported that EPO has pleiotropic effects including anti-apoptotic action for some cells, antioxidant action, vascularization action, and promoting cell division in addition to stimulation of erythropoiesis as well, whereas there are conflicting results of small cohorts as to its effect on blood immune cells.
Aims: We analyzed peripheral white blood cell subsets in patients who received one bolus administration of recombinant human erythropoietin (rHuEPO) to examine the effect of EPO on human immune system.
Methods: One hundred nineteen autologous blood donors (male/female 62/57) in Gunma University Hospital were enrolled in this study after written informed consent. All the patients had no infections or inflammation. Forty nine patients were treated with rHuEPO (Epoetin alpha or Epoetin beta (24,000 IU, respectively)) once after blood donation because of low hemoglobin concentration and 70 were not treated. Peripheral blood samples were obtained at the time of the first phlebotomy and after 1week from the same patient.We measured the number of WBC, lymphocytes, myeloid dendritic cells (mDC), plasmacytoid dendritic cells (pDC), CD4+ T cells, CD8+ T cells, Natural killer (NK) cells, B cells, monocytes, and neutrophils of peripheral blood before and after rHuEPO administration by flow cytometry. Also we compared treatment group with non treatment group. Paired and unpaired Student's t-test were used to compare absolute counts and percentages of each cell, P values<0.05 were considered significant. This study was approved by the research ethics committee of our hospital.
Results: In treatment group, absolute number and percentage of lymphocyte in WBC decreased significantly after rHuEPO administration from 1985.0±520.8/μl to 1798.7±439.0 /μl, in absolute number (p=0.019), and from 33.2±8.57% to 30.0±7.32% in percentage (p=0.023). The numbers of whole WBC, mDC, pDC, monocyte and neutrophil did not change significantly. In respect of lymphocyte subsets, absolute number of CD8+ T cell, NK cell and B cell significantly decreased from 358.9±257.0 /μl to 311.5±210.9/μl (p=0.04), from 290.6±157.6 /μl to 257.4±141.8 /μl (p<0.01) and from 289.3±192.4 /μl to 239.9±158.2 /μl (p<0.01), respectively. Regarding B cell subsets, absolute number of naïve B cell and IgD^{-} $CD27^{-}$ B cell significantly decreased from 171.3±93.5 /μl to 153.0±84.2 /μl (p<0.01), and from 16.5±13.6 /μl to 12.9±12.7 /μl (p=0.045), respectively. Moreover, other B cell subsets, such as transitional B cells, memory B cells and marginal zone B cells, also showed a trend of decrease. However, percentages of naïve B cell and $IgD^{-}CD27^{-}$ B cell in total B cell did not change. These suggested that whole B cell decreased, not a specific subset of B cell. In non treatment group, there was no significant change in any type of immune cell.
Summary/Conclusions: These findings suggested that just one administration of rHuEPO influenced human immune system, especially via reduction of B cell in peripheral blood, with unknown mechanism so far.

E1608

BLOODLESS TREATMENT OF HEMATOLOGIC MALIGNANCIES AND APLASTIC ANEMIA - JEHOVAH'S WITNESSES (JW)

K. Kim[1,*], M.-Y. Lee[1], N.-S. Lee[1], J.-H. Won[1], J. Yoon[2], S.H. Kim[2], C.-K. Kim[2], H.J. Kim[3], S.-C. Lee[3], S.B. Bae[3], K.T. Lee[3], S.K. Park[2], D.S. Hong[2]

[1]Internal Medicine, Soonchunhyang University Hospital, Seoul, Seoul, [2]Internal Medicine, Soonchunhyang University Hospital, Bucheon, Bucheon, [3]Internal Medicine, Soonchunhyang University Hospital, Cheonan, Cheonan, Korea, Republic Of

Background: At most centers, the majority of patients who request bloodless medicine are members of the Jehova's Witness (JW) faith. But, there are no standard, established guidelines to manage pancytopenia in these patients, nor are there many studies to inform optimal treatment approaches. The most troublesome patients who request bloodless medicines are patients with hematologic malignancy. The treatments of these patients are considerable challenges. They have not only problems of severe pancytopenia, but also require intensive chemotherapy. Since 2000, our hospital has been a bloodless center. This study was retrospectively analyzed for hematologic malignancies and aplastic anemia with bloodless treatments in Soonchunhyang university hospital.
Aims: This study was retrospectively analyzed for hematologic malignancies and aplastic anemia with bloodless treatments in Soonchunhyang university hospital.
Methods: A retrospective review of medical records was performed of 44 patients with hematologic malignancies and aplastic anemia who request bloodless medicine from January 2006 to December 2015 at Soonchunhyang university hospital.
Results: Of 44 patients, 48% were men (n=21) and 52% were women (n=23). The median age of the study population at the time of diagnosis was 62 years (range 16-87). Thirteen patients (29.5%) were acute leukemia, 15 (34.1%) patients with non-Hodgkin's lymphoma (NHL), 2 (4.5%) patients with aplastic anemia (AA), 6 (13.6%) patients with chronic myeloid leukemia (CML), 4 (9%) patients with myelodysplastic syndrome (MDS) and 4 (9%) patients with multiple myeloma (MM). Thirty one patients were treated with chemotherapies and 13 patients were treated with supportive care only. Among 44 patients 27 patients were died. Most common cause of attribution to death was anemia (92.5%). And Chief complaint at death was dyspnea (88%). Median survival of acute leukemia was 1 month (95% CI, 0.41-1.59).

Table 1.

Acute leukemia (15 patients)

Gender	Age	Diagnosis	Regimen	Chemotherapies	Response	Survival	death
F	87	Acute leukemia		no		0.0	death
M	84	Acute leukemia		no		1.2	death
F	81	Acute leukemia		no		0.7	death
M	16	ALL		no		3.9	death
M	17	ALL	R-CHOP	yes	refractory	4.4	death
F	81	AML		no		1.0	death
M	81	AML		no		1.4	death
M	40	AML	low dose Ara-C	yes	refractory	1.0	death
M	74	AML	hydroxyurea	yes	refractory	0.7	death
48	F	AML	Ara-C/Idarubicin	yes	refractory	0.6	death
70	F	AML	mFLAI → CR1 (induction#1,consol #2)	yes	CR	16.5	death
51	F	APL	ATRA	yes	refractory	0.3	death
47	M	APL	ATRA → CR1 Relapse ATO → CR2	yes	CR	34.7	alive

Summary/Conclusions: In bloodless treatment, CML, MM and lymphoma had a relatively good prognosis. However, AML and MDS were showed a poor prognosis. Therefore, further studies are needed to improve survival for bloodless patients with hematologic malignancies.

E1609

PREOPERATIVE ANEMIA: A SINGLE INSTITUTION EXPERIENCE IN SPAIN

G. Pinto[1,*], F. Ruiz[1], I. Page[1], G. Yumi[1], G. Moreno[1]
[1]Hematology, Hospital Ramon y Cajal, Madrid, Spain

Background: Preoperative anemia is considered as a strong predictor of postoperative red cell transfusions, and has also been linked to increased morbidity and mortality in surgical patients, but it is frequently overlooked.
Aims: The objective of this study is measure of real impact of preoperative hematological assesment and optimization of anemic patients in terms of decreasing blood cells transfusions.
Methods: We analyzed 85 patients undergoing elective surgery in subgroups of high or low risk of bleeding. All the patients were referred from pre-anesthesia consultation for performing a 4-week hematological protocol in order to optimize the hemoglobin level to a near normal value. We identified the underlying cause of anemia and offered the treatment according to the etiology. The primary outcomes were the response to therapy defined as reaching the Hb level >13 gr/dL or increasing of >2 gr/dL from basal level, and the rate of blood transfusion.
Results: Mean age was 70.4 years, with a male-female ratio of 1:2, and the patients were divided into 2 groups according to the bleeding risk: high risk 74% (hip and knee replacement, cystectomy, colectomy, maxilofacial surgery), and low risk 26% (mastectomy, gynecology or spine surgery), with a median hemoglobin of 10,9% and 10,1%, respectively. A diagnostic workup was performed in order to provide appropiate treatment: iron deficiency anemia (83,9%), anemia of chronic disease (10,3%), folate or vitamin B12 deficiency (5,8%). The patients with iron deficiency anemia received oral (62%) or intravenous iron (38%), but third of patients had to change from oral to intravenous iron by intolerance or poor response. The response to treatment was reached by 44.7% of patients, in an average time of 26,4 days. The rate of blood transfusion was 18% in good responders (0,5 packed red blood cells per patient) and 63% in poor responders (1,6 packed red blood cells per patient).
Summary/Conclusions: Treatment strategies over preoperative period, and the effort to reach a near to normal hemoglobin level, could minimize the amount of red blood cell transfusion the patients will be exposed in the postoperative period. Our data provide evidence about the effectiveness of a prompt evaluation and correction of preoperative anemia in a maximum time of 4 weeks.

E1610

RED BLOOD CELLS (RBC) AND PLATELET (PLT) TRANSFUSIONS IN TRANSPLANTED AND NOT-TRANSPLANTED PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

E. Baldoumi[1], V. Papadopoulos[2], V. Kalaitzidou[1], A. Syrigou[1], C. Lalayanni[1], M. Papathanasiou[1], D. Mallouri[1], C. Smias[1], I. Sakellari[1], A. Anagnostopoulos[1], D. Sotiropoulos[1,*]
[1]Haematology Department & BMT Unit, George Papanicolaou Hospital, [2]Hematology Department, Papageorgiou General Hospital, Thessaloniki, Greece

Background: Patients with hematological malignancies require often and prolonged hospitalisations during the course of their treatment, in part due to increased and frequent transfusion demands.
Aims: The objective of the study was to assess the factors affecting transfusion needs in a Hematology Department (bone marrow transplant unit- BMTU, post-transplant unit-PTU, hematology clinic).
Methods: The patients that were hospitalized between 1/1/2015 and 31/12/2015 were analyzed. Data regarding the underlying disease, the disease status, type of transplant, duration of marrow aplasia and donor-patient blood group mismatch were obtained from the medical records. The analysis was restricted to the transfusion of packed RBCs and units. Differences between groups were assessed using non-parametric statistics (Kruskall-Wallis and Mann-Whitney U-test).
Results: There were 523 admissions of 256 different patients. Complete data for analysis could be obtained for 487 admissions of 237 patients (92.6% of patients, 93.1% of admissions), corresponding to 10,673 days of hospitalization. Total number of blood products transfused was 2284 packed RBC units, 13883 PLT units (apheresis platelets counted as 5 units). Values are reported as median (range), unless otherwise specified. In the BMTU, the type of transplant was correlated with transfusion needs: number of RBC units transfused per admission was 2 (1-5) for autologous transplanted (AUTO) patients, 4 (1-28) for allo-transplanted (ALLO) (no difference between sibling and matched unrelated donors), and 7 (1-14) for haplo-identical transplantations (HAPLO), p=0.001. Platelet units requirements were respectively 15 (5-45) for AUTO, 20 (5-205) for ALLO and 50 (30-130) for HAPLO, p<0.001. The length of stay was 18 (13-23) days in AUTO, 22 (16-44) in ALLO, 30 (29-40) days in HAPLO transplantation, p<0.001, while the duration of aplasia in days was 9 (4-19) in AUTO, 13 (5-32) in ALLO and 25 (20-38) in HAPLO, p<0.001. The longer duration of aplasia and hospitalization was correlated with greater transfusion needs. In the PTU there was no statistically significant difference in transfused RBC or PLT units with regard to transplant type. Disease status (response *versus* active disease) was only correlated with RBC units transfused in PTU [2 (1-29) *vs* 6 (1-56) units respectively, p=0.006]. Donor – patient blood group mismatch was correlated with increased transfusion demands in BMTU for RBCs [4 (1-28) *vs* 2 (1-5), p<0.001] and PLTs [25 *vs* 15, p<0.001]. In hematology clinic, the underlying disease was correlated with transfusion needs in RBC and PLTs, as shown in table 1. Patients with AML had the higher needs in RBCs and PLTs, whereas patients with lymphoma had the lowest needs in RBC transfusions. Disease status was not correlated with transfusion needs. The duration of aplasia was correlated with the number of RBC units (Pearson's r=0.66, p<0.001, r^2=0.435) and of PLTs transfused (Pearson's r=0.78, p<0.001, r^2=0.61).

Table 1. Units transfused in hematology clinic

	ALL	AML	Lymphoma	MPN	Myeloma	MDS/AA	
RBCs	3 (0-7)	5 (0-30)	2 (0-45)	5 (0-10)	3 (0-8)	3 (0-15)	p<0.001
PLTs	10(0-70)	30(0-250)	5 (0-240)	20(0-55)	10(0-60)	0(0-180)	p<0.001

Summary/Conclusions: The main determinants of transfusion requirements are the duration of aplasia, the type of transplant and the disease, with myeloid malignancies requiring more transfusions. The establishment of haplo-identical transplantations has increased the transfusion needs due to longer period of aplasia.

BOTANICAL ALKYL HYDROQUINONE HQ17(3) EXERTS CYTOTOXICITY TO T(9;22) PHILADELPHIA CHROMOSOME SUP-B15 ALL CELLS THROUGH INDUCING ENDOPLASMIC RETICULUM STRESS, AUTOPHAGY, AND AIF TRANSLOCATION

C.-W. Chen[1], Y.-J. Chang[1], Y.-Y. Kuo[2], L.-I. Lin[1], C.-Y. Hu[1,*]
[1]Department of Clinical Laboratory Sciences and Medical Biotechnology, [2]Graduate Institute of Oncology, College of Medicine, National Taiwan University, Taipei, Taiwan, Republic of China

Background: Patients suffering from Acute lymphoblastic leukemias (ALLs) harboring t(9;22) genetic abnormality are classified very high risk (VHR) ALLs displaying poor clinical outcome irrespective of intensive chemotherapies and tyrosine kinase inhibitor treatment. Development of new adjuvant therapeutics will provide great value. HQ17(3)[10'(Z),13'(E),15'(E)-heptadecatrienyl hydroquinone] isolated from sap of the lacquer tree showed potent cytotoxic effect within 24 hours at micromolar concentration on several ALL cell lines, including TKI (Imatinib, IM)-refractory Ph$^+$ B-ALL cell line SUP-B15 cells, but spare normal PB leukocytes, and were non-toxic in experimental rats after 28-day HQ17(3) injection. Thus HQ17(3) presents as a potential anti-leukemic agent and serves a model for design anti-leukemic regimen. We previously showed HQ17(3)-induced rapid cell demise, characterized by oxidative stress, loss of membrane integrity, mitochondrial membrane potential disturbance and nuclear DNA fragmentation. Neither pan-caspase inhibitor nor Nec-1 (RIP-1 inhihitor) protected SUP-B15 cells from HQ17(3)-induced cell death. The cell death program elicited by HQ17(3) is caspase-independent, and is different from the RIP1-mediated controlled necroptosis.
Aims: To investigate the characters of, and the molecular pathways involved in the HQ17(3)-induced non-classical death on VHR-ALL SUP-B15 cells and help developing effective therapeutic strategies for the VHR-ALLs.
Methods: Cell growth inhibition in response to HQ17(3) w/wo inhibitors was analyzed by ACP assay. Cells were stained by Annexin V/PI and analyzed by flow cytometry for cell death. Lysosomal protease inhibitors (AEBSF (serine protease inh.), pepstatin/CA074-Me (cathepsin D/B inh.)) or autophagy inhibitors (Bafilomycin A1) were used in combination with HQ17(3) in some experiments. Acridine orange stain and confocal microscopy are used to visualize the changes of acidic vesicles. Autophagic flow in response to HQ17(3) was revealed by aggregation of ectopically expressed EGFP-LC3. Western blot analysis were used to analyze p- eIF2a, ER chaperone Grp78, spliced XBP-1 (markers for ER stress). Lenti-viral delivery of shRNAs was used to repress the expression of Beclin-1. Nuclear accumulation of apoptosis inducing factor (AIF) was revealed by fluorescence microscopy.
Results: Enlarged acidic vesicles accumulated soon after HQ17(3) treatment, and deminished when cell death ensued. HQ17(3)-induced cell death could not be attributed to cathepsins released from lysosomal membrane permeabilization (LMP) as cathepsin inhibitors did not attenuate the cell death. HQ17(3) enhanced autophagy as revealed by aggregation of ectopically expressed EGFP-LC3. Inhibition of autophagy by Bafilomycin A1 or knockdown the essential autophagy-related Beclin1 by shRNA could partially attenuate HQ17(3)-induced cell death. Further, HQ17(3) treatment gave rise to early ER stress as revealed by enhancement of eIF2a phosphorylation and up-regulation of ER chaperone Grp78. HQ17(3) induced nuclear translocation of AIF, in compatible with mitochondria disturbance and caspase-independent cell death thereafter.
Summary/Conclusions: In Ph$^+$-ALL SUP-B15 cells, HQ17(3) acts in multifacet: a) lead to oxidative stress and perturb mitochondria membrane integrity, b) induce ER stress and calcium mobilization to mitochondria, cleave and release AIF to mediate nuclear chromatin cleavage, c) HQ17(3)-induced autophagy may be implicated cell death. This study shows agents that are capable of eliciting an intricate effector network in therapy-induced cytotoxicity will have potential as adjuvants controlling the VHR-Ph$^+$-ALL cells refractory to conventional high dose chemotherapies and TKI regime.

TARGETED MUTATIONAL PROFILING OF CHILDHOOD AND ADULT ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS

J. Peric[1], T. Karan Djurasevic[1], T. Kostic[1], I. Marjanovic[1], J. Lazic[2], M. Virijevic[3], N. Krstovski[2,4], L. Dokmanovic[2,4], D. Tomin[3,4], A. Vidovic[3,4], N. Suvajdzic Vukovic[3,4], D. Janic[2,4], S. Pavlovic[5], N. Tosic[1,*]
[1]Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, [2]University Children's Hospital, [3]Clinic of Hematology Clinical Centre of Serbia, [4]School of Medicine University of Belgrade, [5]Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, Belgrade, Serbia

Background: Acute lymphoblastic leukemia (ALL) is the most common cancer in children, representing about 80% of acute leukemias, whereas it is less common in adults (20%). Identification of cytogenetic aberrations and a small number of molecular abnormalities are still the most important risk and therapy stratification methods in clinical practice today.
Aims: The aim of the present study was to assess mutational profile of both childhood (cALL) and adult acute lymphoblast leukemia (aALL) patients, by applying targeted next generation sequencing (NGS) on MiSeq System.
Methods: We analyzed DNA samples from 34 de novo ALL patients (17 cALL and 17 aALL) using TruSeq Amplicon – Cancer Panel (TSACP) that targets mutational hotspots in 48 cancer related genes (212 amplicons). The bioinformatics analyses was conducted using processing pipeline composed of both freely available open source bioinformatics tools as well as tools developed in-house. The average coverage of high-quality sequences was 2609 × per amplicon. Ten genes were discarded due to insufficient coverage, therefore we analyzed a total of 183 amplicons from 38 genes. Variants were identified in relation to the GRCh37 reference genome by applying a Bayesian approach and compared to public genetic variation databases and in-house databases.
Results: We identified a total of 331 (159 cALL, 172 aALL) variants in the coding regions (median per patient: 9, range: 6-12; median per cALL: 9, range: 6-12; median per aALL: 10, range: 7-12) and 429 (211 cALL, 218 aALL) variants in the non-coding regions (median per patient: 13 range: 10-15; median per cALL: 13, range: 10-14; median per aALL: 13, range: 10-15**)**. Overall, a total of 98 variants (median per patient: 2.8, range: 1–6) were potentially protein-changing, including nonsense, frameshift, and missense (NFM) mutations. There were no significant differences in the number of NFM mutations between cALL (total 47, median per patient: 3, range: 1–5) and aALL patients (total 51, median per patient: 3, range: 1–5). Moreover, we identified 5 NFM mutations in *STK11* gene, 3 in *ABL1*, *RET, KRAS* and 2 in *HNF1A, NRAS,* and *NOTCH1.* Observed in individual patients detected mutations predominantly disrupted Ras/RTK pathway (*STK11*, *KIT*, *MET*, *NRAS*, *KRAS*, *PTEN*). Additionally, we identified 5 patients with the same mutation in *HNF1A* gene coding for transcriptional factor, disrupting both Wnt and Notch signaling pathway. Notch pathway was disrupted in two patients in which detected variants affected *NOTCH1* gene. *HNF1A* and *NOTCH1* variants were mutually exclusive, while genes involved in Ras/RTK pathway exhibit a tendency of mutation accumulation.
Summary/Conclusions: Our targeted NGS study showed low number of recurrent mutations in both cALL and aALL patients. Detected mutations affect few key signaling pathways, primarily Ras/RTK and Notch pathways. This study contributes to knowledge of ALL mutational landscape, leading to better understanding of molecular basis of ALL and better stratification and treatment of ALL patients.

PB1613

RELAPSED LOW HYPODIPLOID ACUTE LYMPHOBLASTIC LEUKAEMIA IN A LI-FRAUMENI PATIENT

F. Van Delft[1,2,*], G. Cuthbert[3], K. Robinson[3], S. Bailey[2], R. Skinner[2], G. Shenton[2]
[1]Northern Institute for Cancer Research, Newcastle University, [2]Children and Adolescent Haematology and Oncology , Great North Children's Hospital, [3]Northern Genetics Service, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom

Background: A 7-year old girl presented with backache, leg pain and difficulty walking. She was referred to the local paediatric oncology service, as she was known with Li-Fraumeni Syndrome (LFS). Cancers linked to this disorder include soft tissue sarcomas, osteosarcoma, breast cancer, brain cancer, leukaemia and adrenocortical carcinoma. The patient's mother had breast cancer twice, and both her (monozygotic) twin sister and older sister had adrenal cortical carcinomas removed. The patient was born with left sided twinning defects (absent left kidney, malrotation, absent left ear and ear canal, Arnold-Chiari malformation with spinal cord syrinx and hydrocephalus). At presentation there was a suspicion of a disseminated malignancy. She underwent an MRI scan which showed extensive changes in her spinal column and hips. Bone marrow biopsy revealed Acute Lymphoblastic Leukaemia (ALL). Paucity of diagnostic material restricted the cytogenetic analyses. G-banding showed 46,XX[14], with FISH demonstrating loss of FOXO1/13q14.11 [44%], gain of MYC/8q24.21 [9%], ETV6-RUNX1 NEGATIVE, gain of RUNX1/21q22.12 [21%] and BCR-ABL1 NEGATIVE. The patient was treated according to NCRI risk criteria on the least intensive regimen of the UK ALL 2003 trial. She achieved morphological remission after a 3-drug induction, and successfully completed further treatment, including intensification/CNS directed phase, interim maintenance and 2 delayed intensification blocks. She completed 5 years of follow-up and was transferred to the Long Term Follow-Up Clinic, when she presented with hypercalcaemia. Peripheral blood and bone marrow biopsy confirmed a diagnosis of ALL. Although the phenotype resembled the profile of the first presentation of leukaemia, the genetic aberrations appeared incongruent.
Aims: Establish the origin of the second episode of ALL in a patient with known Li-Fraumeni Syndrome. As treatment and outcome for relapsed ALL in comparison with a second, primary, ALL are completely different, this information was critical to guide further management.
Methods: We set out to comprehensively characterise the second ALL, including conventional G-banding and fluorescence *in situ* hybridisation (FISH). The

acquired results were compared with those derived from the first ALL diagnosis.
Results: The G-banding analysis showed 36,XX,-2,-3,-4,del(5)(q31q35),-7,-12,-13,-14,-15,-16,-17[13]/46,XX[7]. Extensive FISH analysis confirmed the diagnosis of low hypodiploidy ALL. This result was in line with the reported association between *TP53* gene mutations in 90% of cases of low hypodiploid ALL, with these mutations often present in normal cells. [Holmfeldt, Nat Gen, 2013] At first sight, this did not recapitulate the original cytogenetic analysis and suggested the occurrence of a second episode of ALL. In order to further characterise the diagnostic genetics, FISH probes were used on archived diagnostic slides. Careful selection of probes demonstrated that the original leukaemia sample contained two co-existing clones – one low hypodiploid clone (with an identical pattern of loss and gain of chromosomes as the second ALL) and one clone resembling a doubled up/near triploid low hypodiploid clone.
Summary/Conclusions: This case report demonstrates the value of in-depth genetic analyses to guide management of patients with ALL. This patient proceeded with re-induction according to our current relapsed therapy guidelines (R3), to which she has shown a promising response. She is considered for allogeneic bone marrow transplantation using an unrelated donor.
In hindsight, the treatment regimen used for the initial ALL was incorrect. If it had been established that she had low hypodiploid ALL the first time around, she would have been allocated the most intensive regimen within the trial. Nevertheless, she maintained remission status for 5 years with low intensity treatment and ironically relapsed when most patients are told they are cured.
Since the original diagnosis of ALL in 2007, research has vastly improved our understanding of the biology and genetic landscape of ALL. This has facilitated risk stratification, improved outcome after treatment and identified novel drug targets. Genomic profiling of low hypodiploid ALL has identified oncogenic activation of Ras and phosphoinositide 3-kinase (PI3K) signalling conferring sensitivity to PI3K inhibitors, thus providing therapeutic avenues if conventional treatment were to fail.

PB1614

IMMUNOLOGICAL CHARACTERIZATION OF PH+ ALL BONE MARROW BY MULTIPLEX IMMUNOHISTOCHEMISTRY

H. Hohtari[1,*], O. Brück[1], S. Blom[2], R. Turkki[2], A. Ribeiro[2], M. Sinisalo[3], P. Kovanen[4], O. Kallioniemi[2], T. Pellinen[2], K. Porkka[5], S. Mustjoki[1]
[1]Hematology Research Unit, University of Helsinki and Helsinki University Central Hospital Comprehensive Cancer Center, [2]Institute for Molecular Medicine Finland (FIMM), Helsinki, [3]Division of Hematology, Tampere University Hospital, Tampere, [4]Department of Pathology, HUSLAB and Haartman Institute, Helsinki University Central Hospital and University of Helsinki, [5]Hematology Research Unit, University of Helsinki and Helsinki University Central Hospital Comprehensive Cancer Center, Department of Hematology, Helsinki, Finland

Background: The treatment results in Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ ALL) have improved significantly in the era of tyrosine kinase inhibitors (TKIs). However, many patients relapse despite having received intense treatments with initially favorable responses. TKI therapy is known to modulate the immune system, and it may play a critical role in keeping the leukemia under control. However, little is known about the status of the immune system in patients with Ph+ ALL. Especially with the emerging immunotherapies in sight, it is vital to chart the immunological landmarks that could help us direct the treatment towards a more personalized course.
Aims: To characterize the immunological microenvironment in Ph+ ALL bone marrow (BM) by multiplex immunohistochemistry (IHC).
Methods: Ph+ ALL BM biopsies from the diagnosis stage were collected from Helsinki University Hospital and Tampere University Hospital (N=31). BM biopsies from non-leukemic (NL) controls (N=14) were used as a reference. Samples were hematopathologically evaluated and a tissue microarray (TMA) was constructed by selecting two BM cores with high leukemic cell infiltration per patient. The TMA sections were stained with both fluorescent and chromogenic dyes for six markers and nuclei simultaneously enabling cytometric analysis at cell-level resolution. Marker panels included T and B lymphoid cells, NK and dendritic cells, macrophages as well as myeloid derived suppressor cells. Furthermore, we analyzed immune checkpoint molecules (PD1, LAG3, OX40, TIM3, CTLA4) and their ligands (PD-L1, PD-L2, HLA-G, HLA-ABC) alongside with various activation markers (granzyme B, CD45RO, CD25, CD57, CD27). After the staining, the cells were segmented and quantified with the image analysis software CellProfiler and the cell analysis software FlowJo.
Results: The CD4+/CD8+ ratio was lower in Ph+ ALL BM *versus* NL BM (1.3 [Interquartile range (IQR) 1.0-1.9] *vs* 2.0 [IQR 1.7-2.4], p=0.0134) indicating that there are relatively more CD8+ T cells in the leukemic than in the non-leukemic marrow. The ratio of memory CD4+CD45RO+ T cells in Ph+ ALL BM *versus* NL BM was elevated (21.0% [IQR 16.7-28.5] *vs* 13.0% [IQR 8.7-15.9] of CD4+ T cells, p=0.0044). The difference in memory CD8+CD45RO+ T cells was not significant (p=0.36). Further analysis of the T cell phenotype showed increased proportion of both PD1-positive helper T cells and PD1-positive CD8+ T cells in Ph+ ALL BM *vs* NL BM (29.7% [IQR 17.5-50.1] *vs* 6.9% [IQR 5.7-8.9], of CD4+ cells, p<0.0001 and 28.8% [IQR 13.2-38.0] *vs* 14.9% [IQR 9.6-18.7], of CD8+ cells, p=0.0107). The ratio of OX40-positive helper T cells was also higher in Ph+ ALL BM (27.1% [IQR 21.6-33.25] *vs* 18.5% [IQR 14.8-21.9], of CD4+ cells, P=0.0001), but no difference was observed in the proportion of OX40-positive CD8+ T cells (P=0.49).
Summary/Conclusions: Multiplex IHC enables ample cytometric evaluation of different immune cell subtypes in their original microenvironmental context of the bone marrow. The TMA format not only allows analysis of tens of BM samples in parallel but also serves as a retrospective, easy-access archive for any follow-up studies. Ph+ ALL BM is characterized by a decrease in the CD4+/CD8+ ratio and an increase in the proportion of CD4+CD45RO+ T cells in comparison with the non-leukemic controls. The proportion of PD1-expressing T cells is also elevated. However, the heterogeneity between patients is marked. The analysis of other marker panels is presently ongoing, as well as correlation to clinical and treatment outcome parameters.

PB1615

CDKN2A/P16INK4A DELETION IS NOT A POOR PROGNOSIS PREDICTOR IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED ACCORDING TO PROTOCOL RALL-2009

P. Inga[1,*], O. Tatiana[1], P. Elena[1], T. Vera[1], G. Olga[1], R. Michail[1], K. Sergey[1], A. Zalina[1], S. Valery[1]
[1]National Research Center for Hematology, Moscow, Russian Federation

Background: CDKN2A/p16^{INK4a} deletion is a frequent cytogenetic abnormality in acute lymphoblastic leukemia (ALL), ranging from 18% to 45%. In pediatric group of patient's p16^{INK4a} deletion was associated with T-cell ALL phenotype and poor event-free survival. The prognostic impact of CDKN2A/p16^{INK4a} deletion in adult ALL patients appear controversial.
Aims: To evaluate the prognostic impact of the CDKN2A/p16^{INK4a} deletion in adult patients with acute lymphoblastic leukemia.
Methods: We present the results of the CDKN2A/p16^{INK4a} deletion in 110 adult patients with newly diagnosed Philadelphia –negative ALL, which were treated by RALL-2009 (NCT01193933) in our center since June 2009 till September 2016. Patients characteristics: the median of age was 26 years old (range 15 -54), the median white blood cell (WBC) count was 16.9×10^9 /L (range: 0.4-785×10^9 /L), the median blasts cells count in the bone marrow (BM) was 84.4% (range: 0-98). Sixty-five (59%) of the 110 patients had a B-cell phenotype, 42 (38%) had a T-cell phenotype, 3 (2.7%) patients - biphenotypical ALL. Interphase fluorescence *in situ* hybridization (FISH) was performed for detection CDKN2A deletion, TEL/AML1, MLL rearrangement, MYC (8q24.21) translocation, TP53 deletion, iAMP21.

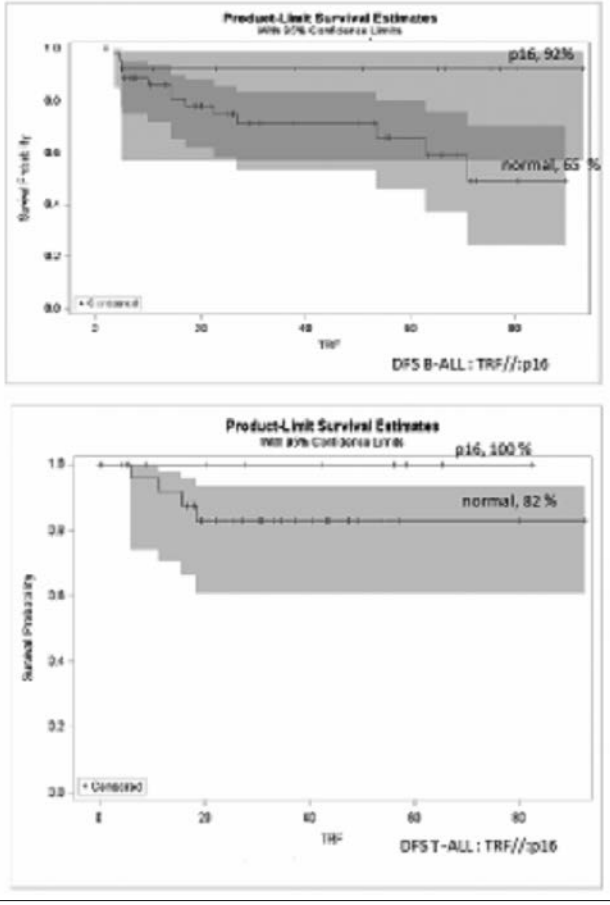

Figure 1.

Results: The prevalence of the CDKN2A deletion in all studied population was 24,5% (27 cases). The frequency of homozygous deletions was 70% (in 19 cases), heterozygous deletion was 30% (in 8 cases). CDKN2A deletion was detected in 14 (52%) patients with precursor-B phenotype, in 11 cases (41%) with T-ALL and in 2 (7%) cases with biphenotypical ALL. Our study demonstrated that CDKN2A deletion had no significant association with age, sex, WBC counts, BM blasts, risk stratification groups, complete remission (CR) and relapse rate in B-cell ALL. We didn't reveal any significant differences in OS, clinical and laboratory dates between groups of patients with homozygous and heterozygous deletion of the CDKN2A deletion. The analysis for T-ALL has detected that CDKN2A deletion was strongly associated with high WBC count (the median is 86×10 /L, p=0.006), with high lactate dehydrogenase (LDH) level (the median is 3062 E/L, p=0.0004) and no assonating with CR and replace incidence was found. We didn't revealed relationship between CDKN2A deletion and MLL, TEL/AML1 rearrangement, MYC translocation, TP53 mutation and iAMP21. CDKN2A deletion didn't have statistically significant impact on outcome of patients. The five-year overall survival (OS) for patients with and without deletion was 84% and 77% (p=0, 40); free survival (DFS) was 91% и 71% (p=0, 09), respectively. OS for patients with B-cell ALL with and without deletion was 85% and 76% (p=0, 35); DFS was 92% and 65% (p=0, 07), respectively. OS for T-cell ALL patients with and without deletion was 90% and 80% (p=0, 63); DFS was 100% and 82% (p=0, 24), respectively. (Figure 1).
Summary/Conclusions: We were unable to demonstrate prognostic value of the CDKN2A deletion in adult ALL patients and did not find significant association between deletion of the CDKN2A gene and with known cytogenetic prognostic factors. However patients with T-cell ALL and CDKN2A deletion had a more aggressive initial clinical features (high level WBC and LDH), but it didn't associate with poor outcomes including overall survival.
Deletion of CDKN2A is not adverse prognostic factor in adult ALL treated according to protocol RALL-2009.

PB1616

FREQUENCY AND CLINICAL IMPACT OF CDKN2A/B GENE LOCUS IN AN ADULT T-ALL COHORT OF PATIENTS ENROLLED IN THE SPANISH PETHEMA GROUP PROTOCOLS

Background: Recurrent 9p21 deletions involving *CDKN2A/CDKN2B* locus are frequent in ALL. The very few data regarding their prognostic significance in adult T-ALL have shown that homozygous deletions of the *CDKN2A/CDKN2B* locus are associated with improved overall survival (OS).
Aims: We precisely characterized the copy number status (CNA) of *CDKN2A/CDKN2B* locus by discriminating deletions in A or B gene in order to elucidate its clinical impact separately.
Methods: Samples from 30 adult T-ALL cases included in high-risk protocols from the PETHEMA group were analyzed by CytoScan array (Affymetrix). Additionally, we set up a genomic qPCR to screen for *CDKN2A* and *CDKN2B* deletions in samples with few or not enough quality DNA (n=53). We corrected our CNA values for the normal cells (2N) contaminant present in the diagnosis samples. In addition, the results obtained by the array and/or qPCR were checked by FISH, when samples were available. Cumulative incidence of relapse (CIR) and OS were analyzed after censoring the patients at the time of allogeneic hematopoietic stem cell transplantation.
Results: qPCR results showed that most of the 9p21 losses corresponded to homozygous deletions in both genes (36%, 19/53), while heterozygosis deletions corresponded to 5.7% (3/53) and different CNA status between *CDKN2A* and *B* to 28% (15/53) of the samples. Globally alterations in *CDKN2A/B* locus were observed in 70% (37/53) of patients. Results obtained by the array corroborate the findings obtained by qPCR. The resolution of the array allowed us to distinguish between homozygosis in *CDKN2A* and heterozygosis on *CDKN2B*. The FISH analysis corroborated the homozygous deletion in the CDKN2A/B locus in all the cases analyzed. With that, we ask for clinical implications of CDKN2A/B CNA status in 49 cases with adequate follow-up. Median age (range) was 34 (16-68) years, 76% males, median WBC count 34 (0.6-431.0) x10^9/L. Immunophenotype: pro-T+pre-T (n=21), cortical T (n=21), mature T (n=7). CR was achieved in 92% (45/49) and MRD levels <0.1% at the end of induction were attained in 81% of patients. A trend for better OS was observed for patients with heterozygous or homozygous deletion of *CDKN2B* (61% [40%>82%]) *vs* non deleted patients (25% [0%>54%],(p=0.084), whereas no clinical impact was observed for the CNA status in the *CDKN2A* gene. No influence of *CDKN2A* or *CDKN2B* CNA status on CIR was observed. By multivariate analysis only the MRD level at the end of induction influenced on OS (p=0.028, HR=5.58 [1.21 ; 25.79]) and on CIR (p=0.07, HR= 3.67 [0.90-15.63]).
Summary/Conclusions: *CDKN2A/B* locus abnormalities, mainly homozygous deletions, were found in 70% of adult T-ALL patients. Different CNA status was found for *CDKN2A* and *CDKN2B*. Although homozygous deletion in *CDKN2B* was associated with a trend for better OS, the level of MRD was the only prognostic factor for OS in these patients.
Supported by 2014 SGR225 (GRE) from CERCA Programme/Generalitat de Catalunya, and by funds from Josep Carreras International Foundation, "la Caixa" Foundation and Celgene Spain.

PB1617

BUTEIN KILLS ACUTE LYMPHOBLASTIC LEUKEMIC CELLS *IN VITRO* AND *IN VIVO* THROUGH FOXO3A AND CASPASE-DEPENDENT APOPTOTIC PATHWAYS

Y.-L. Tang[1,*], L.-B. Huang[1]
[1]Department of Pediatrics, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Acute lymphoblastic leukemia (ALL) is a common hematological malignancy in children. Discovering and developing effective chemotherapeutic drugs are needed for ALL.
Aims: In this study, the anti-leukemic effect and the potential molecular mechanisms of butein on ALL were investigated.
Methods: We examined the rate of apoptosis of CEM-C7 (T-ALL), CEM-C1 (T-ALL), MOLT-4 (T-ALL), RS4-11 (B-ALL) cell lines and primary ALL blasts exposed to various concentrations of butein for 24 h using the flow cytometry. We tested the expression of the caspase-9, poly ADP-ribose polymerase (PARP), nuclear Forkhead Class box O3a (FOXO3a) and BCL-2 interacting mediator of cell death (BIM) using western blot assay. We established the xenograft mouse model to examine the anti-leukemic effect of butein *in vivo*.
Results: Butein was found to significantly induce the cellular apoptosis of ALL cell lines and primary ALL blasts in a dose-dependent manner. It also activated the cleavage of caspase-9 and PARP. We also found that butein promoted FOXO3a localization, enhanced the binding of FOXO3a on the BIM gene promoter and then increased the expression of BIM. Moreover, we showed that FOXO3a knockdown significantly decreased the apoptosis by butein, whereas overexpression of FOXO3a enhanced the butein-induced apoptosis. However, overexpression of FOXO3a mutation (C-terminally truncated FOXO3a DNA-binding domain) decreased the apoptosis by butein through decreasing the expression of BIM. Furthermore, treatment with butein was highly efficacious *in vivo*, with enhanced reduction of tumor burden in a xenograft model of ALL.
Summary/Conclusions: Our results therefore demonstrate the therapeutic potential of butein for ALL via FOXO3a and caspase-dependent apoptotic pathways.

Background: Childhood acute lymphoblastic leukemia (ALL) is the most common of pediatric malignancies, but intensive chemotherapy now allows to obtain complete remission in over 90% of the cases. Nevertheless, 1 out of 5 children will relapse.
Aims: In order to identify new markers prognostic of relapse, we analyzed SNP arrays of paired diagnosis and relapse samples from 8 B-ALL children.
Methods: The cohort included 3 males and 5 females, aged between 6 months and 21 years old (median age 4 years old). Bone marrow samples were analyzed by multiparameter flow cytometry, standard karyotype and FISH. SNP array (Affymetrix®) performed on cryopreserved cells at diagnosis and relapse investigated copy number alterations (CNA) and loss of heterozygosity (LOH). *TP53* mutation was studied on paired samples by Sanger sequencing.
Results: No modification was observed in the EGIL classification between diagnosis and relapse. Diagnostic cytogenetics prognosis was good for 3 children, poor for 3 (iAmpAML1, *KNMT2A* and complexe caryotype) intermediate for 2 (normal karyotype). Three patients showed additional karyotypic anomalies at relapse. SNP array showed a mean of 10 CNA and 3 LOH at diagnosis with 4 CNA and 0,6 LOH modulations at relapse. Seven of the 8 patients presented modulation in CNA and LOH during evolution with a median of 4. Some anomalies observed by cytogenetics were refined by SNP analysis, notably all chromosomal gains and losses were recovered and precisely located. More-

over, a t(4;8) translocation was found to be more complex with 7 and 8 CNA on chromosomes 4 and 8. Patients with the most CNA and LOH also had a complex karyotype. Anomalies were observed in hot spot regions in 9p (encompassing *CDKN2A/2B*, *PAX5* and *JAK2*) for 5 patients and 12p (including *ETV6*) for 3. Stable CNA were observed in the *JAK/STAT* pathway in 2 patients *(JAK2)* and LOH in the *RAS/MAPk* pathway *(NRAS)* in 1. Using the genetic classification of Moorman *et al* based on SNP array for 8 genes at diagnosis (*IKZF1, CDKN2A/2B, PAR 1, BTG1, EBF1, PAX5, ETV6* and *RB1*), SNP reclassified our patients in 3 of good prognosis and 5 of poor prognosis, with a median of 2 CNA for the 8 genes of interest. The 2 patients with cytogenetic intermediate prognosis would thus probably have been considered for a more intense therapeutic regimen, *i.e.* allogeneic stem-cell transplantation. Moreover, SNP showed that 2 patients acquired an *IKZF1* deletion, also of poor prognosis, while none of the children had *TP53* mutation at diagnosis nor relapse.
Summary/Conclusions: SNP array allowed to identify additional anomalies (compared to karyotype) in all children tested and changed the prognostic value of diagnostic anomalies. Moreover, the identification of anomalies in the *JAK/STAT* pathway could indicate a treatment by tyrosine kinase inhibitors, which would possibly have positively modified outcome. Taken together, this new technology combined with classical analyses at diagnosis might modify therapeutic options in childhood ALL, especially in the subgroup with a normal karyotype.

PB1619

SCREENING OF NUDT15 GENE VARIANTS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

D. Aslar Oner[1,*], D.F. Akin[1], K. Sipahi[1], M. Mumcuoglu[1], N. Oner Battaloglu[1], S. Tasdelen[1], U. Ezer[1], S. Emir[1], E. Kürekci[1]
[1]Lösante Hospital, ANKARA, Turkey

Background: In cells, while DNA bases can be protected by double helix formation and nucleosome packaging, deoxyribonucleotide triphosphates are unprotected, thus, are vulnarable to damage. One of the enzymes which are responsible for removing damaged nucleotides is Nudix hydrolase15 (NUDT15). NUDT15 works as a negative regulator in thiopurine metabolism. Thioguanines are active metabolites of thiopurines. Mechanisms of action of thioguanines are disruption of DNA synthesis and induction of apoptosis. NUDT15 inhibits incorrect base pairing and apoptosis through catalysis of thioguanine hydrolysis. Tanaka *et al.* claimed that, besides *TPMT* variants in Japanese patients, there might be possible additional factors that may influence thiopurine toxicity. They reported that *NUDT15* variants are more specific to Asian population when compared to European people. As far as we know, this is the first study on screening of possible variants in the first exon of *NUDT15* in Turkish children with precursor B-cell acute lymphoblastic leukemia (Pre-B ALL).
Aims: In this study, our aim was screening of gene variants in first exon of NUDT15 in pediatric group of patients diagnosed with Pre-B ALL.
Methods: Our study group was composed of 83 patients aged between 1-15 diagnosed with Pre B-ALL at Lösante Hospital. DNA samples were isolated by using MagNa Pure isolation system. First exon of *NUDT15* was amplified by PCR reaction. After PCR purification, sequencing was performed.
Results: After screening of first exon of *NUDT15*, we detected two variations. First variation was intronic insertion which was defined as rs3831098 (c.158+52_158+53insGGGGCGTGCGCAGAGGGACGATCTC). The other intronic variation was defined as rs79687000 (c.158+117C>T). rs3831098 was determined in one of the 83 patients and rs79687000 was found in three out of the 83 patients (Tbale 1).

Table 1.

NUDT15 Variants in Children with Leukemia

Our study (n:83)	rs3831098	c.158+52_158+53insGGGGCGTGCGCAGAGGGACGATCTC	-	Intron 1	1/83 (1.2)
	rs79687000	c.158+117C>T	-	Intron 1	3/83 (3.6)

Summary/Conclusions: The changes in *NUDT15* that we found have not been previously reported in pediatric ALL patients. We do not know if these changes have an effect on pre-mRNA or "splice" regions and ALL. This issue needs further investigations in a large number of children with leukemia. We are planning the screening of other exons of *NUDT15* in order to evaluate for possible applications to clinical practice (*e.g.* cytopenia).

COMPREHENSIVE MOLECULAR CYTOGENETIC ANALYSES OF BONE MARROW CELLS IN 64 CHILDREN WITH T-ALL REVEALED PROGNOSTICALLY RELEVANT RECURRENT FINDINGS

L. Lizcova[1,*], Z. Zemanova[1], E. Prihodova[1], L. Pavlistova[1], K. Svobodova[1], E. Mejstrikova[2], O. Hrusak[2], P. Luknarova[2], I. Janotova[3], L. Sramkova[3], J. Stary[3], K. Michalova[1]
[1]Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General University Hospital and 1st Faculty of Medicine, Charles University in Prague, [2]CLIP - Childhood Leukaemia Investigation Prague, Department of Paediatric Haematology and Oncology, [3]Department of Paediatric Haematology and Oncology, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital , Prague, Czech Republic

Background: T-ALL represents 15% of newly diagnosed children with ALL and it is a clinically and genetically heterogeneous disease. Despite the use of intensive chemotherapy, relapse occurs in almost 25% of patients whose outcome remains dismal. Visible chromosomal aberrations are seen in approximately half of the cases, while cytogenetically cryptic aberrations are observed in almost all cases of T-ALL. However, prognostic implication of majority of them still remains unclear.
Aims: The aim of this study was to retrospectively and prospectively analyze bone marrow cells of children with T-ALL, to determine a frequency of recurrent cryptic chromosomal aberrations and to assess their impact on event free (EFS) and overall survival (OS).
Methods: Bone marrow cells of all patients were analyzed at the time of diagnosis by combination of conventional and molecular cytogenetic methods. For detection of the most frequent known chromosomal changes, *i.e.* rearrangements of *TCR* loci (*TRA*-14q11, *TRB*-7q34, *TRG*-7p14) and *TLX3* gene (5q35), deletion of *CDKN2A* (9p21) and amplification of *ABL1* (9q34), interphase FISH with locus-specific probes (Dako, Abbott Molecular) was used. Complex chromosomal rearrangements were proved by multicolor FISH and multicolor banding (24*X*Cyte/*X*Cyte Probe Kit; MetaSystems) or CGH-SNP array (SurePrint G3 Cancer CGH+SNP 4x180K, Agilent). For OS and EFS Kaplan-Maier analysis with Mantel Cox test was done.
Results: During the years 1996-2016 we examined archived material of 64 children with T-ALL (19 girls and 45 boys, median age 8.25 years). In total, chromosomal aberrations were detected in 86% of patients. The most frequent aberration was deletion of *CDKN2A* gene, which was found in 35/64 patients (19x homozygous, 16x heterozygous). Rearrangements of *TCR* loci were detected in 17/64 children (11x *TRA,* 6x *TRB)*. *TLX3* gene rearrangement was established in 15/64 patients. No aberration of *TRG* gene and amplification of *ABL1* were found. Complex chromosomal aberrations were proved in 12/64 children. In two cases, isochromosome of the long arm of chromosome 9 was found. 48 patients are living in the first/second complete remission. Relapse of the disease occurred in 17 patients, 16 children died. Best outcome (EFS and OS) was associated with *TRA* translocations ($p<0.05$). Patients with *TLX3* rearrangement had significantly shorter OS and EFS ($p<0.05$).
Summary/Conclusions: Using molecular cytogenetic methods cryptic recurrent aberrations were proved in vast majority of patients. Rearrangement of *TLX3* gene was related to poor outcome in contrast to *TRA* translocations associated with more favorable course of the disease. Our work attempts to clear up the significance of chromosomal aberrations related to childhood T-ALL in order to facilitate the patients´ stratification into cytogenetic prognostic groups and to identify patients at an increased risk of relapse similarly like it has been adopted in pB-ALL.

ADULT PRIMARY ACUTE LEUKEMIA SAMPLES WITH CHROMOSOMAL TRANSLOCATIONS GROW WELL IN IMMUNODEFICIENT MICE, BUT ARE DIFFICULT TO TRANSDUCE WITH LENTIVIRUSES

B.C. Heckl[1,*], M. Carlet[1], M. Grunert[1], B. Vick[12], C. Roolf[3], C. Junghanß[3], K. Spiekermann[2,4], W. Hiddemann[2,4], I. Jeremias[1,2,5]
[1]AGV, Helmholtz Zentrum Muenchen, [2]German Cancer Consortium , Muenchen, [3]Department of Internal Medicine III, University, Rostock, [4]Internal Medicine III, [5]Dr. von Haunersches Kinderspital, Ludwig Maximilian University, Muenchen, Germany

Background: Acute leukemia (AL) is a severe disease of the hematopoietic system and associated with a poor outcome for patients. Patient derived xenograft (PDX) mouse models provide an attractive tool to engraft and grow primary tumor cells. In contrast to culture growth, samples can be monitored in a consisting

microenvironment. This powerful tool provides the baseline for further experiments like preclinical treatment trials or biology studies. While good engraftment rates were published for primary pediatric ALL samples, engraftment rates of adult ALL samples might be inferior, but remain largely elusive.
Aims: This study aimed to determine engraftment and growing ability of primary adult AL samples in immunodeficient mice. Genetic engineering was performed to evaluate transduction efficiencies by lentiviruses in PDX AL cells.
Methods: Primary adult ALL and AML samples were transplanted into NSG mice in the absence of total body irradiation. Both frozen as well as fresh patient material was used. Human CD45 and human CD38 were stained in blood to monitor successful engraftment. Mice were sacrificed before coming down with leukemia. Isolated cells from bone marrow and spleen were analyzed by flow cytometry. Genetic engineering was performed using lentiviral vector systems and monitored by expression of fluorochrome markers and flow cytometry.
Results: Engraftment and growth was successful in NSG mice in 12 out of 15 primary adult ALL samples. Frozen samples showed a longer median engraftment time with 114.4 days, whereas fresh samples could already be isolated with an average time of 75.29 days. Generally, the engraftment time varied form 47 days up to 166 days and was shortened for slow samples over several passages. Genetic engineering was successfully performed using lentiviral transduction to introduce expression of fluorescent colours for cell marking and monitoring in further experiments. Lentiviral transduction was performed in 8 ALL samples with BCR-ABL rearrangement and 2 MLL-AF4 ALL samples. Adult ALL PDX samples with chromosomal translocations showed very low transduction rates around 1%. Three AML samples with MLL-AF6, MLL-AF9 and MLL-AF10 translocation were analysed for this study. Interestingly and in contrast to ALL, transduction efficiency for AML rearranged samples was high with up to 60%. These values are similar to non-rearranged ALL samples having transduction rates between 30% up to 80%.
Summary/Conclusions: In summary, we observed a high engraftment rate of primary adult ALL samples in immunodeficient mice which was above what we anticipated from the literature. Adult PDX ALL samples can be transduced with lentiviruses with identical high transduction efficiency as pediatric samples, with an age independent exception of AL PDX cells with BCR-ABL or MLL translocations.

SYNERGIC CHEMOTHERAPEUTIC EFFECT OF MENADIONE COMBINED WITH EPIGALLOCATECHINE-3-GALLATE OR DOXORUBICIN IN A HUMAN CELLULAR MODEL FOR ACUTE LYMPHOBLASTIC LEUKEMIA
A. Garaiman[1,2,*], I. T. Tofolean[1], R. M. Babes[1], C. Ganea[1], I. Baran[1]
[1]Department of Biophysics, "Carol Davila" University of Medicine and Pharmacy- Bucharest, [2]Department of Hematology, Coltea Clinical Hospital, Bucharest, Romania

Background: Epigallocatechine-3-gallate (EGCG) and menadione (vitamin K3; MD) are known as potent apoptogens in cellular models for acute lymphoblastic leukemia (ALL) –Jurkat T cells.
Aims: The goal of this study was to explore the chemotherapeutic potential of MD combined with EGCG or DOX, and to determine whether there is a synergic interaction between these agents that could significantly enhance their antitumoral effect in a cellular model of ALL. We investigated the antiproliferative effect of EGCG and MD, applied alone or in combination EGCG:MD and MD:DOX respectively on human leukemia Jurkat lymphoblasts. Some underlying cellular mechanisms were also scrutinized.
Methods: Cell suspensions of Jurkat lymphoblasts were treated at various concentrations of EGCG, MD and DOX. Clonogenic survival was evaluated as the colony forming capacity in 96-well plates. Cell cycle and apoptosis/necrosis were determined by flow cytometry using the fluorescent indicators propidium iodide and Annexin V-FITC/7-AAD, respectively. Determination of oxidative stress and mitochondrial polarization was performed by spectrofluorimetry, using the fluorescent probes CM-H_2DCFDA and JC-1, respectively.
Results: EGCG decreased clonogenic survival (IC_{50}=117 μM and Hill coefficient *h*=3.17) and mitochondrial calcium in a dose-dependent manner (IC_{50} =97 μM, *h*=2.53). Furthermore, data show that there is no correlation between the level of mitochondrial calcium ($[Ca^{2+}]_m$) and mitochondrial membrane potential ($\Delta\psi_m$) (Pearson correlation coefficient r= −0.100) or between $[Ca2+]_m$ and reactive oxygen speacies (r=−0.437) production, thus EGCG exerted a depolarizing effect at the mitochondrial level, most likely via interference with the opening of the mitochondrial permeability transition pore. The combination EGCG:MD induced cell cycle arrest in G_2/M and S phases in a synergic manner (the measured viability was: ~91% for EGCG 50 μM, ~72%MD 25 μM, ~20% for their combination). The existence of two binding sites for EGCG is suggested, both modulated by MD, implying that MD is an allosteric modulator of the EGCG-induced depolarization. Fluorescence induced by treatment with EGCG alone, MD alone and EGCG:MD in combination was 172%, 101% and 387%, respectively, suggesting that EGCG and MD interact with the second specific target in a synergic manner. DOX induced cell cycle arrest, and clinical doses of DOX generated oxidative stress. MD augmented this effect, enhancing the antiproliferative effect of DOX most likely by increasing the affinity of DOX for nuclear DNA.
Summary/Conclusions: Our results support the notion that the combinations EGCG:MD and MD:DOX exert a strong synergic antiproliferative effect in human leukemia Jurkat cells and encourage further studies to test the clinical utility of this association in ALL therapy.

FOCAL ERG DELETIONS AND DUX4 FUSIONS IN CELL LINES DERIVED FROM B CELL ACUTE LYMPHOBLASTIC LEUKEMIA
H. Quentmeier[1,*], R.A. MacLeod[1], C. Pommerenke[1], H.G. Drexler[1]
[1]DSMZ, Braunschweig, Germany

Background: *DUX4* has recently been presented as new oncogenic driver in B cell acute lymphoblastic leukemia (pre B-ALL) of adolescents and young adults [1]. Translocations of *DUX4*, especially those with the *IGH* locus led to high expression of the corresponding fusion gene. *DUX4* then triggered the expression or a novel isoform of the *ETS* transcription factor *ERG* in pre B-ALL [2]. Focal deletions of exons 3-9 were a second cause for short *ERG* variants. Up to 7% of pre B-ALL showed deregulated expression of both genes, *DUX4* and *ERG* [2].
Aims: We set out to find pre B-ALL cell lines with *DUX4* translocation and *ERG* deletion as potential model systems for this novel subtype of pre B-ALL.
Methods: We screened a panel of ALL cell lines for aberrant expression of *DUX4* mRNA as potential indicator for *DUX4* translocations. Genomic PCR was performed to detect focal *ERG* deletions, qRT-PCR showed expression of alternative *ERG* exon 6, transcriptional target of *DUX4*.
Results: Genomic PCR showed that 2/66 pre B-ALL cell lines (NALM-6, SUP-B15) tested carried deletions targeting *ERG* exon 5. Results of *DUX4* qRT-PCR (Taqman probe Hs03037979_g1) were surprisingly inconsistent with Western blot analysis - which could only in part be explained by *DUX4* being a one-exon gene. NALM-6 was the only cell line expressing the DUX4 protein. Likewise, the alternative *ERG* transcript with alternative exon 6 was observed in NALM-6 only.
Summary/Conclusions: In conclusion, focal *ERG* deletions in pre B-ALL cell lines (2/66) occur at similar frequencies as in the primary tumor. Cell line NALM-6 carries the *DUX4-IHG* translocation, expresses the DUX4 protein and an *ERG* mRNA variant including the alternative exon 6. *ERG* deletions were present in cell lines NALM-6 and SUP-B15. However, cell line SUP-B15 did not express DUX4 protein and consequently also not alternative *ERG* exon 6 transcript. These results indicate that focal *ERG* deletions are not a safe indicator for aberrant expression of *DUX4*. Cell line NALM-6 is presented as model system for *DUX4/ERG* pre B-ALL.

Background: Approximately 90% of children with acute lymphoblastic leukemia (ALL) are cured with current treatment protocols. However, 15-20% of the patients still experience disease relapse. Moreover, a small subset of patients develop secondary therapy-related leukemia or myelodysplasia.
Aims: We present a case of a 11-year-old boy with the history of relapsed ALL followed by aberrant proliferation of several different subsets of precursor cells in bone marrow (BM), which was associated with progressive ineffective hematopoiesis.
Methods: A boy diagnosed with standard risk B-cell Precursor (BCP) ALL in 10-2009 was treated until 12-2011 with frontline chemotherapy according to ALL-IC BFM 2002 protocol. In 12-2012, one year after treatment completion he developed late combined ALL relapse (BM and testis). Unilateral orchidectomy was performed, while the biopsy of the second testis showed no leukemic infiltration. He received 2nd line chemotherapy according to IntReALL 2010 and local radiotherapy for the testicular area. Despite the borderline minimal residual

disease (MRD) at the end of induction treatment, the SCT procedure wasn't executed due to the lack of suitable matched donor. In June 2014, during maintenance treatment, the patient showed persistent pancytopenia.
Results: BM aspirate morphology showed 5% of blasts. However, detailed 8-color flow cytometry according to the EuroFlow protocols revealed no cells with BCP-ALL-specific immunophenotype, but several subsets of BCP with abnormal maturation (total 3.5%) and plasmacytoid dendritic cell precursors (2.1%). After cessation of maintenance therapy in 02-2016, continuous progression of infiltration was observed. Subsequent BM aspirates revealed increasing proliferation of five different cell populations which show rare, aberrant immunophenotypes. Three of them represented immature BCP: B1 (CD34+/CD19-/CD10+dim/CD20-/nTDT+dim/CD22+dim/CD38++/CD117+/CD123/HLA-DR+/++/SSCintermediate), B2 (CD34+/CD19+/CD10+heterogeneous/CD20-/nTDT+/++/ CD22+/CD38++/CD117-/CD123-/HLA-DR+/++/SSClow), and B3 (CD34-/CD19dim/CD10dim/CD20-). The fourth population corresponded to non-lymphoid/non-dendritic cell precursors (CD34+/CD19-/CD10-/CD20-/nTDT-/CD22-/CD38++/CD117-/CD123-/HLA-DR++/SSChigh) and the fifth population showed the features of plasmacytoid dendritic cell precursors with aberrant CD10 expression (CD34+dim/CD19-/CD10+/CD20-/nTDT-/CD22+/CD38+dim/CD117-/CD123++/HLA-DR+/SSC intermediate). Analysis of clonality via PCR assessment of *IGH* gene rearrangements revealed polyclonal pattern in all BCP subsets. Cytogenetic analysis showed an altered 45,XY,del(4)(q31?),-7,der(9) [20] karyotype, while interphase FISH showed monosomy 7 in >80% of all BM cells. Retrospective FISH analysis at 1st relapse showed normal chromosome 7 in all cells. CytoScan® 750K array (Affymetrix®) analysis in 10 sorted cell populations showed a complex karyotype highlighting monosomy of chromosome 7 and loss of chromosome 4q (del4q21.1-q25; 40Mb) associated with gain of chromosome 14 (14q32.33; 200Kb). In addition, several gains of minor chromosomal regions were detected in CD34+/CD19-/CD10- and CD34+/CD10+/CD19- cells. Due to progressive increase of all subsets of abnormal precursor cells (27,5% in total) and hepatosplenomegaly, further treatment direction was set at haploidentical stem cell transplantation.
Summary/Conclusions: We present an abnormal secondary proliferation, with increased numbers of aberrant BCP, myeloid and plasmacytoid dendritic cell precursors resulting from stem cell defect hallmarked by monosomy 7.

PB1625

IDENTIFICATION OF KEY GENES AND CONSTRUCTION OF MICRORNA–MRNA REGULATORY NETWORKS IN MULTIPLE MYELOMA BY INTEGRATED MULTIPLE GEO DATASETS USING BIOINFORMATICS ANALYSIS

Z. Chi[1,*], Z. Gong[2,3], W. Yang[2]
[1]Pediatric Hematology, [2]Hematology, Shengjing Hospital of China Medical University, Shenyang, China, [3]Hematopathology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: T cell acute lymphoblastic leukemia (T-ALL) is a hematopoietic clonal malignancy caused by the malignant transformation of T lymphocyte driven by gene mutation. The prognosis of T-ALL is poor and early relapse is common.
Aims: We aimed at looking for specific and effective therapeutic target for T-ALL and eventually cure this form of leukemia by targeted therapy.
Methods: Bone marrow mononuclear cells (BMMC) are collected from bone marrow samples of T-ALL patients, including at initial presentation (n=46), during first CR (n=23) and at relapse (n=6). The expression level of mRNA encoding L-cellular Fas-associated death domain-like interleukin-1β converting enzyme inhibitory protein (c-FLIP) was assessed by realt time PCR. Changes in the expression level of HDAC before and after chidamide treatment were also assessed by western blot. Necroptosis and apoptosis after chidamide treatment were assessed by flow cytometry. Changes in expression level of c-$FLIP_L$ protein before and after treatment were assessed by western blot. Expression level of early apoptotic protein, key proteins of necroptosis were assessed by western blot.The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis were assessed by western blot. The regulating effect of chidamide on downstream genes of NF-κB pathway including cyclinD1, TNFα, IL-2, IL-8 were assessed by real- time PCR.
Results: The expression level of c-$FLIP_L$ mRNA is significantly higher in patients at initial presentation and relapse, compared to those at complete remission and healthy control. The expression level of c-$FLIP_L$ mRNA is associated with patient risk stratification, white blood cell count at initial presentation, serum level of lactate dehydrogenase (LDH), serum level of hydroxybutyrate dehydrogenase (HBDH), CD45, HLA-DR, SIL-TAL1 fusion gene and complex karyotype, and is not associated with age, sex, plasma fibrinogen level, and the chromosomal aberration 6q-. Patients who did not achieve CR during first chemotherapy had a higher c-$FLIP_L$ mRNA level than those who did ($p<0.05$).The expression level of histone deacetylase is higher in bone marrow mononuclear cells of T-ALL patients, Jurkat and HUT-78 cell lines. After treatment with chidamide, the expression level of histone deacetylase was significantly decreased in both cell lines.Chidamide induced necroptosis and apoptosis in Jurkat and HUT-78 cell lines. After apoptosis inhibitor was applied, chidamide mainly exert its effect of inducing cell death by inducing necroptosis. Chidamide inhibits the transduction and translation to c-$FLIP_L$ gene. When apoptosis is inhibited, chidamide upregulates the expression level of receptor-interacting protein 3 (RIP3) and the phosphorylation level of mixed lineage kinase domain-like (MLKL). After treatment with chidamide, the phosphorylation level of I-κB and p65 protein were both significantly decreased.
Summary/Conclusions: c-$FLIP_L$ mRNA expression level is abnormally high in T-ALL patients both at initial presentation and at relapse. The expression level of c-$FLIP_L$ is associated with risk stratification, white blood cell count, serum LDH level, serum HBDH level, CD45, SIL-TAL1 fusion gene, complex karyotype and disease outcome. c-$FLIP_L$ could be used as a prognostic marker in T-ALL.Chidamide suppresses histone deacetylation in Jurkat and HUT-78 cell lines.Chidamide induces necroptosis in Jurkat and HUT-78 cell lines by down regulating the transcription and translation of c-$FLIP_L$ gene.Chidamide induces necroptosis in Jurkat and HUT-78 cell lines via the classical NF-κB signaling pathway.

CYP1A1 AND CXCL12 GENE POLYMORPHISMS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

E. Kampouraki[1], M. Lourou[1], E.-D. Ampazoglou [1], M. Karachaliou[1], E. Stiakaki[1,*]
[1]Pediatric Hematology - Oncology, University Hospital of Heraklion, University of Crete, Heraklion, Greece

Background: Acute lymphoblastic leukemia (ALL) is the most common type of childhood leukemia and represents one third of all pediatric malignancies. Despite the high survival rates (more than 80%), a noteworthy number of children relapse and for them the outcome remains poor. Epidemiological studies that examined possible risk factors of acute leukemias, proved that genetic factors play a crucial role in leukemogenesis. Recent genetic association studies on cancer risk, have focused on the effects of single nucleotide polymorphisms in genes that regulate inflammation and tumor suppression such as chemokines and P450 cytochrome. Chemokines induce the motility of endothelial and tumor cells. CXCL12, a chemokine expressed in various tumors, binds to chemokine receptor 4 (CXCR4) and is considered to play an important role in tumor growth and invasion. The polymorphism rs1801157 of this gene have been investigated concerning the disease pathogenesis. Moreover, CYP1A1 gene belongs to family 1, subfamily 1A1 of cytochrome P450. CYP1A1 protein is a phase I xenobiotic metabolizing enzyme that activates the conversion of environmental chemicals into carcinogens. The above gene contains two important single nucleotide polymorphism, CYP1A1*2A (rs4646903) and CYP1A1*2C (rs1048943), which are associated with an increased risk of leukemia.
Aims: The study of single nucleotide polymorphisms rs1801157 of CXCL12 and CYP1A1*2C (rs1048943) in children with B-lineage ALL .
Methods: Thirty children with B- lineage ALL (19 boys, mean age 6.8 years) were included in the present study and 70 healthy individuals (20 children and 50 adults blood donors) as control group. Genomic DNA was isolated from peripheral blood of participants and was analyzed for the existence of polymorphisms rs1801157 of CXCL12, and CYP1A1*2C (rs1048943) with Polymerase Chain Reaction (PCR). The PCR products were digested with the restriction enzyme MsPI for CXCL12 and BsrDI for CYP1A1. Descriptive statistics and logistic regression analysis were used to examine for differences between children with ALL and controls.
Results: In the CXCL12 loci, the frequencies of AA, AG, and GG genotype were 3.45%, 93.1% and 3.45% in children with ALL, 13.3%, 60.0%, 26.7% in children control group and 4.17%, 45.83% and 50.0% in adult control group respectively. In the CYP1A1 loci, the frequencies of AA, AG, and GG genotype were 13.3%, 86.7% and 0% in children with ALL, 90.0%, 10.0%, 0% in children control group and 81.6%, 16.4% and 2.0% in adult control group respectively. No statistical significant differences in CXCL12 polymorphism were revealed between children with ALL and healthy groups using logistic regression analysis. Regarding CYP1A1 loci, we detected a positive association for the AG polymorphism and ALL [OR: 37.7 (95% CI: 10.81, 131.37), $p<0.001$ and OR: 58.5 (95% CI: 9.66, 354.12), $p<0.001$ using only the children's control group].
Summary/Conclusions: A higher frequency of CYP1A1 heterozygote allele was observed among children with ALL compared to controls, whereas no differences were observed regarding CXCL12 polymorphisms. Future studies in larger populations are needed in order to specify the role of the above polymorphism in childhood ALL.

INTRACHROMOSOMAL AMPLIFICATION OF CHROMOSOME 21 IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA; A RARE SUBTYPE

L. Vida[1,*], A. Burján[1], B. Horváth[1], L. Kereskai[1], G. Ottóffy[2], L. Tiszlavicz[3], D. Alpár[4], B. Kajtár[1]
[1]Pathology, [2]Pediatrics, University of Pécs, Pécs, [3]Pediatrics, University of

Szeged, Szeged, Hungary, [4]Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria

Background: Intrachromosomal amplification of chromosome 21 (iAMP21) defines a rare subtype of pediatric acute lymphoblastic leukemia (pALL) occurring in approximately 2-3% of cases. The patients are older (median age is 9 years), usually have low white blood cell counts and show high relapse risk with standard therapy. Thus, it has been proposed to include ALL with iAMP21 as a distinct entity in the WHO classification of hematological malignancies.
Aims: To assess the frequency as well as the clinicopathological and genetic characteristics of ALL with iAMP21 in one of the three national diagnostic centers of pALL in Hungary. We sought to determine additional genetic aberrations associated with this rare entity.
Methods: Between 2008-2016, 175 samples of pALL patients were tested with FISH for *BCR-ABL1*, *ETV6-RUNX1* and *MLL* translocations. When available, bone marrow karyotyping was used to verify the abnormal results. In one case with iAMP21, multiplex ligations-dependent probe amplification (MLPA) was used to verify the cytogenetic aberrations as well as to detect associated copy number alterations.
Results: Among the 175 samples screened with FISH, three showed evidence of iAMP21 (1.7%). Case 1 was a 16-year-old male who presented with thrombocytopenia and hepatosplenomegaly. Flow cytometry (FCM) showed common ALL phenotype with the expression of CD13 and CD33. FISH showed >10 *RUNX1* signals in clusters in leukemic blasts, while karyotyping demonstrated r(21) with 7q deletion and +X. The lesions were verified by MLPA, which additionally revealed biallelic *CDKN2B* and *RB1* deletions. The patient was treated with ALL-IC BFM 2002 standard risk protocol. Following remission, isolated meningeal relapse occurred, for which he received radiotherapy. The patient died with recurrent meningeal disease without bone marrow involvement after 52 months. Case 2 was an 11-year-old girl, who presented with symptoms suggesting osteomyelitis of the tibia with unremarkable blood count. MRI showed multiple lesions in vertebrae as well as meningeal involvement of the spinal cord. Bone marrow biopsy and biopsy of the left tibia showed diffuse infiltration of lymphoblasts with only 5% leukemic cells in bone marrow aspirates. FISH detected 6-8 copies of *RUNX1* in leukemic blasts, while karyotyping yielded only normal bone marrow cells. She was commenced on ALL-IC BFM 2002 standard risk and was later switched to high risk protocol. She is in complete remission after 14 months. Case 3 was an 11-year-old boy who presented with anemia and thrombocytopenia. FCM showed ALL with common phenotype with two populations; one being strong CD19+/CD66c+ and one with dim CD19+/CD66c-. FISH showed >10 *RUNX1* signals in clusters in 95% of cells, while 52% showed *BCR-ABL1* positivity. Bone marrow karyotyping yielded metaphases of poor quality (Figure 1).

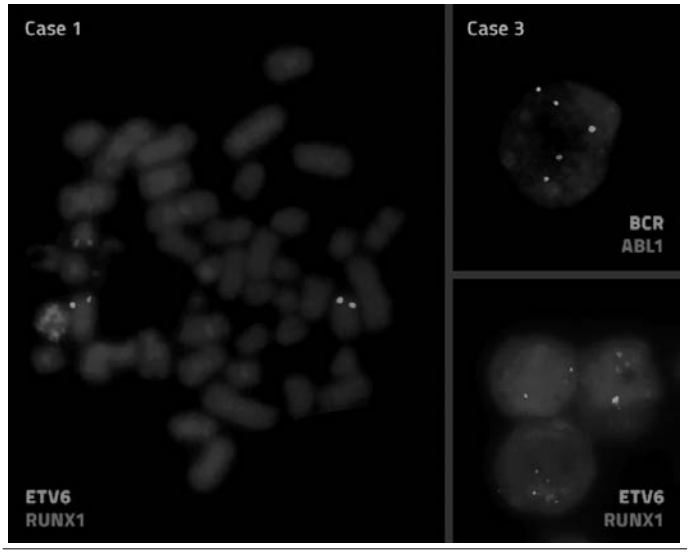

Figure 1.

Summary/Conclusions: ALL with iAMP21 is a rare subtype with distinct clinicopathological characteristics. Presenting with only mildly elevated WBC in older children is typical, relapses are frequent if standard risk chemotherapy is administered. Association with *BCR-ABL1* translocation is rare, having been reported so far in only 4 cases. Observing *BCR-ABL1* translocation in a subpopulation of leukemic cells is an intriguing phenomenon; it indicates that this translocation may occur as a secondary event even after leukemic transformation has commenced.

PB1628

HIGH RESOLUTION TECHNOLOGIES IN B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

A. Escudero[1,*], P. Carrasco[1], J. Nevado[1], M. Palomares[1], E. Vallespín[1], P. Lapunzina[1], L. Fernández[2], M. Vela[3], I. Gonzalo[1], B. González[4], D. Bueno[4], Á. del Pozo[1], A. Pérez-Martínez[4]
[1]INGEMM, Hospital Universitario la Paz, [2]Clinical Research, CNIO, [3]IdiPAZ, [4]Pediatric Hemato-Oncology, Hospital Universitario la Paz, Madrid, Spain

Background: B-cell acute lymphoblastic leukemia (B-ALL), the most common pediatric malignancy and main case of childhood cancer death, resulting from accumulation of genetic aberrations. Advances in our understanding of these aberrations is useful to improve disease classification, prognosis, therapeutic purposes, and to provide an overall understanding of the pathogenesis of the B-ALL.
Aims: Genomic characterization of childhood B-ALL.
Methods: We retrospectively examined bone marrow samples from 29 pediatric B-ALL using high resolution technology. We study copy number alteration (CNAs) and copy neutral loss of heterozygosity (CN-LOH) using Illumina CytoSNP-850K BeadChip in the Illumina HiScan platform. Analysis of more than 90 genes related with pediatric cancer was done using Next Generation Sequencing (NGS).
Results: Except for one, all patients showed copy number alterations. Losses were more common than gains. Whole and partial CN-LOH were observed in 12 cases. Only four recurrent genetic alterations were found: hyperdiploidy (44% of the cases), deletion of *CDKN2A/B* genes (22%), deletion of *PAX5* gene (16%) and deletion of *ETV6* (9%) gene. Several possible target genes were identified, including *SESN1, NME1* and *BMPR1B*, but additional studies are needed to confirm their implication in the disease. We identified high diversity of mutations 30 genes, 40% of all mutations are previously described in cancer patients. We found several mutations in Jak gene family in 5 patients that could have been the subject of therapeutic intervention with specific inhibitors of these kinases.
Summary/Conclusions: NGS and SNP arrays are powerful genetics tools capable of identifying a multitude of genetic alterations associated with B-ALL. The use of SNP arrays and NGS in clinical practice can help identify new prognostic alterations and develop individualized treatment plans for affected children.

Acute lymphoblastic leukemia - Clinical

PB1629

COMPLETE REMISSION WITH BLINATUMOMAB IN TWO PATIENTS WITH SKIN RELAPSED B-CELL ACUTE LEUKEMIA

H. Leroy[1,*], M.-L. Jullie[1], E. Forcade[1], G. Laboure[1], R. Tabrizi[1], P.-Y. Dumas[1], M. Robles[1], A. Chauvel[1], B. Vergier[1], N. Milpied[1], A. Pigneux[1], T. Leguay[1]
[1]CHU Bordeaux Haut lévèque, pessac, France

Background: Blinatumomab is a bispecific T cell–engager (BiTE) antibody (CD19/ CD3) indicated in relapsed/refractory B-cell Acute Lymphoid Leukemia (r/r ALL) (Topp *et al.*). Extra-medullary relapse is a rare event occurring in only 8% of the patients, of whom only 1.4% present a skin relapse which harbor a dismal prognosis (Gokbuget *et al.*).
Aims: Herein, we report the efficacy of Blinatumomab in two patients presenting with extra-medullary relapse of ALL.
Methods: The first patient (a 40-year-old man) was diagnosed a CD19+ Ph - B-ALL in 2009. He received a chemotherapy regimen according to the GRAALL protocol (Huguet *et al.*) until complete remission (CR). In 2015, he presented with a maculopapular rash of the right leg and the left flank, and two enlarged inguinal lymph nodes. Cutaneous relapse was attested by examination of skin biopsy specimen showing a blastic dermal infiltration harboring a CD10+, Tdt+ phénotype. The second patient was a 50-year-old male who presented, in 2016, a CD19+ B-ALL Ph- Ikaros- without central nervous system involvement. He obtained a first CR after GRAALL induction with negative MRD (IgH) but he relapsed 3 months later with a maculopapular rash of his chest. The skin biopsy revealed a blastic dermal infiltration. These two patients with skin relapse received salvage chemotherapy (COPRAALL 2007 regimen) *(*Domenech *et al.)*, with no efficacy (cutaneous blastic infiltrate). Both patients received one cycle of Blinatumomab from day 1 to day 28, at 28 µg per day, in an attempt to achieve CR before allogeneic stem cell transplantation, as previously described.
Results: At day 5 of Blinatumomab, an important non pruritic maculo-papular rash occurred in both patient, in the same area of the initial cutaneous involvement. Interestingly, it decreased after day 8. No new drug introduction or infection (bacterial, viral or parasitic) was documented in the days preceding or during Blinatumomab infusion. A skin biopsy performed at day 6 of Blinatumomab showed a more prominent dermal CD3+ lymphocytic infiltrate with a perivascular, but also a peri-nervous distribution (on the first patient's specimen only). Few lymphocytes marginated at the basement membrane and rare basal necrotic keratinocytes were also noted but without blast for the first, although few residual blastic cells were observed on the second's. One month later, another skin biopsy showed a CR without lymphocytic infiltrate. The medullar CR was confirmed at the molecular level (MRD negative). The first patient received allogenic stem cell transplantation (SCT) from a matched related donor one month later. He presented an acute and chronic GVHD, and is now in complete remission with a follow-up of 7 months. The second is still waiting for a SCT.
Summary/Conclusions: These observations confirm the strong efficacy of Blinatumomab in r/r B-ALL. We observed a T-cell dermal recruitment 6 days after Blinatumomab initiation clinically mimicking skin GVHD. However, we couldn't find specific histological features of GVHD, but only an "inflammatory dermatosis". Efficacy of Blinatumomab in relapsed B-ALL with cutaneous infiltration suggests promising activity in extra-medullary relapse. Further studies are required to confirm a Blinatumomab-based strategy in extra medullary relapsed B-ALL. This may provide a better understanding of how cytolytic synapses between T lymphocytes and intradermal blasts happen and the underlying homing mechanisms involved.

PB1630

A NOVEL METHOD FOR MINIMAL RESIDUAL DISEASE ANALYSIS IN PHILADELPHIA-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA: MODIFIED BIOMED-2 POLYMERASE CHAIN REACTION FOR IMMUNOGLOBULIN HEAVY CHAIN REARRANGEMENT

D. Katoh[1,*], M. Nakamura[1], M. Morita[1], H. Maruoka[2], A. Fujimoto[1], T. Yabushita[1], Y. Shimomura[1], Y. Ono[1], N. Hiramoto[3], S. Yoshioka[1], N. Yonetani[1], A. Matsushita[1], H. Hashimoto[3], T. Ishikawa[1]
[1]Hematology, [2]Clinical Laboratory, Kobe City Medical Center General Hospital, [3]Cell Therapy, Institute of Biomedical Research and Innovation, Kobe, Japan

Background: Recent studies have demonstrated the clinical importance of minimal residual disease (MRD) monitoring in adult acute lymphoblastic leukemia (ALL) as well as pediatric ALL. However, patient-specific polymerase chain reaction (PCR)-based MRD assessment, one of the most commonly recognized methods, is not widely used in clinical practice because it is expensive, time consuming, and technically difficult. Therefore, we modified the BIOMED-2 protocol, PCR for immunoglobulin heavy chain (IgH) rearrangement, to assess MRD in ALL easily and readily in our hospital.
Aims: The aim of this study was to examine the clinical utility of monitoring MRD by the modified BIOMED-2 PCR for IgH rearrangement in patients with Philadelphia-negative (Ph (-)) ALL.
Methods: We enrolled 54 patients diagnosed with Ph (-) ALL between 2006 and 2016 in our hospital. IgH rearrangement was detected in 35 patients using the standard BIOMED-2 PCR protocol. Patients who received palliative chemotherapy, never achieved remission (blasts <5%), or had no follow-up MRD data were excluded. Finally, data from 27 patients with Ph (-) ALL were analyzed. We assessed MRD with the modified BIOMED-2 PCR for IgH using bone marrow samples collected after each chemotherapy session. Patients' MRD statuses were classified as follows: Early MRD^{neg}, achievement of MRD negativity within 6 weeks after chemotherapy initiation; Late MRD^{neg}, achievement of MRD negativity more than 6 weeks after chemotherapy initiation; or MRD^{pos}, persistent MRD detection during chemotherapy. The endpoint was disease-free survival (DFS), calculated from the date of achieving remission.
Results: The median age was 38 years (16–73), and the median follow-up time was 47 months (4–106). There were 8, 14, and 5 patients with early MRD^{neg}, late MRD^{neg}, and MRD^{pos}, respectively. There were no differences in patient characteristics by bone marrow status, except for the duration to achieving remission (Table 1). There were significant differences in the 3-year DFS rates among patients with early MRD^{neg}, late MRD^{neg}, and MRD^{pos} (100% *vs* 72.9% *vs* 20%; p<0.001) (Figure 1). Patients undergoing transplantation had better prognosis than those receiving chemotherapy alone in the late MRD^{neg} group (100% *vs* 40%, p=0.028), whereas there was no difference in the early MRD^{neg} group (100% *vs* 100%, p=0.48).

Table 1. Patient characteristics by MRD status as assessed with the modified BIOMED-2 PCR for IgH protocol.

Factor	Total (n=27)	MRD^{pos} (n=5)	Late MRD^{neg} (n=14)	Early MRD^{neg} (n=8)	p-value
Sex, M/F	9/18	1/4	6/8	2/6	0.64
Age >50 years	10	1	6	3	0.87
WBC count risk*	4	1	3	0	0.37
Cytogenetic risk**	4	1	3	0	0.37
Transplantation	16	4	9	3	0.33
CR after 2 cycles***	2	2	0	0	0.03

* WBC risk: B >3 × 10^4/µL, T >10 × 10^4/µL.
** Cytogenetic risk: Hypodiploidy, complex karyotype, MLL rearrangement.
*** Achievement of remission after 2 cycles of chemotherapy.
MRD, minimal residual disease; PCR, polymerase chain reaction; IgH, immunoglobulin heavy chain; M, male; F, female; WBC, white blood cell; CR, complete remission.

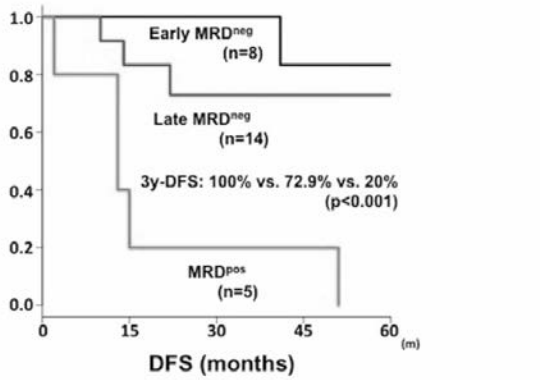

Figure 1. The status of minimal residual disease was associated with prognosis.

Summary/Conclusions: The modified BIOMED-2 PCR protocol is a highly accurate and reliable method of MRD assessment in adult ALL. It predicted treatment outcomes in adult Ph (-) ALL, and patients with late MRD^{neg} might derive a high survival benefit from allogeneic transplantation. Finally, the accuracy and reliability of the modified BIOMED-2 PCR for IgH were confirmed with a comparison to quantitative real-time PCR for BCR-ABL using samples from patients with Philadelphia-positive ALL (data not shown).

PB1631

SYSTEMATIC LITERATURE REVIEW OF PEGASPARGASE FOR THE TREATMENT OF NEWLY DIAGNOSED ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

E. Hooper[1,*], A. Wijatyk[1], D. Bollag[2]
[1]Shire, Cambridge, United States, [2]Shire, Zählerweg, Switzerland

Background: Asparaginase is a component of a multi-agent chemotherapy regimen and is now a cornerstone treatment for patients with acute lymphoblastic leukemia (ALL). Since 2006, pegaspargase (PEG-ASP) has been the gold standard asparaginase for the treatment of pediatric ALL as it offers equivalent efficacy to native *E. coli* L-asparaginase (native ASP), with less frequent dosing,

an IV administration option, and improved immunogenicity. Clinical outcomes in the adult ALL population are less well understood.

Aims: To assess the relative clinical benefit of PEG-ASP *vs* native ASP in 1st line treatment in newly diagnosed adult ALL patients in terms of event-free survival (EFS) and overall survival (OS). Safety outcomes were also examined.

Methods: A systematic literature search was conducted using a standardized search algorithm within the constraints of the National Library of Medicine database to identify available evidence for newly diagnosed patients treated with adult ALL protocols that use PEG-ASP or native ASP. Randomized, observational, and cohort studies were included, with the predefined clinical outcomes of event-free-survival (EFS) and overall survival (OS). Data was pooled with 95% confidence intervals (CIs) calculated using the logit transformation.

Results: A total of 30 studies were identified that met the pre-specified inclusion criteria, with 10 studies providing data for PEG-ASP and 23 studies for native ASP. The pooled estimate of 2-year EFS for adult ALL patients treated in 1st line with asparaginase was 48.0% (95% CI: [10.8; 85.2) for PEG-ASP and 66.0% (95% CI: [52.0; 77.0]) for native ASP.

The pooled estimate of 2-year OS for adult ALL patients was 62.8% (95% CI: [27.7; 97.9]) for PEG-ASP and 47.3% (95% CI: [8.5; 89.7]) for native ASP. Similarly, the pooled estimate of 5-year OS was 64.5% (95% CI: [61.5; 67.5%]) for PEG-ASP and 46.8% (95% CI: [33.6; 60.1]) for native ASP. In very high risk ALL patients, the pooled estimate of 5-year OS was 57.1% (95% CI: [52.4; 61.7%]) for PEG-ASP and 35.3% (95% CI: [21.7; 51.7]) for native ASP.

Findings for safety outcomes were consistent with product labeling for both asparaginases.

Summary/Conclusions: The systematic literature review highlights a positive clinical effectiveness profile for PEG-ASP in regards to EFS and OS in the treatment of newly diagnosed adult ALL patients with less frequent administration and similar safety profile as compared with native ASP.

PB1632

A COMPREHENSIVE ANALYSIS OF PATIENT- AND THERAPY-RELATED FACTORS AFFECTING THE TOXICITY OF PEGYLATED-ASPARAGINASE FOR THE TREATMENT OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

P. Minetto[1,*], N. Bisso[1], F. Guolo[1], M. Clavio[1], E. Coviello[1], D. Guardo[1], N. Di Felice[1], F. Canale[1], L. Manconi[1], F. Ballerini[1], M. Miglino[1], R. M. Lemoli[1], M. Gobbi[1]

[1]Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCSS AOU San Martino-IST, Genoa, Italy

Background: The application of pediatric regimens in the treatment of adult acute lymphoblastic leukemia (ALL) has led to a significant improvement in patients outcome. However, concerns about the feasibility of more intensive therapies and of the use of pegylated L-Asparaginase (PEG-ASP) in adult patients have emerged. Some patient-related risk factors as high BMI or hepatic steatosis have been already identified as risk factors, but few data are available on the synergic toxic effect from other concomitant drugs.

Aims: The aim of the present study was to evaluate the incidence of PEG-ASP related adverse events in a cohort of adult ALL patients in order to identify potential patient and therapy-related risk factors contributing to toxicity.

Methods: Since 2013, 21 adult ALL patients received PEG-ASP therapy in our institution. Median age was 44 (range 19-76); 12 patients were treated in frontline setting (7 according to a full pediatric protocol) whereas 9 patients received therapy for relapsed/refractory neoplasm. We retrospectively analyzed each single course which included PEG-ASP administration as an independent event, accounting 41 episodes. Patients' features (age, BMI, disease status) and concomitant therapies were accurately analyzed as factors potentially affecting PEG-ASP toxicity. The incidence of major thrombotic/bleeding complications and grade III/IV hepatic or pancreatic toxicity was analyzed; toxicity grading and management of PEG-ASP related complications were performed according to guidelines recently published by Stock *et al.*

Results: No grade III/IV pancreatic, thrombotic or hemorrhagic adverse events were recorded. A total of 8 episodes of grade III/IV hepatic toxicities were observed. In 3 cases, grade IV toxicity was observed. Those patients experienced unexplained severe weight gain and painful epathomegaly, a clinical picture resembling sinusoidal occlusive disease, ultrasonography showed acute liver steatosis. All 3 patients received concomitant therapy with idarubicin, vincristine and vancomycin. In univariate analysis, the incidence of grade III/IV hepatic toxicity was significantly higher when concomitant chemotherapy with at least 2 mg/sqm cumulative dose of vincristine (p 0.044, HR 4.75) or at least 16 mg/sqm cumulative dose of idarubicine (p 0.046, HR 1.45) were administered. Steroids therapy determined a borderline increase in toxicity risk (p 0.068, HR 1.688). No increase in toxicity was observed with any dosing of daunorubicin, cyclophosphamide, cytarabine, methotrexate and 6-mercaptopurine (Table 1). Among concomitant antibiotic therapies, vancomycin administration seemed to increase the incidence of grade III/IV hepato-toxicy (p 0.02, HR 1.863). No significant increase was observed with carbapenems and azoles (Table 1). Older age (>45), receiving PEG-ASP with active leukemia or a high BMI (>25) were not related with an increased incidence of grade III/IV hepatotoxicity (Table 1). Notably, none of the patients undergoing full pediatric induction (who received the highest doses of PEG-ASP), regardless of age (ranging from 21 to 55) experienced grade III/IV hepatotoxicity. A multivariate logistic regression analysis disclosed that concomitant administration of idarubicin, vincristine or vancomycin were independent predictors of grade III/IV hepatotoxicity (p 0.004, 0.027 and 0.042, respectively, Table 1).

Table 1.

Variables related to grade III/IV hepatic toxicity

	Grade III/IV hepatic toxicities [%]	HR	p [univariate]	p [multivariate]
Age >65 years	5/17 (29)	-	0.250	-
BMI >25	2/12 (17)	-	1.000	-
Higher PEG-ASP dose	8/29 (28)	-	0.250	-
Daunorubicin	4/12 (75)	-	0.690	-
Vincristine	7/29 (25)	4.75	0.044	0.027
Cyclophosphamide	5/31 (16)	-	0.698	-
Idarubicine	3/9 (50)	1.45	0.046	0.004
Cytarabine	1/15 (13)	-	0.219	-
6-Mercaptopurine	0/12 (0)	-	0.078	0.003
Methotrexate	0/7 (0)	-	0.399	-
Steroids	6/30 (27)	1.69	0.068	0.742
Vancomicine	4/7 (57)	1.86	0.020	0.042
Azoles antifungals	4/17 (24)	-	0.628	-
Carbapenemics	5/13 (39)	-	0.086	0.455
OVERALL	8/41 (20)	-	-	-

Summary/Conclusions: Our data show that the toxicity profile of PEG-ASP in adult patients is overall manageable. However, serious warnings emerge from our experience. Concomitant drugs and their timing of administration may play a crucial role in significantly contributing to PEG-ASP hepatic toxicity. In order to attempt to reduce toxicity, anthracyclines with shorter half-life, *i.e.* daunorubicin instead of idarubicin, should be used. A particular attention should be paid when administration of concomitant antibiotic therapy is required.

PB1633

COST OF CARE FOR ADULT PATIENTS WITH RELAPSED ACUTE LYMPHOBLASTIC LEUKEMIA WITH AND WITHOUT HEMATOPOIETIC STEM CELL TRANSPLANT IN GERMANY

Y. Su[1,*], S. Schmitter[2], A. Navarro[3], L. Mayerhoff[3], S. Prieur[3], M. Lehne[3], F.R. Loberiza[1]

[1]Pfizer Inc., New York, United States, [2]Pfizer Deutschland GmbH, [3]Elsevier Health Analytics, Berlin, Germany

Background: Adult ALL is a rare but frequently fatal disease. Many patients who respond to initial therapy experience a relapse. For relapsed ALL (rALL), hematopoietic stem cell transplant (HSCT) is a potentially curative treatment option. HSCT is associated with added costs, however, which could impact overall healthcare budget.

Aims: This retrospective observational study aims to determine the cost of care and the impact of HSCT on total cost for adult rALL patients from a German payers' perspective.

Methods: A German claims database with a representative sample of approximately 7 million individuals insured within the German statutory health insurance and continuously observable over a period of 6 years was used as data source. From these data, adult patients (18 years and older) with a new diagnosis of ALL (ICD-10-GM code: C91.0*) between January 1, 2011 and December 31, 2015 and a relapse after remission to initial treatment were identified. Mean health care cost per patient per quarter, the smallest unit of time available in the database, was determined by whether or not patients had an HSCT after relapse. Costs were considered from the perspective of the German statutory health insurance and included costs for prescription medicine as well as outpatient and inpatient healthcare encounters.

Results: Of the total 116 incident adult ALL patients identified, 29 (25%) were determined to have had a relapse and 11 underwent HSCT after relapse (38%). Patients with an HSCT appear to incur higher cost than those without HSCT in each of the quarters after relapse was diagnosed (Table 1), with the highest in the first quarter after relapse, but decreasing in subsequent quarters. Inpatient cost accounted for the majority of the cost for the first three quarters for both HSCT and non-HSCT patients, but more for HSCT patients. The number of patients in the HSCT cohort remained relatively stable, while the non-HSCT cohort had only half the patients left by the third quarter post relapse.

Table 1. Costs in € per patient (with and without HSCT) by quarter after relapse

Patient group	Index quarter (relapse)			Q1			Q2			Q3		
	N	mean	% Inpatient cost	N	mean	% Inpatient cost	N	mean	% Inpatient cost	N	mean	% Inpatient cost
rALL without HSCT	18	34,616	84%	18	23,228	83%	11	10,762	61%	9	11,194	73%
rALL with HSCT	11	38,057	79%	10	54,559	88%	9	25,972	65%	9	27,055	88%
Total	29	35,921	82%	28	34,417	86%	20	17,606	64%	18	19,125	84%

Summary/Conclusions: The results of this study inform the magnitude of cost in Germany associated with adult rALL patients with or without an HSCT after relapse. The cost estimates provide a benchmark against which new treatment options for rALL can be compared. For future studies, it would be important to determine the magnitude of benefit such as long-term survival and other health consequences associated with HSCT as well.

PB1634

RETROSPECTIVE STUDY OF ADULT ALL IN MEXICO CITY: FIRST REPORT OF THE WORKING GROUP ON ACUTE LEUKEMIA

E. Crespo-Solís[1,*], K. Espinosa-Bautista[2], M. Alvarado-Ibarra[3], E. Rozen-Fuller[4], F. Pérez-Rocha[5], L. A. Meillón-García[5], C. Nava-Gómez[2], M. Ortiz-Zepeda[3], J. L. Alvarez-Vera[3], C. O. Ramos-Peñafiel[4], S. Rodríguez-Rodríguez[6], A. Pomerantz-Okon[6], R. Demichelis-Gómez[6]
[1]Department of Hematology and Oncology, Hospital Regional de Alta Especialidad Ciudad Victoria, Victoria, [2]Department of Hematology and Oncology, Instituto Nacional de Cancerología, [3]Department of Hematology and Oncology, Centro Médico Nacional 20 de Noviembre, ISSSTE, [4]Department of Hematology and Oncology, Hospital General de México, [5]Department of Hematology and Oncology, Centro Médico Nacional Siglo XXI, IMSS, [6]Department of Hematology and Oncology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Background: The prognosis of adult acute lymphoblastic leukemia (ALL) is dire, with a long-term survival of 40-50%. This disease entity is probably more frequent in the Latino population. Several studies have reported a worse prognosis in Hispanics with ALL as well as a greater incidence of the Ph-like genetic signature; however, the data is inconclusive in the Mexican population and there are no existing large multicenter series of ALL patients in Mexico that analyze survival.
Aims: The aim of this study was to describe the incidence, clinical and biologic characteristics as well as the survival of ALL patients in 5 referral hospitals in Mexico City.
Methods: A working group known as the *Grupo de Trabajo de Leucemia Aguda (GTLA)*, was created as a result of an initiative of the Mexican Group for the Study of Hematology *(Agrupación Mexicana para el Estudio de le Hematología*) to promote acute leukemia research in Mexico. This is the first report of the GTLA which includes 5 referral hospitals in Mexico City. A retrospective, multicenter, descriptive study of adult ALL patients treated between 2009 and 2015 was conducted.
Results: We included 559 adults in 5 centers in Mexico City. Their median age was 28 years (14-81): adolescents and young adults (AYA) 67.3%; adults 24.7% and elderly adults 8.1%. Tumor lysis syndrome was detected in 9.8% of all cases. Cytogenetic information was unavailable in 45% of cases due to lack of access or growth in metaphase. Among cases that could be analyzed, a normal karyotype was the most frequent (70.5%), followed by Ph+ (16.7%). Patients were considered high-risk in 52.1% cases. The most frequently used drug protocol was Hyper-CVAD, in 47% of cases. Complete remission (CR) was achieved in 67.1% of patients, and 18% required a second cycle for CR, while 13% were primarily refractory. A mortality rate during induction was registered as 10.6%, and there were 11.4% deaths while in CR. Among patients in CR, 59.1% relapsed. At the time of analysis, 26.7% of patients were alive, with a median OS of 12.97 months and a DFS of 16 months. Only 5.7% were able to receive an allogeneic hematopoietic progenitor cell transplant (AlloHPCT). OS at 3 years was 22.1% and by age group: AYA 25.7%, adults 17.4% and elderly adults 0% (p=0.0001). On multivariate analysis, significant risk factors for OS were the age group, ECOG, the presence of the tumor lysis syndrome and liver function test abnormalities while protective factors included early CR and an AlloHPCT.
Summary/Conclusions: Outcomes are poor in adult ALL patients treated in these referral centers in Mexico City. This may be explained by the high incidence of AYA patients and the low frequency with which they are treated with regimens containing L-asparaginase. The incidence of the Philadelphia chromosome is lower than reported, which could be due to a real difference between populations or due to aspects related to cytogenetic techniques. Based on these results, the GTLA´s objectives will be: to standardize diagnostic testing (immunophenotype and cytogenetics), improve early CR rates, standardize support care to decrease deaths during induction as well as treatment -related deaths, and increase the percentage of patients treated with AlloHPCT. Studies to determine the prevalence of the Ph-like genetic signature will be of great relevance in our population.

PB1635

IMPACT OF DISEASE STATUS ON OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH REFRACTORY AND RELAPSED ACUTE LYMPHOBLASTIC LEUKEMI

J. Cao[1], X. Zhu[1], A. Sun[1], H. Qiu[1], Z. Jin[1], M. Miao[1], D. Wu[1,2], X. Tang[1,2,*]
[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, [2]Institute of Blood and Marrow Transplantation,Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Refractory or relapse remains a major obstacle in improving outcomes of patients with acute lymphoblastic leukemia (ALL). And allogeneic hematopoietic stem cell transplant (allo-HSCT) was the only curative treatment option for these patients. However, whether an allo-HSCT was performed in status of advanced stage or in setting of remission after salvage chemotherapy, there is no standard of care.
Aims: To evaluate the impact of disease status on the outcomes of allo-HSCT in the treatment of patients with refractory and relapsed ALL.
Methods: 52 patients with refractory and relapsed ALL, including 19 cases in advanced stage (nonremission, NR) and 33 cases in more than or equal to second complete remission(≥CR2), received allo-HSCT after myeloablative conditioning regimen in our department.
Results: 51 patients engrafted successfully. The transplantation-related mortality (TRM) rate of NR and ≥CR2 was 10.5% *vs* 12.1% (P=0.815). The incidence of aGVHD was 52.6% *vs* 57.6% (P=0.730), including 42.1% *vs* 33.3% (P=0.527) with mild (grade I-II) and 10.5% *vs* 24.3% (P=0.399) with severe (grade III-IV) aGVHD. The incidence of cGVHD was similar also(41.6% *vs* 57.9% ,P=0.660). With a median follow-up of 12(1.8-44.5) months, the cumulative relapse rate of NR and ≥CR2 was 47% *vs* 34.3%□P=0.425) respectively. The estimated 2 year overall survival (OS) and 2 year leukemia-free survival (LFS) rate were 42.6% *vs* 45.7% (P=0.487) and 46.3% *vs* 46.2% (P=0.571) respectively. Multivariate Analysis results showed that cGVHD was independent favorable risk factor for OS and LFS of R/R ALL□For relapsed patients, OS was significantly better with first CR duration>6 month and time to transplant≤2 months.
Summary/Conclusions: Allo-HSCT is an effective salvage treatment option for patients with refractory and relapsed ALL. Our retrospective analysis showed that R/R ALL with different status prior transplant had similar outcome post transplantation.

PB1636

THE FREQUENCY AND PROGNOSTIC SIGNIFICANCE OF IKZF1 DELETIONS IN ADULT PH-POSITIVE AND PH-NEGATIVE B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED IN RUSSIAN ACUTE LYMPHOBLASTIC LEUKEMIA STUDIES.

G. Baskhaeva[1,*], B. Biderman[1], O. Gavrilina[1], K. Zarubina[1], I. Lukyanova[1], E. Stepanova[1], V. Troitskaya[1], A. Sudarikov[1], E. Parovichnikova[1]
[1]Hematological Research Center under the Ministry of Health, Moscow, Russian Federation

Background: The incidence of IKZF1 gene deletions is approximately 20% in adult patients with BCR-ABL1- negative B-cell ALL and 70–80% in BCR-ABL1-positive ALL. These mutations are associated with poor prognosis in patients with Ph-negative ALL, but not in patients with Ph-positive ALL, suggesting that IKZF1 deletions may be more prognostically valuable in patients with Ph-negative ALL.
Aims: To evaluate the frequency and prognostic impact of mutation status of IKZF1 in patients with d*e novo* BCR-ABL1-negative and BCR-ABL1-positive B-cell acute lymphoblastic leukemia.
Methods: The study included 36 adult patients (median age 27, range 17-56; m:f=15:21) with newly diagnosed BCR-ABL1- neg B-cell ALL and 15 patients (median age 34 years, range 22–68; m:f=6:9) with BCR-ABL1- pos B-cell ALL, who were enrolled in Russian acute lymphoblastic leukemia (RALL) - 2009 [ClinicalTrials.gov public site; NCT01193933] and RALL-2012 protocols since Feb 2010 till Sep 2016 and Aug 2009 till Feb 2017, respectively.
Intragenic deletions of IKZF1 were detected using breakpoint-specific fluorescent multiplex polymerase chain reaction according to the procedure described by [Aurelie Caye et al, Haematologica, 2013]. DNA for PCR was extracted from leukemia cells of frozen bone marrow samples.
Results: The IKZF1 deletions were detected in 7 (47%) of 15 patients with BCR-ABL1- pos ALL (3 cases with del 4-7 (43%), 2 – del 2-7 (28%), 1 – del 2a-8 and 1 – del 4-8 (14%)). The median follow-up time in 15 patients was 18 months (range: 4-79 month). Five patients died (33%) after relapse or progression of the disease, and 10 patients are alive. Overall survival (OS) in BCR-ABL1 - pos B-cell ALL patients with IKZF1 mutations and without was 37,5% and 57,1% (p=0,77), relapse - free survival (RFS) - 25% and 33,3% (p=0,88), respectively. In patients with BCR-ABL1- neg ALL the IKZF1 deletions were revealed in 8 (22%) of 36 patients (4 cases with del 4-7 (50%), 2 - del 2-7 (25%), 1 – del of 2-8 (12,5%) and in 1 patient all types of deletions were determined (del 4-7, del 4-8, del 2-7, del 2-8)). The median follow-up time in 36 patients was 22 months (range: 0,5-84 month). 4 patients died of the disease (11%) and 2 of infections, 30 patients are alive. OS for patients with BCR-ABL1- neg ALL with IKZF1 mutations and without was 100% and 60,2% (p=0,77), RFS - 75% and 40,2% (p=0,74), respectively. (Figure 1).
Summary/Conclusions: The frequency of IKZF1 gene deletions in patients with BCR-ABL1- pos and with BCR-ABL1- neg ALL was 47% and 22%, respectively. IKZF1 mutations seemed to be of poor prognosis for BCR-ABL1-

pos ALL and, on the contrary, more favorable for BCR-ABL1- neg ALL, though not statistically significant. Having or not IKZF1 mutations, all BCR-ABL1-pos ALL patients are candidates for allogeneic hematopoietic stem cell transplantation (allo-HSCT). Regarding BCR-ABL1-neg ALL: though the group of patients is small, we can suggest that IKZF1 mutation did not appear to influence survival due to different chemotherapy principal in RALL – 2009 – non-intensive but not-interruptive therapy with low numbers of HSCT.

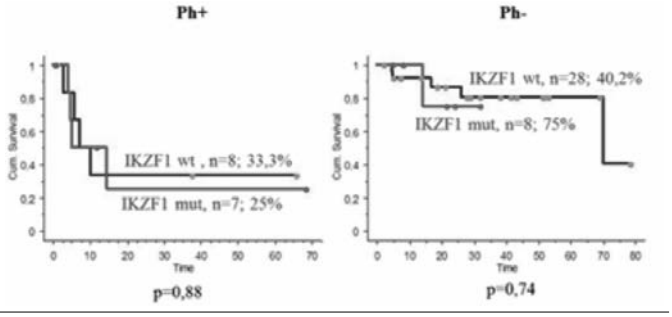

Figure 1. Relapse-free survival.

PB1637

GMALL BASED PROTOCOL, USING NATIVE E. COLI L-ASPARAGINASE, IMPROVES SURVIVAL OF ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA IN BRAZIL

I. Arcuri[1,*], J. Ramires[1], Y. Gonzaga[1], R. Dal Bello[1], B. Gomes[1], J. Dobbin[1], L. Arcuri[1]
[1]Instituto Nacional de Câncer, Rio de Janeiro, Brazil

Background: Despite being the most common childhood cancer, nearly one half of ALL cases occurs in adults. Recently, it has been suggested that more intensive protocols may improve survival in adolescents and young adults (AYA).
Aims: Compare results of patients treated with BFM-based protocol to those patients treated with GMALL-based protocol, in a developing country.
Methods: This is a single center retrospective study which included all newly diagnosed adult ALL patients admitted between May/2012 and October/2016. Initially, patients aged 18-39 years (AYA group) were treated with BFM ALL 2009-based protocol and those aged 40-59 years were treated with GMALL 2003-based protocol. Since September 2013, because of high toxicity, only patients under 30 years were elegible for BFM-based treatment. Major adaptations were: (1) native *E. coli* l-asparaginase was substituted for peg-asparaginase, and (2) GMALL irradiation therapy was postponed to maintenance phase. *BCR/ABL1* positive patients received standard chemotherapy plus Imatinib. Negative MRD was defined as <0,01% by flow cytometry. Overall survival was estimated by Kaplan-Meier method. Competing risk analysis was carried out for cumulative incidence of death in CR1 or not in CR1. This study was approved by local Ethics Committee.
Results: Thirty five patients were included, 21 of them started BFM-based treatment and 14 started GMALL-based protocol. During the first three months, 7 patients migrated from BFM to GMALL-based treatment because of toxicity and were analyzed separately. Median age was 21years (18-38) for BFM-based group, 44 years (30-57) for GMALL-based, and 33 years (21-38) for de-escalated. Male predominance was observed (71%), not different between groups. T-phenotype was more frequent than expected, representing 50% of BFM-based, 50% of GMALL-based and 29% of de-escalated groups. *BCR/ABL1* was detected in 14% of BFM-based, 23% of GMALL-based and 14% of de-escalated groups (p=0,85). Seven patients (2 BFM and 5 GMALL) underwent allogeneic stem cell transplantation in first remission. Of all 35 patients, 31 achieved complete remission after first induction phase. With median follow-up of 18 months, 1-year overall survival (OS) was 60% for all patients (39% for BFM-based, 75% for GMALL-based and 86% for de-escalated groups – p=0,04; BFM-based *versus* other protocols). Cumulative incidence (CI) of death in first complete remission (CR1) at 12 months was 18%, not different between groups. CI of death at 12 months in non-CR1 (relapsed or refractory) patients was 39% for BFM-based, 7% for GMALL-based and 0% for de-escalated groups – BFM-based *versus* other HR 2,6; p 0,13. Among 31 patients who achieved CR1, MRD data was available for 26 (74%) of these at the end of first induction. OS at 18 months for CR1 patients with negative MDR after first induction was 74%, compared to 52% in MRD+ (Figure 1).
Summary/Conclusions: Our results show that GMALL-based protocol yields good overall survival in adults ALL patients in a low income country, despite major adaptations. On the other hand, overall survival of AYA patients treated with BFM-based protocol was surprisingly poor, specially because of ineffective disease control. This finding may be related to several aspects: socioeconomic impairment, inadequate supportive care for more intense therapies and ineffective cancer care network. Future prospective studies should focus on this issues.

PB1638

THE INVESTIGATION OF RELATIONSHIP BETWEEN COL1A1 AND FOK1 GENE POLYMORPHISMS AND DEVELOPMENT OF TREATMENT-RELATED SKELETAL COMPLICATIONS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

M. Erdem[1], Ö. Tüfekçi[1], S. Kızıldağ[2], S. Yılmaz Bengoa[1,*], D. Kızmazoğlu[1], B. Eroğlu Filibeli[3], H. Ören[1]
[1]Pediatric Hematology, [2]Medical Biology and Medical Genetics, [3]Pediatrics, Dokuz Eylül University, İzmir, Turkey

Background: Cure rates for childhood acute lymphoblastic leukemia (ALL) have approached 90% with therapeutic advances over the last several decades. Many treatment related long-term complications including impaired physical growth, neurocognitive dysfunction, emotional and occupational di□culties, cardiac abnormalities, hypertension, secondary neoplasms, decreased bone mineral density (BMD) and osteonecrosis have been observed as the number of survivors increased. Bone infiltration of leukemic cells, corticosteroids exposure, poor nutrition, low vitamin D levels, poor muscle mass, genetic predispositions contribute to the development or worsening of bone pathology during therapy that may result in osteoporosis, fracture and osteonecrosis.
Aims: In this study, we aimed to investigate whether vitamin D receptor and collagen protein gene polymorphisms, which are important in bone mineral and matrix formation, have effects on bone turnover in patients with ALL.
Methods: Fifty children with ALL who were diagnosed and treated with BFM-95 protocol (25 girls, 25 boys) between 1998-2008 and 96 healty children at Dokuz Eylül University Medical School were enrolled in this study. Polymorphisms of vitamin D receptor (VDR) *Fok1* gene and the collagen *Col1A1* gene were studied from peripheral blood samples of the patients that were collected before initiation of chemotherapy protocol. After genomic DNA extraction, VDR *Fok1* gene and colloidal *Col1A1* gene polymorphisms were analyzed by polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP). The data including age, sex, leukemia risk group, presence or absence of relapse were all noted. Bone marrow density and markers of bone metabolism including serum calcium, phosphorus, serum alkaline phosphatase, parathyroid hormone and 25-OH D vitamin levels were all screened before initiation of maintenance treatment.
Results: The distribution of *Fok1* and *Col1A1* gene polymorphisms was similar both in the patient group and healthy control group. The frequency of gene polymorhisms in the patient group were 8% ff, 46%Ff and 46%FF for the *Fok1* genotype and 62%GG, 26%GT and 12%TT for the *Col1A1* genotype. Out of 50 patients, 16 (32%) patients were found to have skeletal diseases like osteopenia (16%), osteoporosis (12%) and osteonecrosis (8%). The *Fok1* genotype and *Col1A1* genotype polymorhisms were similar in both group of patients with or without skeletal diseases. The frequency of osteopenia was signicanly higher in the male group (p=0.049) and the frequency of osteonecrosis was signicanly higher in patients older than 10 years old (p=0.001). There was no significant association between *Fok1* and *Col1A1* gene polymorphisms and leukemia subtype, risk group or relapse rate.
Summary/Conclusions: It has recently become more important to prevent treatment-related complications that we see as a consequence of high cure rates in ALL. In this context we have investigated whether there is a relationship between gene polymorhisms and treatment related skeletal diseases like

osteopenia, osteoporosis and osteonecrosis. We haven't detected a significant association between *Fok1* and *Col1A1* gene polymorphisms and frequency of skeletal complications. Studies investigating the possible underlying genetic susceptibilites to certain complications are important not only for better management of complications but also for development of new individual patient-specific treatment modalities.

PB1639

OUTCOME OF ADOLESCENTS AND YOUNG ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH PEDIATRIC PROTOCOL: MONOCENTRIC STUDY

I. Frikha[1,*], M. Medhaffer[1], S. Hdijji[1], R. Kharrat[1], M. Chaari[2], O. Kassar[1], M. Ghorbel[1], H. Bellaaj[1], I. Ben Amor[1], F. Kallel[2], C. Kallel[3], M. Elloumi[1]
[1]Hematology, [2]Laboratory of Hematology, Hedi Chaker Hospital, Sfax, Tunisia, [3]Laboratory of Hematology, Habib Bourguiba Hospital, Sfax, Tunisia

Background: Several retrospective studies have confirmed that adolescents and young adults (AyA) with acute lymphoblastic leukemia(ALL) treated with pediatric protocols have better outcomes than similarly aged patients treated with adult protocols.
Aims: We reported results and feasibility of a pediatric-based protocol (EORTC 58951) in adolescents and young adults.
Methods: From January 2000 to December 2015, 72 patients aged 16 to 30 years with newly diagnosed ALL were treated, in the department of clinical hematology of Hedi Chaker Hospital, according to the pediatric protocol EORTC 58951. Further leukemia characteristics (Sex, White Blood cell count, Blasts phenotype, Cytogenetic results), we studied the protocol results: response to prophase), risk group stratification (average: AR1 and AR2, very high: VHR), remission rate, death rate, relapse rate and 5 years survivals (overall OS and event free EFS).
Results: Seventy two AyA ALL were treated with the pediatric protocol. The patients were 45 males and 27 females (SR=1.66). A WBC>100 G/l was noted in 32%. A T blast phenotype was noted in 53% of cases. Twenty two patients (30%) were PPR. Nine patients (13%) were treated according AR1 arm, 39 patients (54%) according AR2 arm and 24 patients (33%) according VHR arm induction. CR rate was 87% after one course and 94% after 2 courses. Induction death was noted in 3% and post-induction death was noted in 13%. Twenty four patients treated with VHR arm protocol were eligible for allogenic stem-cell transplantation (SCT), among them 15 patients had a familial donor and 10 patients were allograft (42%) and only 4 patients still in CR (2 patients died by GVH and 4 patients relapsed). Relapse was observed in 22 patients (32%), among them 12 during the first year of treatment. The median follow up was 101 months (8,4 years). The five years OS and EFS were respectively 50 and 50.4%.
Summary/Conclusions: The results of this pediatric based study show that response to therapy and prognostic in adolescent and young adults were better than those treated with adult protocols and tolerability of chemotherapy is acceptable. However OS and EFS, better than adult ALL treated by adult protocol (OS= 14%, EFS=14%: local study) was not satisfactory because the high toxic mortality rate.

PB1640

ASSESSMENT OF DEPRESSION AND SELF-CONCEPTION IN CHILDREN WITH ALL-TREATMENT

G. Aydogan[1,*], N. Kavcik[1], F. Akici[1], Z. Salcioglu[1], H. Sen[1], N. Ozdemir[1], C. Bayram[1], A. Aycicek[1]
[1]Pediatric Hematology, Kanuni Sultan Suleyman Education And Research Hospital, Istanbul, Turkey

Background: Leukemia is the most prevalent pediatric malignancy with acute lymphoblastic leukemia (ALL) being the most common accounting for 75% of leukemia cases with about 2400 newly diagnosed children each year worldwide. Treatment of ALL requires long course chemotherapy ranging up to 48 months with 20% possibility of relapse. Affected children receive in-patient treatment at the clinic for nearly six months for leukemia and related complications. The diagnosis of childhood leukemia and its stressful treatment, not only adversely impact the physical and psychological health of the children with leukemia, but also impose heavy psychological burden on their parent.
Aims: The study aimed to determine prevalance of condition of depression and self conception of children with leukemia and compare with healty children.
Methods: The study was conducted in 24 voluntary children with leukemia and 25 healthy children aged 9-16 years. Children with leukemia were evaluated at the time of diagnosis, end of induction treatment and end of consolidation treatment, just before the maintenence treatment, respectively. Psychological data including depression and low self-concept were assessed by Child Depression Scale and Piers Harris Self-Cocept Scale. The changes in psychological conditions due to long stay at the hospital were investigated. Demographic data included age, sex, school achievement, parents education, socioeconomic condition, loss of first degree relatives.
Results: The prevalance of depressive disorder in children with leukemia at the end of induction and at the end of consolidation treatment were significantly increased. Self-Concept Scales were found lower in these patients.
Summary/Conclusions: The children with ALL receive long course chemotherapy and become distanced from their family, school and milieu and as a result, these patients are vulnarable to psychological problems. They are more depressive and have lower self-conception comparing to healthy children. It is important to provide psychological support to these children in addition to their chemotherapy.

PB1641

SEVERE PSYCHIATRIC DISTURBANCES DURING THERAPY IN PEDIATRIC ALL

C. Tsipou[1,*], N. Tourkantoni[1], A. Kattamis[1]
[1]Hematology-Oncology Unit, 1st Department of Pediatrics, "Aghia Sofia" Children's Hospital, University of Athens, Athens, Greece

Background: Psychiatric disturbances are not uncommon in patients with cancer. Their pathogenetic mechanisms are variable and comprise consequences of the therapy, underlying disease, as well as personality characteristics. These disturbances are frequently associated with the use of corticosteroids, which is an essential component of the treatment for children and adolescents with Acute Lymphoblastic Leukemia (ALL).
Aims: This study aimed to investigate the incidence of severe psychiatric disturbances in patients treated for childhood ALL.
Methods: We report the results of a retrospective analysis of the incidence of severe psychiatric disturbances, defined as behavioral and psychological changes which lead to dangerous or erratic behaviors requiring use of psychiatric medications, in patients treated for childhood ALL. All patients were treated in a single institution and followed the same chemotherapeutic protocol, according to which, corticosteroids are administered initially during the "induction" phase and then in multiple subsequent pulses.
Results: Seventy patients (mean age:4.04 years old, range:1-16) were treated for ALL during the 4 years of the observation period. During that period, 9 (12.8%) children (6 boys, 3 girls) of mean age 12.3 years old (range: 10-15) experienced psychiatric - neurological symptoms and/or mental disorders, which included major depressive disorder, withdrawal, first psychotic episode, disorientation, visual hallucinations, mood swings and behavioral outbursts. The majority of the patients (8 patients, 6 at the Intermediate Risk group and 2 at the High Risk group) experienced disturbances during the reinduction phase, while treated with dexamethasone at 10 mg/m2 for 21 days. Two patients of the High Risk group presented with behavioral effects one during the second HR2 block. Patients who had symptoms of major depression were treated with either fluoxetine, or/and risperidone, or/ and escitalopram for a period of time ranging of 5 days to 6 months. One patient experienced a psychotic episode during reinduction (Prot.II,phase 2) with aggression and violence towards others and had to be treated immediately with intramuscularly haloperidol and diazepam. All of our patients are alive and in remission, 7 off therapy for a period of 3 years, and 2 receiving maintenance therapy. Statistical analysis showed that severe psychiatric disturbances were observed more frequently in older patients and they were more common with the administration of dexamethasone than with prednisolone.
Summary/Conclusions: Severe psychiatric disturbances are not infrequent in children and adolescents receiving treatment for ALL. Awareness of this complication, appropriate parental education for identifying early signs, and prompt therapeutic interventions are essential for optimal outcome. Further studies are required for identifying patients at risk and best use of chemotherapeutic agents and of dexamethasone.

PB1642

INCIDENCE, SEVERITY AND RISK FACTORS FOR NEUROLOGIC COMPLICATIONS ASSOCIATED WITH L ASPARAGINASE TREATMENT IN PAEDIATRIC PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA

G.M. Safta[1,*], C.G. Zaharia[1], A.M. Bica[1], L.E. Radu[1], A.N. Serbanica[1], A.D. Beldiman[1], T. Iuga[1], M. Asan[1], C. Nicolae[1], O. M. Rizea[1], A. Colita[1]
[1]Fundeni Clinical Institute, Bucharest, Romania

Background: Combined chemotherapy increased over time cure rate in patients with acute lymphoblastic leukemia (ALL). Among other things, one of the direct adverse effects of chemotherapy is affecting hemostasis inducing thrombosis or bleeding. Hemostasis can also be affected indirectly by the appearance of infections secondary immunosuppression. It has been found that L Asparaginase induces thrombotic events by reducing antithrombin III, protein C, protein S and by inducing endothelial damage. Thrombotic events may result as a direct effect of the disease, may be the effect of chemotherapy or may be related with prothrombotic status of the patient.
Aims: To evaluate incidence and severity of thrombotic or bleeding events in paediatric patients with ALL during chemotherapy.
Methods: We considered all patients hospitalized for ALL in the Pediatrics

Department of Clinical Institute Fundeni during 2010-2017 and received chemotherapy according to protocol ALL BFM 1995 and ALL BFM 2002, established after framing in the risk group.
Results: Over a period of 8 years in our department 280 patients with ALL received L-asparaginase in the induction phase. Neurological manifestation suggestive for bleeding or thrombotic events occurred in 9/280 (3,21%) patients. 2 patients were treated according protocol ALL BFM 1995 and 7 patients were treated according to protocol ALL BFM 2002. M/F ratio was 4/5. Patients had at diagnosis between 3 and 15 years (median age 9 years). All patients had thrombotic events after starting administration of L Asparaginase during induction. Most had clinical symptoms after the fourth dose of L Asparaginase. Clinical manifestations were accompanied by hypofibrinogenemia (<100 mg/dl) especially in patients who experienced bleeding. The patients who experienced thrombosis had decreased levels of antithrombin III, protein C and increased D dimer levels. The diagnosis of cerebral venous sinus thrombosis (CVST) is typically based on clinical suspicion and imaging confirmation. At 5 of these patients neuroimaging test (CT and MR imaging) documented CVST after developing neurological symptoms; one of the patients suffered major complication (extended brain injury) and died. All patients with ALL and thrombotic events received low-molecular weight heparin (LMWH) for 3 to 6 months. A follow-up CT or MRI at 3 to 6 months after diagnosis was made to assess for recanalization of the occluded cortical vein/sinuses. Survival in the patients with CVST was 84.61%. 1 patient with ALL and hemostasis alteration had intracerebral hemorrhage (ICH) with rapid progressive neurological deterioration to death. 1 patient had pulmonary embolism associated with clotting disorders and severe sepsis and he died. 2 patients had clinical manifestation (headache, confusion and seizures) and clotting disorders (decreased levels of antithrombin III, protein C, fibrinogen and increased D dimer levels), but with normal brain imaging. Survival in the cohort was 77,7%.
Summary/Conclusions: Thrombotic events have occured in all patients during induction. Clinical manifestation were depending on location, size and duration of thrombosis, from headaches, seizures or focal neurological deficits. Severe sepsis association was an additionally risk factor for thrombotic and bleeding events in patients with ALL. Screening for genetic prothrombotic defects diagnosis prior to initiating chemotherapy may represent a way to reduce thrombotic or bleeding events and appropriate management of hemostasis disorders that occur during the treatment.

PB1643

INCIDENCE AND SURVIVAL OF CHILDHOOD LEUKEMIA IN ARMENIA: A POPULATION-BASED ANALYSIS

M. Tatulyan[1,*], S. Daghbashyan[1], L. Krmoyan[1], A. Zakharyan[1], L. Vagharshakyan[1], L. Sahakyan[1]
[1]pediatric hematology/oncology department, Hematology Center after prof. Yeolyan, Yerevan, Armenia

Background: Leukaemia is the most common cancer in children. Childhood leukemia incidence and survival varies globally, and this could be associated with environmental risk factors, genetics, and improvement in diagnosis and treatment. Armenia is considered to be a mono ethnic nation.
Aims: We aimed to quantify the incidence of and mortality from acute leukaemias among children population in Armenia and their variation with gender, age, year of diagnosis.
Methods: In this work we included children diagnosed with de novo acute leukaemia, 0–18 years of age from 2006 to 2016. The initial data for this survey have been derived from ambulance/dispensary cards, hospitalization journals, and clinical data from the Registry of Blood Diseases at the R.Yeolyan Hematology Center, Yerevan, Armenia. The data has been supplemented by the data from the Registry of Oncological Diseases of the V. Fanarjyan NCO, as well as from death certificates. The demographic data has been obtained from the National Statistics Board of Republic of Armenia. The obtained data has been statistically analyzed using EPI INFO-2002 program.
Results: A total of 277 cases of childhood acute leukemia were identified, 174 (62.8%) of whom were male. The overall incidence of leukemia was 3.4 per 100 000 children-years. The higher incidence rates were noted in 2007, 2012, 2010 (accordingly 4.0, 4.0 и 3.9), and the lower rates in 2011, 2014, 2009 (accordingly 2.4, 2.4 и 2.9). There are three registrated regions in Armenia-Lori, Vayots Dzor and Tavush with higher incidence rate (respectively 0.020, 0.012 and 0.010 per 100 000 children-year). Currently 83.8% of studied patients are alive. The 5-year survival rate was 72%, 100%, and 100% among children diagnosed at 3–7, 7–13, and 13–18 years of age, respectively. The results indicated that the children diagnosed between ages of 3 and above had the lowest risk of mortality and higher survival rates.
Summary/Conclusions: This is the first general population study to describe the incidence of and mortality from childhood acute leukaemias in Armenia during 2006-2016. It forms the basis for quality assessment of acute leukaemia treatment in Armenia and offers a unique opportunity for population-based research. Age at diagnosis remained to be a crucial determinant of the survival variability of pediatric ALL patients, after adjusting for sex, race, therapy, primary tumor sites, immunophenotype, and year of diagnosis. Further research is warranted to disentangle the effects of age-dependent biological and environmental processes on this association.

PB1644

LONG-TERM SURVIVAL OUTCOMES OF ADULT PHILADELPHIA CHROMOSOME-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED WITH IMATINIB OR DASATINIB

G. Vahdani[1,*], A.-R. Jeong[1], Z. Ghaznavi[2], W. Hsiao[2], V. Tulpule[1], M. Akhtari[3]
[1]Department of Internal Medicine, LAC+USC Medical Center, [2]Keck School of Medicine, University of Southern California, [3]Jane Anne Nohl Division of Hematology and Center for the Study of Blood Diseases, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA, United States

Background: Acute lymphoblastic leukemia (ALL) with positive Philadelphia chromosome (Ph+) is a unique subset of ALL with poor prognosis. Recent studies have demonstrated improved survival outcomes in adult patients with Ph+ ALL with the use of tyrosine kinase inhibitors (TKIs) along with chemotherapy. However, there are very few studies that describe the comparative effectiveness of various TKIs in this patient population.
Aims: To characterize long-term survival outcomes including leukemia-free survival (LFS) and overall survival (OS) for Ph+ adult ALL patients treated with imatinib *versus* dasatinib.
Methods: Retrospective chart review was conducted at our institution. Patients >= 18 years old and diagnosed with Ph+ ALL between 2002 and 2015 were included. Analysis was done by intent to treat for patients initiated with imatinib or dasatinib at the time of Ph+ diagnosis. The primary endpoints were 2-year LFS and OS and secondary endpoints were complete molecular response (CMR; BCR-ABL1/ABL1 ratio <0.01% by PCR) and major molecular response (MMR; BCR-ABL1/ABL1 ratio <0.1% by PCR).
Results: Among 46 patients with Ph+ ALL, 74% (n=34) were in imatinib group and 17% (n=8) in dasatinib group; 9% were treated with other or no TKI (1 ponatinib and 3 with no TKI). Thirty-eight percent (n=13) of patients in imatinib group and 13% (n=1) in dasatinib group switched to a different TKI due to adverse effects or failure to achieve remission. There was a trend towards increased 2-year LFS for patients on dasatinib (HR 0.40, 95% CI: 0.14-1.14, p=0.09) and no difference in 2-year mortality (HR 1.00 95%CI: 0.46-2.17, p=0.99). Molecular response data was available for 61% (n=28) of patients; 75% of imatinib group achieved CMR or MMR (65% CMR) compared to 76% of dasatinib group (63% CMR) (p=0.98) (Figure 1).

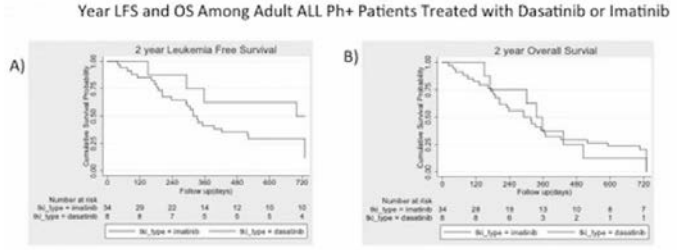

Figure 1.

Summary/Conclusions: In conclusion, dasatinib, compared to imatinib, in combination with chemotherapy, may prolong LFS in patients with Ph+ ALL and may be a suitable first-line agent. Large, randomized studies are needed to better define a detailed treatment protocol in this high-risk patient population.

PB1645

OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A MIXED COHORT OF PEDIATRIC AND ADULT PATIENTS WITH KMT2A-AFF1 ACUTE LYMPHOBLASTIC LEUKEMIA

T.L. Gindina[1,*], N. Mamaev[1], O. Paina[1], O. Pirogova[1], O. Slesarchuk[1], Y. Gudozhnikova[1], A. Alyanskiy[1], S. Bondarenko[1], L. Zubarovskaya[1], B. Afanasyev[1]
[1]R.M. Gorbacheva Memorial Research Institute of Children Oncology, Hematology and Transplantation, Department of Hematology, Transfusiology and Transplantation, 1st Pavlov State Medical University of Saint Petersburg, Saint-Petersburg, Russian Federation

Background: Acute lymphoblastic leukemia with poor-risk translocation t(4;11)(q21;q23)/*KMT2A-AFF1* occurs in all age groups with a clear dominance in children, especially up to 1 year. To date, allogeneic hematopoietic stem cell transplantation (allo-HSCT) is considered to be potentially curative treatment in high-risk acute leukemia patients, including the abovementioned.
Aims: To evaluate the prognostic impact of the different clinical and cytogenetic characteristics on the results of allogeneic hematopoietic stem cell transplantation in *KMT2A-AFF1* acute lymphoblastic leukemia patients.
Methods: Retrospective analysis of treatment results was performed for a mixed cohort of the patients with *KMT2A-AFF1* ALL who received allo-HSCT, including haploidentical one at our University over 2008 to 2015. Twenty-one patients (12 females and 9 males aged from 3 months to 48 years; median 18.9 years) were examined.

Results: Eight of 21 (38%) patients exhibited an isolated t(4;11) translocation. Additional chromosome abnormalities (ACA) were revealed in 11 (52%) patients, including 8 (42%) subjects with 3 and more chromosome aberrations. In univariate analysis, significance was shown for clinical stage at HSCT (1st remission *vs* other stages, 75% *vs* 0% p=<0,001 for OS; 58% *vs* 0%, p=<0,001 for EFS), complex chromosomal aberrations (<3 abnormalities *vs* ≥3 abnormalities, 58% *vs* 13%, p=0.04 for OS; 46% *vs* 0%, p=0.04 for EFS). According to multivariate analysis, the clinical stage at HSCT (HR 26.8, 95% CI 3.28-218.80; p=0.002 for OS; HR 11.18, 95% CI 2.92-42.80 p=0,0004 for EFS) was only independent prognostic factor for clinical outcomes.
Summary/Conclusions: The study has shown the stage of disease at the moment of allo-HSCT to be independent prognostic factor in a mixed cohort of *KMT2A-AFF1* ALL patients treated with HSCT. The good results of allo-HSCT can be obtained using a haploidentical transplantation from parents that removes the problem of searching the HLA-matched donors in the Registers and, therefore, greatly simplifies the treatment.

PB1646

DERMATOLOGIC COMPLICATIONS ASSOCIATED WITH TYROSINE KINASE INHIBITORS FOR THE TREATMENT OF ACUTE LEUKEMIA

K. Zarubina[1,*], O. Gavrilina[1], E. Parovichnikova[1], V. Troitskaya[1], A. Sokolov[1], E. Chelysheva[1], A. Turkina[1], E. Usikova[1], A. Abramova[1], G. Baskhaeva[1], I. Lukyanova[1], V. Savchenko[1]
[1]Department of chemotherapy of hemoblastosis and depression of hemopoiesis, National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Despite of targeted effects of tyrosine kinase inhibitors (TKIs), they are not absolutely selective in relation to their target. Hair pigmentation is regulated by factors including the interaction of the ligand stem cell factor (SCF) with its class III receptor tyrosine kinase, c-kit. Hair depigmentation observes during therapy TKI with action directed against class III receptor tyrosine kinase (PDGFRα, PDGFRβ, C-KIT, CSF1R, FLT3). But other TKI such as BCR/Abl TKI can also inhibit class III receptor tyrosine kinase by non-targeted actions. Skin reactions are the most common observed during the epidermal growth factor receptor-tyrosine kinase inhibitor treatment.
Aims: To describe the spectrum of skin and hair reactions in patients with acute leukemias (Ph+/Ph- acute lymphoblastic leukemia and acute myeloid leukemia) during the treatment by second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor (sorafenib).
Methods: From 2016 to March 2017 6 patients (pts), age 24-53 (median 29,5), 1 male, 5 female, received second or third line therapy with target tyrosine kinase inhibitors in National Research center for Hematology. One pt (pt 1) with AML had been receiving chemotherapy (decitabine, cytarabine, idarubicin) with continuous treatment of sorafenib. Three pts with Ph+ ALL received TKIs. Two of them with T315I mutation (pts 2, 3) received ponatinib and one pt (pt 4), without molecular remission on dasatinib and nilotinib therapy, received second-generation TKI (bosutinib). One pt with B-ALL was treated by sorafenib due to refractory disease on the first-line therapy (pt 5). And one patient (pt 6) with T-cell ALL received sorafenib with nelarabine containing chemotherapy due to early relapse after allogeneic stem cell transplantation.

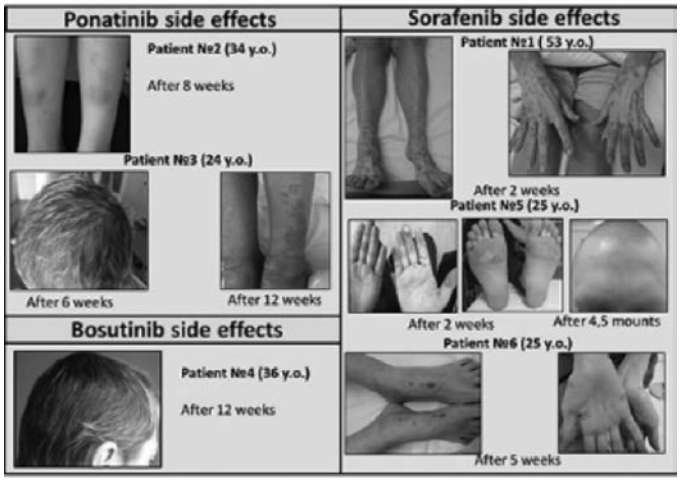

Figure 1.

Results: All of the 6 patients who had taken second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor sorafenib developed dermatologic reactions (skin rash or grey hair). Generalized maculo-papular skin rash grade II evolved after two weeks of sorafenib treatment in pt1. Both patients on ponatinib therapy developed localized maculo-papular skin rash grade I in pt 2 after 8 weeks of therapy. In pt 3 after 6 weeks of ponatinib treatment gray hair observed. Skin rash with pigmentation grade I evolved in pt 3 after 12 weeks of therapy. Pt 4 had gray hair after 12 weeks second-generation TKI (bosutinib) treatment. Palmar-plantar erythrodysesthesia syndrome grade II and hair and total skin depigmentation were evolved after 2 weeks and after 4,5 months respectively observed during the sorafenib treatment in pt 5 (with psoriasis anamnesis). Pt 6 developed localized maculo-papular skin rash grade I after 5 weeks of sorafenib treatment. Despite of all patients developed dermatological side effects, temporarily discontinuation of TKI therapy was required in only three (50%) cases. In the other cases the treatment was continued. The therapy was restarted in all pts with temporarily discontinuation after skin lesions disappearing (Figure 1).
Summary/Conclusions: Dermatological adverse events in acute leukemia pts who have taken second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor sorafenib they were not serious. Temporarily dose reduction or interrupting of TKI therapy led to complete regression of skin lesions. Restarting TKI at full dose did not lead to dermatological adverse reactions reappearing. Moreover, the temporary cancellation did not reduce its effectiveness.

PB1647

CYTOKINE RELEASE SYNDROME AFTER THE FIRST INTRATHECAL CHEMOTHERAPY IN A PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA WITH AN EARLY MENINGEAL RELAPSE

F. Petruzziello[1,*], M. Palma[1], A. Varone[2], M. Colonna[1], D. Cicala[3], N. Marra[1], G. Giagnuolo[1], G. Maisto[1], G. Menna [1], R. Parasole[1]
[1]Pediatric Hemato-Oncology, [2]Neurosciences, [3]Paediatric Neuroradiology Unit, Santobono-Pausilipon Hospital, Naples, Italy

Background: Central nervous system (CNS) is a frequent site of recurrence in childhood acute lymphoblastic leukemia (ALL), and Triple Intrathecal Therapy (TIT) with Methotrexate (MTX), Cytarabine (ARA-C) and hydrocortisone, at doses for age, is the mainstay of the treatment of CNS relapse. Severe neurotoxicity is well known TIT complication, usually related to repeated infusions and neurotoxic concomitant systemic drugs.
Aims: We describe a case of a massive acute leukoencephalopathy after only one TIT, in a 5 year-old child with an early isolated CNS relapse of ALL (26 months after the first diagnosis), rapidly proceeding to comatose status.
Methods: At admission for disease restaging at the end of first-line trial, the child showed physical and neurological examination completely negative, such as haematological, bioumoral and ultrasound findings. The cerebrospinal fluid (CSF) appeared turbid and liquoral pressure increased. CSF count showed 8100 cells/µl; morphology and flow citometry confirmed an early isolated CNS relapse. Due to the abnormal pleocytosis, TIT administration associated with oral dexamethasone was suddenly performed without any other concomitant chemotherapy. To prevent acute toxicities from tumor lysis syndrome, the patient received hydratation, allopurinol, acetazolamide and prophylaxis of seizures with levetiracetam. After few hours from TIT, the child developed severe headache followed by skin urticarial rash, high blood pressure and hallucinations, rapidly evolving in flaccid paralysis of lower extremities. A brain resonance (MRI) showed diffuse areas of hyperintensity of white matter, particularly cortical and subcortical areas, cerebellar region, optic chiasm and brainstem in T2-Flair sequences; spinal cord shower massive edema, especially in lombar region. The MRI pattern was interpreted as diffuse grade IV leukoencephalopathy of probable toxic nature. The child, 30 h after TIT, was transferred to intensive care unit for progressive ascending paralysis and respiratory distress that required intubation. During the following days, other three diagnostic lumbar puncture were performed that showed significant reduction of blasts cells (20, 10 and 0 cells /µL, respectively).
Results: Patient persisted in deep coma for 5 days, until he restart a spontaneous breathing. After waking up, the child showed rapid neurological ameliorations, such as reappearance of reflexes, spontaneous movements of eyes, hand and feet fingers. The subsequent MRI highlighted improvement of hyperintensity at midbrain, brainstem and bridge brain areas and spinal cord with persistence of altered signals in subcortical white matter. The visual evoked potentials were normal and the motor and sensory conduction velocity appeared slowed without axonal damage; EEG showed slow waves spread. At the moment, after three week from severe neurological complication, the child is fully awake, moving all four limbs, but requires motor and phoniatric rehabilitation. Systemic chemotherapy with high-dose MTX and IT ARA-C is restarted without any additional neurotoxicity. Dosage of CSF levels of interleukin 6 and its soluble receptor is ongoing.
Summary/Conclusions: Although leukoencephalopathy following IT MTX or ARA-C administration are described, the severity and rapidity of event's onset, associated with CSF remission after a single TIT administration, suggests us that neurotoxicity could be related to massive blast cytolysis with subsequent cytokine release syndrome causing an inflammatory leukoencephalopathy. This syndrome is a frequent complication of blinatumomab or chimeric antigen receptor T-cells administrations. The CSF IL-6 dosing could clarify the pathogenesis of the event.

PB1648

SEVERE HYPOFIBRINOGENEMIA ASSOCIATED WITH IMATINIB AND PREDNISONE THERAPY IN PHILADELPHIA CHROMOSOME–POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

M. Sciumè[1,*], N. S. Fracchiolla[1], G. Reda[1], R. Cassin[1], V. Mattiello[1], A. Cortelezzi[1]
[1]Oncohematology Division, IRCCS Ca' Granda - Maggiore Policlinico Hospital Foundation and University of Milan, Milan, Italy

Background: Hypofibrinogenemia associated to acute lymphoblastic leukemia (ALL) is rare and usually due to L-asparaginase. Consumption coagulopathy or therapy-related hepatotoxicity are other possible explanations. Severe hypofibrinogenemia, not linked to the causes listed, was rarely reported and a role of steroid therapy on fibrinogen metabolism was suggested.
Aims: Our aim was to identify the incidence of severe hypofibrinogenemia during induction phase in a cohort of consecutive ALL patients and to assess its impact on clinical decision-making.
Methods: In order to avoid confounding factor due to L-asparaginase, we revised our cohort of Philadelphia chromosome–positive (Ph^+) ALL that we treated according to pediatric-type therapy program (imatinib, intensive chemotherapy without L-asparaginase) for patients aged 18-65 years and through LAL0201-B protocol (imatinib, prednisone) for patients ≥65 years. We retrospectively analyzed coagulation tests on admission and during induction therapy of all Ph^+ALL patients diagnosed at our Institution from 2004.
Results: Twenty-one Ph^+ALL were identified; 17 patients were younger than 65 years, while the remaining 4 patients had a median age of 74 years (66-76). No alteration of plasma fibrinogen during induction was observed in younger patients. Severe hypofibrinogenemia (≤100 mg/dl) was detected in 3 out of 4 Ph^+ALL over 65 years. In these patients induction consisted of prednisone 40 mg/m^2/dfrom day 1 to 45 and imatinib at the fixed dose of 800 mg/d. On admission hemoglobin levels were ≥10 g/dl in all patients, leucocytes counts were 2x10^9/L (blasts 15%), 8x10^9/L (blasts 30%) and 18x10^9/L (blasts 61%), while platelet count was reduced in 2 cases (61x10^9/L and 65x10^9/L). Coagulation tests were normal (fibrinogen median level 380 mg/dl). Severe hypofibrinogenemia developed between 6 and 15 days after beginning treatment and lasted between 4 and 48 days. Fibrinogen nadir ranged from 47 to 100 mg/dL (median 61 mg/dL); reduced plasma fibrinogen levels at functional tests were also confirmed to immunological assays. During fibrinogen nadir, D-dimer was positive in all patients, but stable compared to the outset. Antithrombin, coagulation factors, activated partial thromboplastin and prothrombin time, common liver function tests remained in a normal range; platelet counts showed a trend to normalization. Early clearance of peripheral blood blasts was observed and when hypofibrinogenemia appeared no blast cells were detectable. At the end of induction bone-marrow evaluation demonstrated the absence of BCR-ABL transcript by qualitative RT-PCR. There were no bleeding events and only one patient received a prophylactic transfusion of fresh-frozen plasma (10 ml/kg) for fibrinogen <50 mg/dl on two occasions. Normal fibrinogen levels (≥165 mg/dl) were recovered at the end of steroid therapy.
Summary/Conclusions: We observed severe hypofibrinogenemia in Ph^+ALL patients older than 65 years treated with imatinib and high-doses steroid, while normal fibrinogen levels were detected in younger Ph^+ALL during intensive chemotherapy plus imatinib. In our experience, hypofibrinogenemia was not associated to major bleeding events, although its clinical significance should be investigated in larger series. Fibrinogen may recognize multiple metabolic pathways, also unrelated to *in vivo* coagulation and fibrinolysis; the correspondence between steroid treatment and hypofibrinogenemia seems to suggest that glucocorticoids may alter some steps in fibrinogen kinetics and could be considered as a cause of acquired hypofibrinogenemia.

PB1649

LATE EFFECTS OF CHEMORADIOTHERAPY ON THE ENDOCRINE SYSTEM IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

G. Aydogan[1,*], S. Eltan[1], F. Akici[1], Z. Salcioglu[1], A. Akcay[1], T. Akcay[1], H. Sen[1], N. Ozdemir[1], C. Bayram[1], A. Aycicek[1]
[1]Pediatric Hematology, KANUNI SULTAN SULEYMAN EDUCATION AND RESEARCH HOSPITAL, Istanbul, Turkey

Background: Over the past four decades treatment of childhood acute lymphoblastic leukemia has been modified with the aim of achieving high survival rate while reducing the risk of the life threatening late-effects and promoting risk-based follow-up care of survivors.
Aims: The aim of our study is evaluation of late effects of chemotherapy and cranial radiotherapy on the endocrine system in children with acute lymphoblastic leukemia.
Methods: Fourty-eight patients, who were diagnosed and treated for ALL between 1997-2007 in Istanbul Kanuni Sultan Suleyman Education and Research Hospital Pediatric Hematology-Oncology Clinic and have disease-freee for at least 5 years after cessation of treatment, were evaluated prospectively. The study form included each patients age, gender, weight, height, target height, parental height, treatment protocol, stage of puberty, bone age, TSH, free T4, LH, FSH, estradiol or testosterone, IGF-1 and IGFBP-3 levels. Annual rate of growth was evaluated for each patient. The patients with inadequate growth rate and delayed bone age were subjected to growth hormon stimulation test with clonidine.
Results: Mean age of the patients was 14.41±2.85 (10.5-22.4) years. Thirty-one of patients had prophylactic cranial radiotherapy; five of them 18 Gy and twenty-six had 12 Gy CRT. Fifteen of the 48 patients were diagnosed with at least one endocrinological disorder. Six patients had lower height (<-2 SD), three patients had a body mass index >30kg/m². Bone age delayed in two patients. Four patients had IGF-1 value below <-2SD and two patients had inadequate levels of growth hormone. Tanner stage of the patients were appropiate for their ages except for one patient with hypergonadotropic hipogonadism and one patient with pubertas precox. Subclinical hypotiroidism was detected in two patients.
Summary/Conclusions: Significant late effects may develop over time in children treated for ALL. For this reason long-term follow-up of these children is necessary. Because of the awareness of the late effects can the treatment modifed to reducing of the late effects.

Acute myeloid leukemia - Biology

MUTATIONAL ANALYSIS OF 231 DE NOVO AML PATIENTS BELOW 60 YEARS WITH CURATIVE THERAPY

A. Folta[1,*], I. Jeziskova[1], D. Dvorakova[1,2], N. Tom[2], M. Culen[1,2], Z. Kosarova[2], A. Durinikova[2], P. Cetkovsky[3,4], P. Jindra[4,5], T. Szotkowski[4,6], P. Zak[4,7], J. Mayer[1,2,4], Z. Racil[1,2,4]
[1]University Hospital Brno, [2]Masaryk University, Brno, [3]Institiute of Hematology and Blood Transfusion, Prague, [4]On behalf of CELL, Brno, [5]University Hospital Pilsen, Pilsen, [6]University Hospital Olomouc, Olomouc, [7]University Hospital Hradec Kralove, Hradec Kralove, Czech Republic

Background: Acute myeloid leukemia (AML) is an aggressive cancer disease of the myeloid lineage of blood cells, characterized by rapid growth of undifferentiated myeloid precursors. Analysis of the spectrum of somatic mutations in leukemic cells may help to improve the identification of individual prognostic subgroups of patients as well as to observe clonal evolution in the course of AML treatment.
Aims: The aim of the project is to identify somatic alterations in genes related to AML using next generation sequencing (NGS) in large cohort of AML patients from Czech Republic and to determine their frequency and mutual coexistence.
Methods: The analyzed group consists of 231 *de novo* consecutively diagnosed AML patients with curative therapy below 60 years from five hematological centers. The NGS libraries are prepared from peripheral blood samples from diagnosis using ClearSeq AML panel (Agilent Technologies) and sequenced on MiSeq and NextSeq machines (Illumina). As positive are determined mutations with variant allele frequency (VAF) at least 2%.
Results: At least one somatic mutation (median 2; range 0-6) was identified in 204 (88.3%) patients with *de novo* AML. In total, 526 recurrent mutations in 19 genes were identified. The most frequently mutated genes were: *FLT3* 91/231 (39.4%; from this *FLT3*-ITD 69/231 [29.9%] and *FLT3*-TKD 22/231 [9.5%]), *NPM1* 90/231 (39.0%; mutation type A 71/90 [78.9%], type B 11/90 [11.1%], other types 10/90 [10.0%]), *DNMT3A* 68/231 (29.4%; mutations in codon R882 49/68 [72.1%]), *NRAS* 51/231 (22.0%; the most frequent mutation G12D 17/51 [22.0%]; 11/51 patients [21.6%] contain more than one mutation in *NRAS* gene), *IDH2* 35/231 (15.2%) and *CEBPA* 35/231 (15.2%). The analysis also identified mutations in rarely mutated genes *U2AF1*, *SF3B1*, *EZH2* and *SETBP1* in 4/231 (1.7%), 4/231 (1.7%), 1/231 (0.4%) and 1/231 (0.4%) samples, respectively (Figure 1).

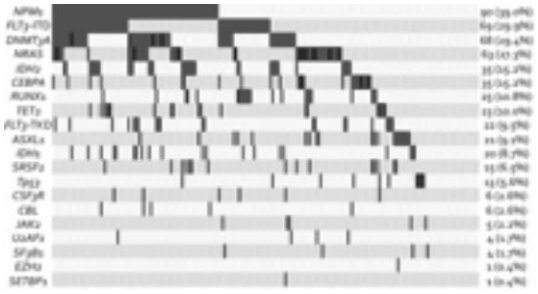

Figure 1. Distribution of gene mutations with VAF ≥2% in AML cohort. Each column represents one patient (n=231). Each row represents one gene described on left, on the right is shown the number of patients with mutation in the gene and its percentage from the total cohort. The color of the squares represents the status of the gene: red – single mutated, blue – double mutated, black – triple mutated, white/grey – no mutation.

Summary/Conclusions: The results of mutational analysis of large cohort of AML patients show high heterogeneity of detected mutations. Surprisingly we have detected high percentage of patients with mutations in gene *NRAS*. Together with sequencing results from the time of remission/relapse/resistance of the disease, the data will enable to get more complex view on the development of AML in time.
Supported by Ministry of Health of the Czech Republic, grant nr. 15-25809A, and by project MUNI/A/1106/2016.

INHIBITION OF LIN28B IMPAIRS LEUKEMIA CELL GROWTH AND METABOLISM IN ACUTE MYELOID LEUKEMIA

J. Zhou[1,*], J.-Y. Chooi [1], J.Y. Quah[1], S.H.-M. Toh[1], T.Z. Tan[1], P.S. Chong[1], W.-J. Chng[1]
[1]Cancer Science Institute of Singapore, National University of Singapore, , Singapoore, Singapore

Background: 1. Current conventional chemotherapy for acute myeloid leukemia (AML) can achieve remission in over 70% of patients, but a majority of them will relapse within 5 years despite continued treatment. 2. The relapse is postulated to be due to leukemia stem cells (LSCs), which is different from normal hematopoietic stem cells (HSCs). LIN28B is microRNA regulator and stem cell reprogramming factor. 3. Overexpression of LIN28B has been associated with advance human malignancies and cancer stem cells (CSCs), including AML. However, the molecular mechanism by which LIN28B contributes to the development of AML remains largely elusive.
Aims: 1. To study the function role of LIN28B in cell proliferation, cell cycle and colony formation ability of AML cells. 2. To systematically dissect transcriptional signalling mediated by LIN28B on whole genome level. 3. To determine the key targets of LIN28B in AML. 4. To explore the function of LIN28B in AML *in vivo*.
Methods: 1. We modulated LIN28B expression in AML and non-leukemic cells and investigated functional consequences in cell proliferation, cell cycle and colony forming assays. 2. We performed a microarray-based analysis for LIN28B-silencing cells and interrogated gene expression data with different bioinformatic tools. 3. AML mouse xenograft model was used to examine the *in vivo* function of LIN28B.
Results: We first showed that increased LIN28B expression was associated with worse survival in AML patients. We demonstrated that targeting LIN28B in AML cells resulted in cell cycle arrest, inhibition of cell proliferation and colony formation, which was induced by de-repression of let-7a miRNA. On the other hand, overexpression of LIN28B promoted cell proliferation. Mechanistic studies revealed that inhibition of LIN28B induces metabolic changes in AML cells. IGF2BP1 was confirmed to be a novel downstream target of LIN28B via let-7 miRNA in AML. Notably, silencing LIN28B led to slow tumor growth *in vivo*.
Summary/Conclusions: In conclusion, these results uncover a novel mechanism of an important regulatory signaling, LIN28B/let-7/IGF2BP1, in leukemogenesis and provide a rationale to target this pathway as effective therapeutic strategy.

EVALUATION OF MINIMAL RESIDUAL DISEASE IN NPM1-MUTATED AML PATIENTS

C. Martínez-Laperche[1,2,*], V. Pradillo[1], G. Rodríguez-Macías[1], M. Chicano[1,2], D. Carbonell[1,2], J. Suárez-Gónzalez[2], J. L. Díez-Martín[1,2], I. Buño[1,2]
[1]Hematology, H.G.U Gregorio Marañon, [2]Instituto de Investigación Sanitaria Gregorio Marañon, Madrid, Spain

Background: Minimal residual disease (MRD) tests provide early identification of hematologic relapse and timely management of AML patients. About 60% of adult normal karyotype AML has a mutation in exon 12 of *NPM1* gene. This mutation is specific for malignant clone and potentially is a good marker of MRD.
Aims: The aim of the study was to analyze the usefulness of *NPM1* as a marker for MRD quantification in AML during follow-up.
Methods: Retrospective study included 34 patients with mutated-NPM1 and treated with intensive chemotherapy (2009-2015). Bone marrow (188) and peripheral blood (277) samples were analyzed from complete remission (MRD *NPM1* negative). *NPM1* detection was performed by quantitative RT-PCR (*Gorello et al, Leukemia 2006*). Patients were considered positive when presented >1 *NPM1* sample positive or/and one sample NPM1 >0.02%. Cox regression was used for univariate analysis.

Variable	HR (CI 95%)	p
Gender (male/female)	0.9 (0.9-2.9)	0.8
Age (> 55.3)	**5.8 (1.3-27)**	**0.024***
Leukocyte count (>30x103/ul)	**6.7 (1.4-31.2)**	**0.015***
LDH (>499 U/ml)	**7.4 (1.5-35.6)**	**0.013***
FLT3-ITD	1.7 (0.5-5.7)	0.4

DNMT3A	0.7 (0.2-2.5)	0.6
Post-induction (PR)	1.2 (0.9-1.4)	0.1
Post-induction (MFC > 0.1)	0.6 (0.1-3.1)	0.6
Post-consolidation (PR)	-	
Post-consolidation (MFC > 0.1)	1.3 (0.3-6.1)	0.7
MRD NPM1 positive	**8.9 (1.4-32)***	**0.029***

Univariate analysis

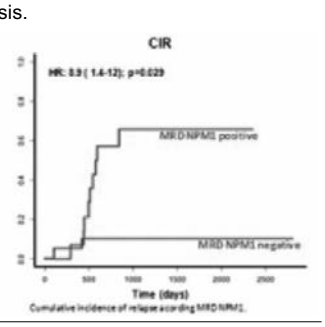

Figure 1.

Results: Patients were segregated in 2 groups: Relapse patients (Group 1: 32.2%, 11/ 34) and no relapse patients (Group 2: 67.6%, 23/34). Group 1 presented MRD *NPM1* positive in 9/11 (82%) of patients, the time from *NPM1* to relapse was 4.6 months (1.6-24), *NPM1* mean was 1.7 (0.03-9). Group 2 presented MRD *NPM1* negative (<0.02% y/ or 1 determination) in 21/23 (91%) patients. Univariate analysis was performed and our results show that age, leukocyte, LDH and MRD *NPM1* are prognostic factors for cumulative incidence of relapse (Figure 1).

Summary/Conclusions: *NPM1* is a useful marker for MRD quantification in AML patients undergoing intensive therapy. *NPM1* positive during follow-up is associated with a higher probability of relapse.

PB1654

AT101 ELIMINATES AML STEM CELLS VIA ACTIVATION OF INTRINSI C APOPTOTIC PATHWAY AND PARTICIPATION IN DNA DAMAGE RESPONSE

X. Bing[1,*], Z. Leisi[2], Z. yong[1], C. kai[2], S. pengcheng[3], L. yin[2], D. manman[1], J. zhiwu[4], W. xiangmeng[2], L. peng[4]
[1]The First Affiliated Hospital of Xiamen University, Xiamen, [2]Nanfang Hospital, Southern Medical University, Guangzhou, [3]Nanfang Hospital, Southern Medical University, Xiamen, [4]Southern China Institute for Stem Cell Biology and Regenerative Medicine, Guangzhou, China

Background: Leukemia stem cells (LSCs) are considered as the main reason for treatment failure and relapse in acute myeloid leukemia. Overexpression of Bcl-2 anti-apoptotic proteins is associated with the survival and self-renewal of LSCs
Aims: To observe the effect for AT101 to eliminate AML stem cells and its underlying mechanism.
Methods: Use $CD34^+CD38^-CD123^+KG1\alpha$ and primary AML $CD34^+$ cells as research object.
Results: In this study, we demonstrated that AT101, a BH3 mimetic pan-Bcl-2 inhibitor, was significantly and effectively cytotoxic towards $CD34^+CD38^-CD123^+KG1\alpha$ and primary AML $CD34^+$ cells, with slight effect on $CD34^+$ normal hematopoietic cells. And the mechanism was closely associated with activation of intrinsic apoptotic pathway, such as loss of mitochondrial membrane potential and caspase activation, along with disturbance of DNA damage response. Further analysis on AML patients' clinical characteristics revealed that the *ex vivo* efficacy of AT101 in primary samples was significantly correlated to hyperleukocytosis or *FLT3-ITD* mutation. Besides, AT101 exhibited exciting effect on $CD34^+$ blasts from patients who are old or cannot achieve CR after induction therapy.
Summary/Conclusions: In conclusion, Together, these findings provides potentiality for the use of AT101 to treat relapse and refractory AML as alternative salvage regime in the future, including those clinically characterized by one or more adverse prognostic abnormalities.

PB1655

COOPERATIVE EFFECT OF CHIDAMIDE AND CHEMOTHERAPEUTIC DRUGS INDUCE APOPTOSIS BY DNA DAMAGE ACCUMULATION AND REPAIR DEFECTS IN ACUTE MYELOID LEUKEMIA STEM AND PROGENITOR CELLS

X. Bing[1,*], L. Yin[2], D. Manman[1], C. Kai[3], S. Pengcheng[4], Z. Yong[1]
[1]The First Affiliated Hospital of Xiamen University, Xiamen, [2]Huizhou Municipal Central Hospital, huizhou, [3]Nanfang Hospital, Southern Medical University, Guangzhou, [4]Nanfang Hospital, Southern Medical University, Xiamen, China

Background: Lots of conventional chemotherapeutic drugs are confirmed to take participate in DNA damage generation and initiation of DNA damage response, ultimately leading to apoptosis. However, they fail to completely eliminate leukemia stem cells (LSCs) on account of higher DNA repair capacity of cancer stem cells than bulk cancer cells, which become the root of resistance and recurrence. Thus, new strategy to eliminate LSCs in AML is urgently needed.
Aims: To observe the effect of low dose chidamide in combination with chemotherapeutic agents on eliminating AML stem cells.
Methods: we uesed a novel benzamide-type HDAC inhibitors, chidamide,in combination with DNA-damaging agents (daunorubicin, idarubicin and cytarabine) to treat CD34+CD38- KG1α cells and primary refractory or relapsed AML CD34+ cells.
Results: Here, we report that low dose chidamide, a novel benzamide-type HDAC inhibitors, which selectively targeted HDAC 1, 2, 3, 10, could enhances cytotoxicity of DNA-damaging agents (daunorubicin, idarubicin and cytarabine) in CD34+CD38- KG1α cells and primary refractory or relapsed AML CD34+ cells, reflected by inhibition of cell proliferation and induction of apoptosis *in vitro*. Mechanistically, these events were associated with DNA damage accumulation and repair defects. Co-treatment with chidamide and DNA-damaging agents IDA gave rise to production of γH2A.X, inhibited ATM, BRCA1, checkpoint kinase 1 (Chk1) and 2 (Chk2) phosphorylation. Finally, the combination initiated caspase-3 and PARP cleavage and ultimately induced $CD34^+CD38^-$ KG1α cells apoptosis. Further analysis on AML patients' clinical characteristics revealed that the *ex vivo* efficacy of chidamide in combination with IDA in primary CD34+ samples was significantly correlated to peripheral blood WBC counts at diagnosis, while status, LDH level, karyotype had no effect, indicating that the combination regimen of chidamide and IDA could rapidly diminish tumor burden in a patient with R/R AML.
Summary/Conclusions: these findings provide preclinical evidence for low dose chidamide in combination with chemotherapeutic agents to treat recurrent/resistant AML as an alternative salvage regimen, especially those possessed stem and progenitor cells.

NEW CANDIDATE GENES USEFUL TO PREDICT THE RISK OF RELAPSE IN ACUTE PROMYELOCYTIC LEUKEMIA

J. Nanni[1,*], M.C. Fontana[1], G. Marconi[1], C. Papayannidis[1], S. Lo Monaco[1], G. Simonetti[1], A. Padella[1], E. Ottaviani[1], S. Paolini[1], M.C. Abbenante[1], L. Bertamini[1], G. Martinelli[1]
[1]University of Bologna, Bologna, Italy

Background: Nowadays, Acute Promyelocytic Leukemia (APL) is a disease entity with a very high rate of cure and an estimated 2-year overall survival of 97%. Early death, rather than resistant disease so common in all other subtypes of AML, has emerged as the major cause of treatment failure, and relapse is a very rare occurrence.
Aims: APL relapse is a very rare entity, and it is announced to become rarer with the advances in first line therapy. Molecular characteristics are hard to analyze without an effort to collect and bank samples together from multiple institutions. Since relapses, especially relapses out of follow-up period, represent a sudden life-treating condition for patients, to predict patients at higher risk of relapse we selected two candidate genes that could be involved in pathways favoring relapse.
Methods: We collected data of all the APL referred to our institution from 2014. Within 23 patients, we encountered 20 new diagnosis and 2 relapse of APL. We analyzed blasts in samples obtained from Bone Marrow with Single Nucleotide Polymorphisms Array Cytoscan HD.
Results: We compared copy number alterations in both relapsed patients with alterations detected in the pool of 20 newly diagnosed APL and we found specific signatures of CN*Vs* for each patient. There were several copy number alterations related to each patient: the first patient presented gain of *ROBO2*, *GRIP1*, *CTNNB1*, *SOX6*, *PBX1*, *GRIK2*, *CDKAL1* and loss *FAF1*, *CREBBP*, *SBF1*; the second patient presented gain of *ROBO1*, *MAPK10*, *CADPS2*, *APBA1* and loss of *GRIP1* and *MYB*. Subsequently we focused our attention on *ROBO* and *GRIP1*genes because they were alterated in both relapsed patients: ROBO proteins are associated to K channels while GRIP1 is involved in various critical functions, for example in androgen receptor binding, beta-catenin binding, glucocorticoid receptor binding, and it is also a regulator of glutamate metabolism, a well-known pathway in Leukemic Stem Cells.
Summary/Conclusions: By the analysis of ROBO 1-2 and GRIP1 at the diagnosis of APL we could establish a different and strict follow-up program for patients with these alterations.

THE EXPRESSION OF SALL4 AND BMI-1 GENES IN MYELOID LEUKEMIA

M. El-Nagdy[1,*], H. Farawela[1], H. Zawam[2], H. Al-Wakeel[1], F. El-Refaey[3], H. Abdel-Rahman[1]
[1]Clinical & Chemical Pathology, [2]Medical Oncology, Cairo University, [3]Clinical & Chemical Pathology, National Cancer Institute, Cairo, Egypt

Background: Sal-like protein 4 (SALL4) and B-cell specific moloney murine leukemia virus integration site-1 (BMI-1) genes are stem cell genes that modulate stem cell pluripotency and may play a role in leukemogenesis. Leukemic stem cells (LSCs) have been implicated in being the origin of the leukemic blast, therapy resistance and relapse.
Aims: The current study aimed at characterizing the expression pattern of SALL4 and BMI-1 genes in acute myeloid leukemia (AML) and chronic myeloid leukemia (CML), in patients who have achieved complete remission (CR), and in CML disease progression.
Methods: Real-time polymerase chain reaction was used to assess the gene expression patterns in 106 myeloid leukemia patients; 54 de novo AML (43 at time of diagnosis, 11 in CR), and 52 CML (31 in chronic phase (CP), 11 in deep molecular response (MR^4) & 10 in accelerated/blastic phase (AP/BP), and in 21 non malignant bone marrow samples.
Results: SALL4 gene expression was increased in AML patients, AML-CR, & CML-CP (median= 5.180, 4.604 & 14.125 respectively). No significant difference was observed between de novo AML and AML in CR patients. CML-CP patients showed a significantly higher percentage of patients with a high SALL4 expression as compared to both CML- MR^4 and CML-AP/BP (p=0.033). BMI-1 gene expression was not found to be increased in any of the patient groups.
Summary/Conclusions: Our data describe altered SALL4 gene expression in different phases of myeloid leukemia. The role of BMI-1 gene needs further delineation to determine its significance.

AN INVESTIGATION INTO THE ROLE OF S100A8 AND S100A9 IN ACUTE MYELOID LEUKAEMIA

S. Chaudry[1,*], T. Chevassut[1], H. Stewart[1]
[1]Brighton and Sussex Medical School, Brighton, United Kingdom

Background: Acute myeloid leukemia (AML) is the a haematological malignancy characterised by the over proliferation and block in differentiation of clonal stem cells. In leukaemia potential biomarkers such as S100A8 could assesses the progression and remission of AML.
Aims: S100A8 and S100A9 (Ca2+ binding helix E-loop-helix-F hand), are inflammatory markers which are also suggested to promote chemoresistance by stimulation of autophagy. Microarray data from the Chevassut lab shows that both S100A8 and S100A9 transcripts are downregulated by the BET-bromodomain inhibitor JQ1 in AML cell lines. We aimed to investigate this response in AML patient bone marrow samples and cell lines.
Methods: We used AML cell line including OCI-AML2, OCI-AML3 and THP-1 in addition to AML patient bone marrow samples and healthy volunteer samples. We carried out RT-qPCR and immunocytochemistry and western blotting techniques to look at levels of S100A8 and S100A9 in samples.
Results: Here we show that levels of S100A8 and S100A9 mRNA levels are suppressed in response to JQ1 in the AML cells lines OCI-AML2, OCI-AML3 and THP-1. We find also that protein levels of S100A8 and S100A9 are downregulated in response to JQ1 in OCI-AML3. In bone marrow samples of 17 AML patients with different cytogenetic profiles, the relative expression of S100A8 and S100A9 was found to be variable amongst the samples but also in comparison to OCI-AML3 cell line. In further experiments using AML patient bone marrow samples, treatment with JQ1 showed suppression of S100A8 and S100A9 in some patient samples but enhanced expression in other bone marrows. In peripheral blood samples of healthy volunteers, we found that treatment with JQ1 showed notable suppression of both S100A8 and S100A9; with a greater suppression being observed in the monocyte fraction of the samples.
Summary/Conclusions: Our data suggests that JQ1 regulates the expression of S100A8 and S100A9 in AML. The variability of the response seen amongst AML patient samples and AML cell lines may be reflective of the genetic profiles driving the leukaemogenic process in these samples Further work may give more detailed insight into the mechanisms of action and potential use of S100A8 and S100A9 in AML prognostic markers.

PB1660

SUCCESSFUL COVERAGE OF DIFFICULT TO SEQUENCE GENES (CALR, CEBPA, AND FLT3) ASSOCIATED WITH MYELOID DISORDERS USING A HYBRIDISATION-BASED ENRICHMENT APPROACH PRIOR TO NEXT-GENERATION SEQUENCING

G. Speight[1,*], L. Georgieva[1], E. Uddin[1]
[1]R&D, Oxford Gene Technology, Begbroke, United Kingdom

Background: The application of short read NGS for research into myeloid disorders such as myeloproliferative neoplasms (MPNs) and acute myeloid leukaemia (AML) has been hampered by the inability to sequence certain genes. These genes can harbour key mutations so it is desirable to ensure suitable sequencing coverage is obtained. These genes amongst others include: *CALR* exon 9 insertions and deletions (up to 52 bp), *CEBPA* single nucleotide variants (SNVs) and *FLT3* Internal Tandem Duplications (ITDs) and SN*v*s Each of these regions contain certain challenging DNA sequences that can impact the quality of the data generated, *e.g.* large indels and low complexity regions (*CALR*), high GC content (75% on average for the whole gene with specific regions at 100%) and repetitive regions (*CEBPA*), and complex repetitive elements (*FLT3*).
Aims: To determine whether a hybridisation-based enrichment approach overcomes the difficulties associated with these genes, and permits the generation of high quality (sufficient de-duplicated depth) data to allow these targets to be accurately interrogated.
Methods: We utilised a hybridisation-based enrichment approach for library preparation in combination with a SureSeq myPanel™ NGS Custom AML panel. The library was then sequenced using a 2x150 bp read length protocol on an Illumina MiSeq®.
Results: Here we present the coverage and variants generated from numerous research samples for each of these difficult to sequence genes. The results clearly show that this approach can reliably detect and accurately size (including low allele frequency) insertions and deletions of up 52 bp in *CALR* (exon 9), SN*V*s and deletions in *CEBPA* with a de-duplicated depth in excess of 2000x as well as ITDs of between 24 and 201 bp in *FLT3*.
Summary/Conclusions: This approach is suitable for the analysis by NGS of these difficult genes and therefore removes the requirements for supplementary approaches to analyse these difficult genes, such as Sanger sequencing (*CEBPA*) and fragment analysis (*CALR* and *FLT3*).

PB1661

ASSOCIATION OF MIRNA EXPRESSION PROFILES WITH FUNCTIONAL AND MOLECULAR ACUTE MYELOID LEUKEMIA CATEGORIES

C. Sargas[1,*], M. Llop[2], M. C. Alonso[3], R. Ayala[4], M. E. Onecha[4], M. Ibañez[2], B. De Matteo[1], J. Cervera[2], E. Such[2], P. Montesinos[2], R. Rodríguez[2], D. Martinez[2], B. Boluda[2], M. Á. Sanz[2], E. Barragán[2]
[1]Instituto de Investigación Sanitaria La Fe (IIS La Fe), [2]Hospital Universitario y Politécnico La Fe, [3]Hospital Arnau de Vilanova, Valencia, [4]Hospital 12 de Octubre, Madrid, Spain

Background: Development of high-throughput technologies such as Next Generation Sequencing (NGS) allowed the identification of recurrent mutated genes in Acute Myeloid Leukemia (AML), and new molecular markers which help refine patients' classification in different risk groups.
Epigenetic alterations such as aberrantly expressed microRNAs (miRNAs) also play an important role on the pathogenesis of AML. miRNAs control processes such as cell development, differentiation, proliferation and apoptosis. Therefore, aberrant miRNA expression can affect signaling and metabolic pathways, directing cancer cell biological behavior.
Recently, several studies have classified AML according to different criteria. TCGA proposed in 2013 a new classification where genes are grouped according to their biological function. Moreover, Papaemmanuil *et al*. suggested in 2016 a new classification based on molecular markers with not overlapping categories.
Aims: Our aim is to explore the miRNA profile of NK-AML and to find expression profiles associated with the categories proposed by TCGA and Papaemmanuil *et al*. Associations of miRNA expression profiles with altered categories could help understand the molecular mechanisms that lead to leukemogenesis.
Methods: CD34+ cord blood progenitor cells from 5 healthy donors and 7 CD34+ NK-AML samples with >70% blasts were obtained. Total RNA from these samples were hybridized onto an Array miRNA 3.0 chip (*Affymetrix*) in order to identify deregulated miRNAs. The most deregulated miRNAs were validated by qRT-PCR (*miScript*) in an independent cohort of 73 patients. Mutational analysis was performed by Next Generation Sequencing using the AML Community Panel with the Ion Torrent System (*Life Technologies*). Mann-Whitney U test was used to determine which miRNAs were differentially expressed among categories.
Results: We found a profile of 6 miRNAs up-regulated and 61 miRNAs down-regulated in NK-AML *vs* CD34+ cells. Validation by qRT-PCR confirmed that miR-494 (p=0.028) and miR-4507 (p=0.035) were up-regulated and miR-27b (p=0.022), miR-99a (p=0.001), miR-146b (p=0.031), miR-151b (p=0.006) and miR-20b (p=0.001) were down-regulated in NK-AML. Interestingly, some of the deregulated miRNAs were significantly associated to a functional category according to the TCGA classification. Therefore miR-146b was down-regulated in AML with mutations in myeloid transcription factors (p=0.025). Low expression of this miRNA causes the activation of the kB factor signaling pathway, which increases transcription. miR-4668 was down-regulated in AML with mutations in activation pathways genes (p=0.004), several target predictors propose *RASGEF1A* and *BRAF* as targets of this miRNA. Thus, under-expression of this miRNA could cooperate with mutations leading to the activation of signaling pathways. Regarding to Papaemmanuil´s molecular classification, miR-494 was up-regulated in IDH2-R172 category (p=0.009). High levels of this miRNA are associated with lower expression of *TET*, specially *TET1*. Therefore, high levels of miR-494 could contribute to the hypermethylation signature of IDH mutations.
Summary/Conclusions: In conclusion, the mutational landscape of significant functional and molecular groups in AML is accompanied by miRNA deregulation, which could cooperate in the development of this hematologic malignancy.

PB1662

PROTEOMIC APPROACH TO IDENTIFY MOLECULAR TARGETS OF HALOFUGINONE IN ACUTE MYELOID LEUKEMIA

L. Cândido[1,*], C. Silva[2], D. Moreno[1], C. Thomé[3], A. Nagler[4], E. Rego[5]
[1]Hematology Division of the Department of Internal Medicine, School of Medicine University of São Paulo, [2]Laboratory of Experimental Animal Studies, Faculty of Medicine of Ribeirão Preto - University of São Paulo, [3]Hematology Division of the Department of Internal Medicine, University of São Paulo, Ribeirão Preto, Brazil, [4]Hematology Division and Cord Blood Bank, Chaim Sheba Medical Cente, Tel Aviv University, Tel Hashomer, Israel, [5]National Institute of Science and Technology on Cell-Based Therapy, School of Medicine of Ribeirão Preto - University of São Paulo, Ribeirão Preto, Brazil

Background: Halofuginone (HF) is a halogenated derivative of Febrifugine, which is a molecule isolated from the plant Dichroa febrifuga. It has been demonstrated that Halofuginone exhibits anti-fibrotic, anti-cancerogenic, anti-inflammatory and pro-apoptotic effects. Previously, we have reported that treatment with HF has anti-leukemic properties in-vitro and in-vivo in acute promyelocytic leukemia (APL), reducing tumor growth through the induction of apoptosis and by stimulating the synthesis of the TGF-β protein and activating its downstream targets. In addition, HF presented anti-angiogenic effects by modulating the level of pro and anti-angiogenic factors including VEGF. However, it is unknown whether HF has anti-leukemic activity against other subtypes of acute myeloid leukemia (AML) and HF targets were not determined yet.
Aims: Evaluate the anti-leukemic effect of HF on other AML subtypes than APL and investigate its targets using a proteomic approach.

Methods: AML cell lines Kasumi-1, THP-1, MV4-11, U937 and OCI-AML3 were treated in- vitro with HF at concentrations ranging from 25 to 1000 ng/ml. The% of apoptotic cells, the distribution of cells in different cell cycle phases, and the HF IC_{50} was determined for each cell line. We used the Proteome Profiler ™ Array – HumanPhospho-Kinase Array to verify the possible tyrosine kinases and signaling pathways that could be modulated by HF. To analyze the in-vivo effect of HF, we transplanted the cell lines Kasumi-1 and THP-1 into NOD.Cg-Prkdc^{scid} Il2rg^{tm1Wjl}/SzJ (NSG) mice, which were then treated by intraperitoneal injections of HF at a dosage of 150 mg/Kg daily for 14 days. The leukemic infiltration of the peripheral blood was quantified by flow cytometry every 2 weeks (using a anti-human CD45+).
Results: HF IC50 values ranged from 125.58 ng/ml in Kasumi-1 to 786.15 ng/ml in THP-1 cells. Kasumi-1 cells halted in the S phase of the cell cycle when treated with HF, displaying a significant decrease in proliferation, while no effect was observed for THP-1 cells. Corroborating our in-vitro observation indicating resistant of THP-1 cells towards HF, we did not detect significant differences in the overall survival (OS) of NSG mice transplanted with THP-1 cells treated with vehicle or HF (mean OS of 70,5 and 68 days, respectively; p= 0,24). In contrast, the mean OS for NSG mice transplanted with Kasumi-1 cells treated with HF was significantly prolonged compared to the control group (144 *versus* 94.5 days; p= 0.007). The proteomic analysis identified significant decrease upon treatment with HF of four phosphorylated-proteins in both cell lines: Phospholipase C gamma 1 (PLCγ1), Proline-rich tyrosine kinase 2 (PYK2), Endothelial nitric oxied syntase (eNos) and Signal transducer and activator of transcription 3 (STAT3 Y705), thus suggesting that these proteins are primary targets of HF. In addition, the protein target of rapamycin (TOR) was down-regulated only in THP-1, while the levels of STAT3 S727 and STAT5a/b were significantly decreased by HF treatment only in Kasumi-1 cells. This comparative analysis suggests that the sensitivity to HF may be dependent on inhibition of STAT3/5 pathway.
Summary/Conclusions: In summary, our results suggest that HF may be effective against core binding factor leukemias and, that the methodology based on a Phospho-Kinase Array is useful to identify drug molecular targets.

PB1663

DNA METHYLATION AND HYDROXYMETHYLATION PROFILING IS CAPABLE TO DISTINGUISH AML SAMPLES WITH DISTINCT MUTATIONS IN DNA METHYLATION REGULATORY GENES

H. Hájková[1,*], Š. Voráčková[1], Z. Krejčík[1], E. Cerovská[1], P. Cetkovský[2], C. Šálek[2]
[1]Department of Genomics, [2]Clinical Department, Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Aberrant DNA methylation as well as hydroxymethylation is a hallmark of acute myeloid leukemia (AML). Mutations of DNA methylation regulatory genes (DNMT3A, IDH1, IDH2 and TET2) are present in approximately 40-50% of AML. These mutations are often present together with the exception of TET2 and IDH1/2 as well as IDH1 and IDH2, which are usually mutually exclusive.
Aims: We aimed to perform DNA methylation, hydroxymethylation and gene expression profiling in clearly defined subgroups of AML patients with distinct mutations in DNA methylation regulatory genes to see whether there is a clear epigenetic and gene expression signature.
Methods: We accomplished DNA hydroxymethylation and methylation profiling in 12 AML samples at diagnosis and in CD34+ cells of 3 healthy controls by MethylationEPIC array (Illumina) covering aprox. 850 000 CpGs. AML samples were chosen based on their mutational status and divided into 4 groups: DNMT3A+ (n=3), IDH1+ (n=3), DNMT3A+/IDH1+ (n=3) and IDH2+ (n=3). The remaining DNA methylation regulatory genes as well as CEBPA were unmutated. 1 µg of genomic DNA was treated with TrueMethyl Seq kit (CEGX) to convert DNA through oxidative bisulfite (oxBS) and bisulfite (BS) treatment. This approach allows us to determine whether CpG is methylated or rather hydroxymethylated. We also performed gene expression profiling on the same samples by HumanHT-12 v4 Expression array (Illumina).
Results: We performed hierarchical clustering analysis of oxBS β-values (corresponding to DNA methylation levels) of 830 304 CpGs (with detection P<0.05) and observed clear separation of 4 groups according to mutational status – DNMT3A+, IDH1+, IDH2+ and CD34+ normals. Interestingly, double positive DNMT3A+IDH1+ (n=3) samples clustered each into different group (DNMT3A+, IDH1+, CD34+ normal) strongly suggesting that there is a cumulative effect of these two opposing mutations (Figure 1). We found out that genes hypermethylated in IDH1+ samples are enriched for genes from HOX gene family (P<0.0001) and that these genes are often hypomethylated in DNMT3A+ patients. In addition, we detected a subgroup of CpGs assigned to HOXA2, HOXA4, HOXA10, HOXB3, HOXC4 and HOXD3 genes that are hypermethylated in IDH1+, hypomethylated in DNMT3A+ and normally methylated in DNMT3+IDH1+ samples relative to CD34+ normals. Clustering of DNA hydroxymethylation values (resulting from subtraction of oxBS β-values from BS β-values) resulted into the same 4 main clusters as shown for DNA methylation data. DNMT3A+ patients displayed the lowest hydroxymethylation levels from all patients. Genes hydroxymethylated in IDH1+ patients were enriched for genes involved JNK cascade (comprising of evolutionarily conserved MAP kinases). The gene expression data did not reveal any cluster coherent with mutational subgroups, only CD34+ normals clustered together.

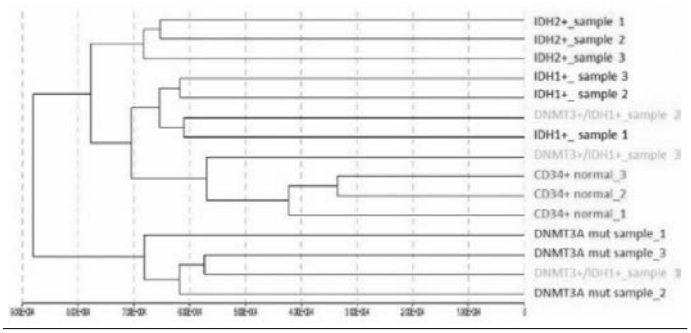

Figure 1.

Summary/Conclusions: We explored that AML patients with clearly defined mutational background exhibit distinct DNA methylation as well as hydroxymethylation profiles. The presence of two mutations that have the opposing effect on DNA methylation pattern (DNMT3A and IDH1) is linked to mixed DNA methylation patterns, which prevents unambiguous assignment to one cluster. Further, our data support that IDH1+ and IDH2+ represent distinct biological entities. On the contrary, gene expression profile did not support separation of samples into different mutational subgroups. We plan to enlarge the patients' cohort and validate the most promising genes involved in selected pathways.
Supported by Ministry of Health of the Czech Republic, grant nr. 15-25809A, and by the project for conceptual development of research organization (00023736) from the Ministry of Health of the Czech Republic.

RNA-MEDIATED CORRECTION OF ABERRANT DNA METHYLATION AT THE P15 LOCUS

M. Li[1,*], M. Borchiellini[1], P. Cascino[1], N. Habib[2], A. Di Ruscio[1]
[1]University of Eastern Piedmont, Novara, Italy, [2] Imperial College London, Hammersmith Campus, London, United Kingdom

Background: *P15* (a.k.a cell cycle dependent kinase inhibitor 2B; CDKN2B; INK4B) is a methylation sensitive gene located on chromosome 9p21 and commonly found silenced during Myelodysplastic Syndrome (MDS) progression to Acute Myeloid Leukemia (AML). *P15* encodes for a cyclin-dependent kinase inhibitor increasingly expressed during granulomonocytic maturation (Teofili *et al.*, *Exp Hematol* 2000). *P15* deletion or promoter methylation has been shown to independently correlate with disease progression and poor patient prognosis (Tien *et al.*, *Br J Hematol* 2001). Additionally, *P15* expression was also sensitive to regulation by myeloid-specific transcription factor PU.1 (Schmidt *Blood* 2004). As MDS evolution to AML includes both myeloid proliferation and blocked differentiation stages, restoration of the natural P15 transcript will provide not only valuable information regarding disease progression but may also alleviate some of their characteristic symptoms.
Aims: Currently available demethylating agents approved for therapeutic applications, *e.g.* 5-azacytidine and decitabine, have major side effects of high toxicity and non-specific DNA methylation that limit their clinical application. Therefore, the aim of this study is to achieve RNA-mediated correction of the aberrantly methylated *P15* locus using small activating RNAs (saRNAs; Li et al PNAS 2006).
Methods: Myeloid Leukemia cell lines HL-60, KG1a, and K562 were screened for basal p15 expression by western blotting and qRT-PCR. As the *P15* locus is also often deleted, deletion of the locus was assayed for by PCR and by Fluorescent *In Situ* Hybridization. Because the methylation status of *P15* was shown to be inversely correlated with ANRIL (Antisense Non-coding RNA in the INK4 Locus) expression (Kotake et al *Oncogene* 2010), p15 and ANRIL gene expression were measured in parallel. HEK293 cells serve as positive control in all studies. SaRNAs were designed against the proximal promoter, first exon, and intron regions of the *P15* gene body. SaRNAs were introduced to cell lines through electroporation, and re-activation of the locus was measured at the transcript level by qRT-PCR and protein level by western blotting. Changes in *P15* promoter level methylation were determined by Methylation Specific PCR.
Results: Transfection of saRNAs into the HL60 cell line showed upregulated p15 expression 24 and 48 hrs post-transfection. Analysis of ANRIL after saRNA-transfection showed no concomitant changes, suggesting locus-specific activity of the saRNAs. Future experiments will elucidate the mechanisms of saRNA activation of P15 gene expression and genome-scale specificity of saRNA-mediated methylation changes.
Summary/Conclusions: There is much interest in using RNA molecules as a therapeutic tool (Kole *et al.*, *Nat Rev Drug Discovery* 2012; Reebye *et al.*, *Hepatology* 2014). Introduction of such an approach offers greater advantages over

existing hypomethylating-based protocols: a) high gene specificity b) lower cytotoxicity and c) absence of drug based off-target side-effects. In the short term, this research can lead to the identification of novel key regulators of leukemogenesis and new targets for therapeutic treatments; in the long term pave the way for development of RNA-based gene demethylating agents for cancer treatment.

PB1665

JQ1 AND CURCUMIN COMBINED TREATMENT SHOWS SYNERGIC EFFECTS IN MLL-REARRANGED LEUKEMIA CELL LINES

P. Vitullo[1,*], P.P. Leoncini[1], V. Tocco[1], M. Pigazzi[2], K. D'Ovidio[1], D. Montagna[3], R. Rota[1], A. Bertaina[1]
[1]Oncohaematology, Bambino Gesù Children Hospital, Roma, [2]Pediatrics-Oncoematology, Univeristy of Padova, Padova, [3]Pediatrics, Policlinico San Matteo, Pavia, Italy

Background: MLL-rearranged leukemia accounts for □70% of infant and □10% adult acute leukemias, featuring a particularly poor prognosis and high risk of relapse. Our main field of study is AML, in which nearly 50% of total cases accounts for t(9;11) translocation, the remaining 50% predominantly includes t(6;11)(q27;q23), t(10;11)(p12;q23), t(11;19)(q23;p13.1) and t(11;19)(q23;p13.3). A 2% of AML total cases, however, is characterized by t(4;11) translocation, which is a marker of bad prognosis and it's, so far, poorly characterized. A key feature of MLL-rearranged leukemia is cMyc overexpression, a well-known oncogene involved in several types of cancer. JQ1 is a novel molecule, which prevents cMYC expression binding an important bromodomain protein, BRD4. Moreover, Curcumin, a natural compound, inhibits HATs enzymes preventing lysine 14 acetylation on histone H3 (AcH3K14), a particular residue which is bind by BRD4 to exert its function.
Aims: We would like to explore a potential synergic effect between JQ1 and Curcumin molecules in the attempt to develop a novel therapeutic alternative to standard chemotherapy and to deeply investigate features underlying the molecular pathogenesis in pediatric MLL-rearranged pediatric AML.
Methods: Four human leukemia cell lines with MLL fusion protein have been employed in this study: RS4:11, MV4:11 expressing MLL-AF4 and THP1, MOLM13 expressing MLL-AF9 fusion genes. 5μM and 10μM Curcumin were used to treat MLL-AF4 and MLL-AF9 cell lines respectively, while 250nM JQ1 was used to treat all the cells lines. After 2 days of treatment, either with single and combined drugs, cell number quantification, based on metabolic activity, was detected through XTT assay. In order to assess the cMYC, CDKN1A, BCL2 transcripts levels and mir-99a expression a quantitative RT-PCR analysis was carried out, while we used western blotting to detect the expression of cMYC, PARP, Caspase3 and AcH3K14. Apoptosis and cell cycle were evaluated by flow cytometric analysis.

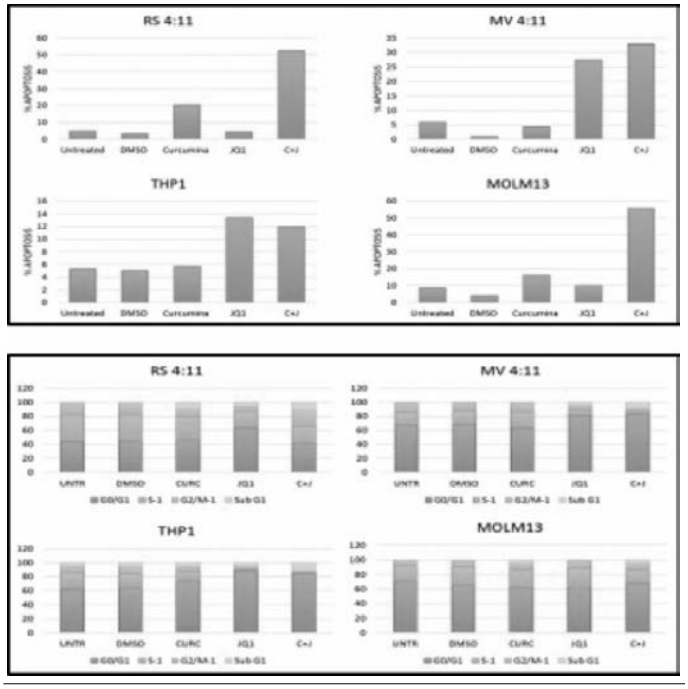

Figure 1.

Results: In apoptosis analysis, a synergic effect was detected for all 4 cell lines, similarly cell cycle evaluation showed a significant accumulation of cells at SubG1 phase (2-8 fold) (Figure 1). XTT metabolic assay showed a reduction in proliferation percentage: 65±5 for curcumin and JQ1 single treatment and 59±5 for combination of drugs in both MLL-AF4 cell lines, meanwhile in MOLM13 cells it was 64±2 and 87±2 for curcumin and JQ1, respectively and 76±2 for their combination (P<0.005). The THP1 cells did not shown any significant modulation in the proliferation. We decided to focus our study on t(4:11) translocated cells, considering the more intense effect of the combined drugs on previous analysis. qRT-PCR and western blot experiments revealed a synergic effect of the 2 experimental drugs on both apoptosis and proliferation gene related (bcl2, caspase3, Parp, cdkn1a) as well as on the direct targets of the drugs (cMyc, AcH3K14). Finally, in MLL-AF4 cell lines, curcumin and JQ1 together induced a significant decrease in mir-99a expression.
Summary/Conclusions: Our data demonstrated that curcumin and JQ1, inhibiting HATs and BRD4 respectively, exert a more intense synergic effect on MLL-AF4 than in MLL-AF9 cells. Increased apoptosis together with a reduced proliferation rate, prompted us to investigate on molecular pathway in which targets of these drugs are involved. Intriguingly, we found a significant decrease in cMyc, bcl2 and AcH3K14 expression, confirming that both curcumin and JQ1 have a synergic effect. Additionally, we revealed a significant reduced expression of mir-99a, a well know oncomiR reported to act as negative regulator of differentiation and involved in drug-resistance, typically upregulated in pediatric AML and ALL.

PB1666

TP53B AND TP53Γ EXPRESSION LEVELS IN RELATION TO NPM1 AND CEBPA MUTATIONS.

K. Matiakowska[1,*], A. Bartoszewska-Kubiak[1], E. Bielinska[1], M. Morgut-Klimkowska[1], O. Haus[1]
[1]Department of Clinical Genetics, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Torun, Bydgoszcz, Poland

Background: Acute myeloid leukemia (AML) is a heterogeneous clonal disorder with the presence of diverse genetic abnormalities in hematopoietic stem cells. The most frequent alterations in normal karyotype AML (NK AML) are mutations in exon 12 of nucleophosmin gene (*NPM1*). Until now 56 different mutations of *NPM1* exon 12 have been described, mostly insertions. The NPM protein plays an important role in cell cycle and apoptosis control. It cooperates with several proteins, among them with p53 and ARF. The median levels of functional nuclear p53 protein are reduced in *NPM1* and *FLT3 ITD* mutant samples. *TP53* encodes a tumor suppressor protein which consists of transactivation, DNA-binding and oligomerization domains. Due to alternative splicing it may exist in 13 different isoforms. Alternative splicing of intron 9 leads to production of 2 different proteins, p53β and p53γ, without oligomerization domain (stop codon is localized in exon 9b). These isoforms can be present in acute myeloid leukemia (AML) cells. p53β binds to *BAX* promoter and can induce apoptosis independent from p53 wt. p53 has influence on activation of *CEBPA* which is associated with cell cycle regulation, especially cell cycle arrest and plays also role in cell differentiation. Generally, it is a transcription factor expressed during myeloid lineage development, from progenitor cells to mature granulocytes. Various mutations of *CEBPA* gene are described. Among them N-terminal and C-terminal mutations, mostly insertions and deletions, are often present.
Aims: The goal of the study was to assess mutational status of *NPM1, CEBPA* and *FLT3* in association with *TP53*beta and *TP53*gamma expression evels.
Methods: 75 NK AML patients were included in the study. *NPM1, CEBPA* and *FLT3* gene mutations were analyzed by direct sequencing. *TP53*β and *TP53*γ expression levels were assessed with real time PCR. Expression levels were analyzed with ΔΔCt method, with *ABL* as a control gene and K562 cell line as a calibrator.
Results: In all 75 cases, *TP53*β and *TP53*γ transcripts were detected. 36 patients had *NPM1* mutations, 25 had *CEBPA* mutations or known polymorphisms, and 25 had *FLT3* ITD mutation. Assessed median expression level of *TP53*β was much higher (ΔΔCt 43,11) than *TP53*γ (ΔΔCt 10,85; p<0,05). Furthermore, expression level of *TP53*γ in *CEBPA* mutated group (ΔΔCt 11,4) was significantly lower than in *CEBPA* wt group (ΔΔCt 17,7) (p=0,03). We have not found any other important correlation between mutations of studied genes and *TP53*γ or *TP53*β expression. We also classified patients, according to median expression value of *TP53,* to two groups: with overexpression or with low expression. Haematological and clinical features, such as white blood cells count (WBC), blasts count in bone marrow or patient age did not depend on *TP53* isoform expressions. However, statistical analysis showed important difference between WBC count in *NPM1*mutated and *NPM1*wt groups.
Summary/Conclusions: Obtained results may suggest a clinical importance of simultaneous analysis of *TP53* isoform expression and mutations in *CEBPA* gene. It may be hypothesized that a changed sequence of the latter gene might influence *TP53* isoform expression and in consequence regulate the cell cycle.

PB1667

EXPRESSION PROFILE OF EPIGENETIC MODULATORS IN ACUTE MYELOID LEUKEMIA OF INTERMEDIATE RISK

C. Bilbao Sieyro[1,2,*], Y. Florido Ortega[1], C. Rodríguez Medina[1], S. Gamrani[1],

E. Molina Hoyo[3], S. Sánchez Sosa[1], S. De la Iglesia Iñigo[1], M.T. Molero Labarta[14], G. Santana Santana[1], M. Perera Álvarez[1], S. Jiménez Bravo de Laguna[1], M. T. Gómez Casares[1]
[1]Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, [2]Morfología, Universidad de Las Palmas de Gran Canaria , Las Palmas de Gran Canaria, [3]Department of Molecular and Cellular Signalling , Institute of Biomedicine & Biotechnology of Cantabria , Santander, [4]Ciencias médicas y quirúrgicas, Universidad de Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain

Background: Whole-genome sequencing has revealed acute myeloid leukemia (AML) as a very complex and dynamic disease.Epigenetic modulation is among the functional categories of the mutational landscape in AML.According to recent reports, suppression of the epigenetic reader BRD4 with small-molecule inhibitors (BET-i) results in antileukemic activity. Clinical trials are being developed, however, so far, identification of those patients that may benefit from this therapy is not possible as changes in mRNA BRD4 levels seem to be very subtle. It has been recently suggested that antileukemic effect of BET-i could be due to c-myc suppression and also that high Bcl-2 levels may target those patients that would benefit of BET-i. We believe that establishing the expression profile of epigenetic modulators in AML may help in the identification of patients that could benefit from BET-i.
Aims: We wanted to get a better insight regarding the expression profile of epigenetic modulator in AML of intermediate risk by studying: 1)expression levels of EZH2, ASXL1, BRD4, c-myc and Bcl-2 in a consecutive series of AML patients; 2) correlation between mRNA and protein levels; 3) Determining BRD4 binding to the c-myc promoter through chromatin immunoprecipitation (CHIP).
Methods: Our series consisted of 104 consecutive patients with a mean age of 55.8 years (range 15-79 years) diagnosed and treated between 2005-2016 at the Hospital Universitario de Gran Canaria Dr. Negrín with a median follow up of 12 months. Gene expression analysis was carried out through real time PCR in a LightCycler 480 Instrument II (Roche) using GUS a control gene.Results were normalized with a cDNA pool from bone marrow of 10 healthy donors which was introduced as internal control in each experiment. Western blot were performed to determine protein levels for BRD4, c-myc and Bcl2. CHIP studies for BRD4 were carried out in HL60 cell line. For statistical analysis the SPSS (v.15.0) software was used.
Results: ASXL1 levels were positively associated with EZH2 (Spearman's= 0.285, p=0.021) and BRD4 withc-myc (Spearman's coefficient=0.420, p<0.001), Bcl2 (Spearman's= 0.471, p<0.001) EZH2 (Spearman's= 0.4565, p=0.008) and ASXL1 (Spearman's=0.949, p<0.001). Survival analysis considering 50th percentile as a cut-off value for BRD4 expression indicated that patients with higher levels shows better overall survival (median overall survival, OS, of 27 months, 95% IC 15.1-38.9) compared to those with low expression (median OS 12 months, 95% IC 0.4-23.7), although the association was not statistically significant (p=0.196) probably due to the limited series size. Protein levels of Bcl2 and c-myc correlated with those of mRNA, but not for BRD4, although other antibodies should be tested in order to confirm these results. CHIP analysis in HL60 cell lines confirmed the binding of BRD4 to c-myc promoter.
Summary/Conclusions: The positive association observed between EZH2 and ASXL1 agrees with the fact that both cooperate in the epigenetic repressive complex PRC2.The association of BRD4 expression levels with c-myc and Bcl2 is in accordance to the reported binding of BRD4 to the c-myc and Bcl2super-enhancer regions and our CHIP analysis also support so. Further studies in a larger series are necessary to confirm the relationship between higher BRD4 levels and better overall survival. Finally, future analysis should be done to determine whether patients with higher BRD4 expression levels determine a subgroup with better response to BET-i.

Background: CEBPA is a transcriptional co-factor of RUNX1 which play a major role in the fate decissions associated with physiologic myelopoiesis. Biallelic CEBPA mutations (dm) define an homogenous molecular subgroup which is associated with a favorable outcome. CEBPA mutations may be transmitted in the germ line giving rise to clusters of familial leukemias.
Aims: To analyze the immunophenotypic findings assessed by multiparametric flow cytometry in a consecutive series of *de novo* CEBPAdm AML.
Methods: Thirty-nine adult patients with *de novo* AML and CEBPAdm who where enrolled on the AML-03 and AML-12 protocols of the Spanish CETLAM cooperative group were included in this study The immunophenotypic analysis was performed on erythrocyte-lysed bone marrow (BM) samples obtained at diagnosis. Antigenic expression of leukemic cells was systematically analyzed by multiparametric flow cytometry using four-color staining. The antigens studied were: CD45, CD34, HLA-DR, CD10, CD20, CD19, CD2, CD33, CD7, CD117, CD66, CD13, CD64, CD36, CD56, CD14, CD123, CD61, CD42b, glycophorin, CD71, CD11b, myeloperoxidase, CD79a, CD3, TdT, lysozyme and lactoferrin. At least 10.000 events/tube were measured. Analytical gates were established according to CD45 reactivity and to FSC/SSC pattern.Positivity thershold was established at 20%. The FACS-DIVA,Paint-a-Gate and Infinicyt software programs were employed for analysis. Amplification of overlapping PCR products covering the whole CEBPA coding sequence followed by Sanger sequencing were used to investigate CEBPA mutations. FLT3-ITD, NPM1, MLL-PTD, WT1 and GATA2 mutations were also investigated by conventional PCR-based molecular methods.
Results: Antigen reactivity was as follows: CD45 (39/39,100%), CD15 (35/39, 90%), CD34 (36/39,92%), HLA-DR (39/39,100%), CD33(39/39,100%), CD2 (2/39,5%), CD7 (36/39,92%),CD117(39/39,100%), CD13(37/39,95%), CD56 (6/39,15%), CD36 (6/39, 15%), CD123(39/39, 100%), CD14 (1/39,0.02%), CD71(38/39,97%), myeloperoxidase (38/39, 97%).In nine cases CD36 and/or CD56 expression on leukemic blasts was greater than 20% Those CD36/CD56+ cases had a shorter overall survival and leukemia free survival (see graph). Four out five tested CD36/CD56+ cases also showed GATA 2 mutations. An additional CD36/CD56+ case had a FLT3-ITD. In three out 39 cases (7%) a population showing cytoplasmic CD79a reactivity was detected (8%, 11%,14% of the neoplastic population, respectively). Two of those cases had also a FLT3-ITD.

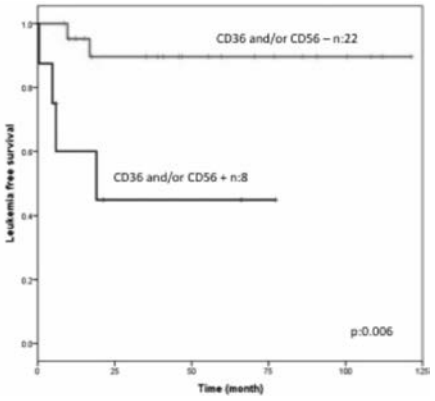

Figure 1.

Summary/Conclusions: CEBPAdm cases showed an homogeneous immunophenotype with positivity for CD45, CD7,CD34,CD123,CD117, HLA-DR, CD71,CD33,CD13 and CD15. CD36 and/or CD56 overexpression was detected in a subgroup of cases (9/39, 23%) with an adverse outcome. The current findings suggest that CD36 and CD56 reactivity should be investigated in larger series of CEBPAdm AML cases. Small leukemic populations with B-cell markers are not uncommon in CEBPAdm AML (3/39, 7%).

PB1669

PROTEOME CHANGES IN ACUTE MYELOID LEUKEMIA PATIENTS BEFORE AND AFTER INDUCTION TREATMENT

L.F. Restrepo Rodríguez[1,*], S. Rothlisberger[1]
[1]Biomedical Engineering, Instituto Tecnologico Metropolitano, Medellín, Colombia

Background: Acute myeloid leukemia (AML) is a malignant disorder of hematopoietic stem and progenitor cells (HSPCs), characterized by the accumulation of immature blasts in the bone marrow and peripheral blood (PB) of affected patients. Standard induction therapy, based on cytarabine and an anthracycline, leads to complete remission in approximately 50% to 75% of patients, depending on prognostic factors, such as age or the presence of certain gene or chromosomal changes. In spite of favorable primary response rates, only approximately 20% to 30% of the patients enjoy long-term disease survival.
Aims: Our aim was to compare the protein expression profile of peripheral blood mononuclear cells (PBMCs) of AML patients at time of diagnosis and after induction therapy.
Methods: PB samples were taken from seven AML patients in Medellin-Colombia at time of diagnosis and after concluding the induction therapy. Informed consent was obtained prior to sample collection. PBMCs were isolated from the 14 blood samples using a Histopaque-1077 solution. Cells were resuspended in lysis buffer (0.5% Triton x-100, 50 mM Tris-HCL pH 8.0, 150 mM NaCL, 1 mM EDTA, protease inhibitor) and proteins precipitated with trichloroacetic acid. Proteins were separated by 2D SDS-PAGE (pI 3–10 NL), and stained with SYPRO®Ruby. The proteomes were compared using PDQuest™ Advanced 8.0.1 Software. Protein spots of interest were those with a fold change of +/- 1.5 and p <0.05.

Results: Image analysis revealed an average of 464 protein spots in PB samples taken at time of diagnosis, and an average of 346 spots in PB taken after induction therapy, reflecting changes in protein expression due to treatment. Comparing the proteomes, we found 11 spots that differed significantly (fold change of +/- 1.5 and p <0.05). Of these, seven proteins were up-regulated and four were down-regulated at time of diagnosis (before treatment) compared to after induction treatment. Nine of these spots correspond to low molecular weight proteins (<40 kDa) and 2 spots have a molecular weight between 40-60 kDa. Based on the molecular weight and isoelectric point information of these spots we were able to search for proteins reportedly involved in leukemia, in order to propose possible identities (see Table 1). In terms of biological process, four proteins (eIF5B, HSP27, 14-3-3 protein zeta/delta, and GST-P) are involved in the regulation of apoptosis. The F-actin-capping protein subunit beta could also be of interest, as reorganization of F-actin reflects unique characteristics of the differentiation process in promyelocytic leukemia cells. RuvB-like 2 is a positive regulator of histone acetylation and DNA repair. GRBP2 is a protein involved in the MAPK cascade and regulation of PI3K signaling, pathways regulating diverse cellular functions altered in leukemogenesis such as proliferation, differentiation, and apoptosis. Alpha-enolase is a key glycolytic enzyme; however, it has been shown to be a multifunctional protein involved in cancer. It promotes cell proliferation by also regulating the MAPK and PI3K pathways. Transaldolase is part of the pentose-phosphate pathway. Annexin II acts in angiogenesis and has multifaceted role in human health and disease.

Table 1.

Possible protein identity of spots with differential expression

Spot	Possible Identity	Uniprot AC	Experimental		Theoretical		Fold change	GO - Biological process
			MW	pI	MW	pI		
1	Eukaryotic translation initiation factor 5A-1 isoform B	P63241	16,48	4,43	17	5,08	2,6	Regulation of apoptotic process.
2	HSP27	P04792	22,74	3,39	22	5,98	4,0	Negative regulation of apoptotic process.
3	14-3-3 protein zeta/delta	P63104	27,01	4,2	27	4.73	-5,6	Negative regulation of apoptotic process.
4	Glutathione S-transferase P	P09211	24,46	5,39	23	5.43	2,7	Negative regulation of apoptotic process.
5	F-actin capping protein subunit beta	P47756	30,27	5,19	30	5,69	-2,0	Actin cytoskeleton organization, regulation of cell morphogenesis.
6	RuvB-like 2	Q9Y230	51,81	5,44	51	5.49	2,4	Positive regulation of histone acetylation, DNA repair.
7	Growth factor receptor bound protein 2	P62993	26,32	6,12	25	5.89	1,8	MAPK cascade, regulation of PI3K signaling.
8	Transaldolase	P37837	37,33	6,94	37	6.36	1,8	Carbohydrate metabolic process, pentose-phosphate shunt.
9	Annexin II	P07355	38,02	8,01	38	7.57	-3,9	Angiogenesis, positive regulation of fibroblast proliferation.
11			38,2	8,23			-3,3	
10	α- enolase	P06733	48,14	7,4	47	7.01	4,6	Negative regulation of cell growth, negative regulation of transcription.

Summary/Conclusions: The protein expression profile of AML patients changes after induction treatment. We found 11 spots that differed significantly, and propose possible identities for these. Further analyses are pending in order to experimentally establish the identities and correlate with response to treatment.

PB1670

AMP-ACTIVATED PROTEIN KINASE ACTIVITY INTERFERES WITH OVEREXPRESSION OF NUCLEOPHOSMIN IN CYTARABINE-INDUCED CHEMORESISTANT AML CELLS

D. Kim[1,2,*], K.N. Kim[1,2], J. Kang[1,2], C.S. Park[1,2], H.G. Yi[3]
[1]Hypoxia-related Disease Research Center, [2]Pharmacology, [3]Internal Medicine, Inha University School of Medicine, Incheon, Korea, Republic Of

Background: Cytarabine is a chemotherapeutic drug used alone or in combination with other anticancer drugs to treat acute myeloid leukemia (AML). New treatment strategies are emerging to enhance the anti-cancer effect and decrease the toxiciteis. Nucleophosmin (NPM1 or B23) is a ribosomal protein located mainly in nucleolus, and multifunctional enzyme in cancer cell growth and protein synthesis. AMP-activated protein kinase (AMPK) is a critical energy sensor to regulate homeostasis and plays a potential role for anti-cell proliferating activity.
Aims: We investigated the effects of AMPK activation on the cell death (apoptosis) and NPM1 expression in AML cells treated with low or high dose of cytarabine, an anti-leukemic drug, to predict the mechanisms responsible for AML cells chemoresistance.
Methods: The HL-60 (FAB M2) cells were exposed to the different drug combinations including cytarabine and AMPK activators. The molecular mechanisms of drug synergism detected by western blot assay and RT-qPCR. Cell viability and apoptosis were assessed using cell counting kit - 8 assay and flow cytometry.
Results: We found that cell apoptosis (36.27 ~ 42.11%) showed little dependence on cytarabine concentrations (10, 100, and 1000 mM), while the overexpression of NPM1 increased proportionally with drug dependence, indicating the drug-induced cell resistance. In the same point, cytarabine also inhibited the phosphor-activity (Thr172) and expression level of AMPK, which has mTOR-p70S6K pathway-repressor activity. As expected, single cytarabine treatment increased the ratio of p-mTOR/mTOR and p-p70S6K/p70S6K. Co-treatment of AMPK activator (phenformin or AICAR) in cytarabine-treated HL-60 AML cells inhibited significantly the induction of NPM1 overexpression level with the decrease of phosphor-activities of mTOR and its substrate p70S6K, resulted in the accelerated cell apoptosis.
Summary/Conclusions: Our results suggest that the higher concentration of cytarabine induces NPM1 overexpression, and that AMPK activation might be used to sensitize AML cells to cytarabine with the control of NPM1 expression levels. These modulatoins to standard therapeutic strategies could actually enable the reduction of the chemotherapeutic dose, therefore reducing their toxicity and adverse effects.

QUERCETIN REGULATES TELOMERE-BINDING PROTEINS EXPRESSION OF POT1, TRF1, TRF2 TO INHIBIT PROLIFERATION AND INDUCE APOPTOSIS IN AML THP-1 CELLS

S. Cui[1], X. Wu[2], Z. Wang[1], Y. Guo[2], R. Xu[1,*]
[1]Hematology Department, Affiliated Hospital of Shandong University of TCM, [2]The 1st Clinical College , Shandong University of TCM, Jinan, China

Background: Leukemia cells are limitless cell sources for initiation and maintenance of leukemia. Telomere-binding proteins are key regulatory factors for various diseases, including leukemia. Therefore, targeting telomere-binding proteins is considered as a promising therapeutic strategy for treatment of leukemia.
Aims: We aimed to explore whether quercetin, a natural flavonoids, could regulate telomere-binding proteins expression to inhibit proliferation and induce apoptosis in acute myeloid leukemia(AML) THP-1 cells.
Methods: 1. *In vitro*: (1) We cultured human AML THP-1 cells. (2) The cells were treated with different concentration of quercetin for 24/48 h, and the cell viability was measured by cell counting kit-8(CCK-8) to determine the IC50 of quercetin. (3) The cell cycle distribution and apoptotic rate were measured by Annexin V-FITC/PI double staining flow cytometry(FCM). (4) The protein expression levels of POT1, TRF1, TRF2 were measured by western-blotting. (5) The mRNA expression levels of POT1, TRF1, TRF2 were measured by real-time fluorescent quantitative polymerase chain reaction(RT-qPCR). 2 *In vivo*: (1) Established AML-NOD/SCID model based on THP-1 cell line in NOD/SCID mice, and treated with optimal quercetin concentration 40mg/(kg*d) for 4 weeks by tail vein injection. (2)We observed the changes of mice survival status, peripheral blood and bone marrow cell morphology and organ histopathology by microscopy before and after treatment with quercetin. (3) The cell cycle distribution and apoptotic rate of spleen cells were measured by Annexin V-FITC/PI double staining FCM. The protein expression levels of POT1, TRF1, TRF2 were measured by immunohistochemistry(IHC) staining.
Results: In this study, we found that quercetin significantly suppressed THP-1 cells proliferation in dose- and time-dependent manner. Treatment with quercetin significantly increased THP-1 cells apoptotic rate and G1 phase arrest rate. Furthermore, the protein expression levels of POT1 and TRF1 increased and the protein expression level of TRF2 decreased. The mRNA expression levels of POT1, TRF1, TRF2 were consistent with their protein expression levels, respectively.
Summary/Conclusions: Our results demonstrate that quercetin has anti-leukemia activity. It is mediated by regulating telomere-binding proteins expression of POT1, TRF1 and TRF2. Taken together, our findings support the concept that quercetin is a promising therapeutic strategy for treatment of leukemia.

PPARΓ AGONISTS INHIBIT ADHESION SIGNAL TO ENDOTHELIAL CELLS IN THE DIFFERENTIATION INDUCTION OF HL-60 ACUTE PROMYELOCYTIC LEUKEMIA CELLS.

J. Park[1,*], E.-M. Noh[2], J.-W. Yoon[3], O.-Y. Hong[2], J.-S. Kim[2]
[1]Division of Hematology/Oncology, Department of Internal Medicine, Gachon University Gil Hospital, Incheon, [2]Biochemistry, Institute for Medical Sciences, Chonbuk National University Medical School, Jeonju, Korea, Republic Of, [3]Psychology, Fullerton College, Fullerton, United States

Background: All-*trans* retinoic acid (ATRA) has successfully been used in the treatment of acute promyelocytic leukemia (APL) patients, with a remission rate of greater than 90% .
Despite the high cure rates, induction mortality is a still a problem in APL. One of the most common causes of death was the differentiation syndrome (DS) . The early administration of high-dose dexamethasone at the onset of the first

signs or symptoms of DS is crucial, however specific biological therapies to counteract the syndrome are still not available.
Peroxisome proliferator activated receptor gamma (PPARγ) is a ligand-dependent transcription factor and a member of the nuclear receptor superfamily, which is expressed in normal monocytes, various leukemias, and epithelial malignancies. PPARγ is highly induced in differentiating myeloid cells and subsequently contributes to their differentiation.
Differentiation induction of APL cells is associated with increased expression of specific adhesion molecules and inflammatory cytokines, which may promote activation, migration, and adhesion of these cells.
Aims: Here, we studied the effect of PPARγ agonists on the adhesion of a human leukemia cell line (HL-60) to endothelial cells.
Methods: Differentiation was determined by an increase in reactivity with the CD11b antibody. For the adhesion assay, the Matrigel transwell system was used.
Results: HL-60 cells were differentiated into macrophage-like cells by a PKC activator, 12-*O*-Tetradecanoylphorbol-13-acetate (TPA). During the differentiation of HL-60 cells, PPARγ agonists acitvate TPA-induced CD11b expression. However, PPARγ agonists completely blocked TPA-induced ICAM-1 expression of endothelial cells, which resulted in the inhibition of adhesion of HL-60 cells to endothelial cells. These responses also were reversed by PPARγ antagonist (GW9662), indicating that PPARγ agonists inhibits the adhesion of the HL-60 cells to endothelial cells through a PPARγ dependent mechanism.
Summary/Conclusions: These results suggest that PPARγ agonists inhibit TPA-induced adhesion signal in the between HL-60 cells and endothelial cells, and may control differentiation syndrome in APL patients.

IN VITRO DRUG SENSITIVITY TEST IN THE INDIVIDUALIZED ANTI-LEUKEMIA CHEMOTHERAPY FOR THE NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

S.-N. Lim[1,*], W.S. Lee[2], J.-G. Shin[3], E.-Y. Kim[4], M.-K. Oh[3], H.-J. Shin[5], H.S. Lee[6], S. M. Lee[2]
[1]Internal Medicine, Haeundae Paik Hospital, [2]Internal Medicine, Busan Paik Hospital, [3]Pharmacology, [4]Clinical Pharmacology, Inje University College of Medicine, [5]Internal Medicine, Pusan National University Hospital, [6]Internal Medicine, Kosin University Gospel Hospital, Busan, Korea, Republic Of

Background: The biological properties, genetic abnormalities of leukemic cells influence on their sensitivity to chemotherapeutic drugs. It is widely known that there can be significant differences both in genetic features as well as in drug resistance profile of individual tumors with the same phenotype.
Aims: The purpose of this study was to analyze the relationship between *in vitro* chemosensitivity test results using the Cell Titer-Glo assay and clinical response on chemotherapy, and to find the possibility of optimizing the treatment for individual patients according to their actual drug resistance.
Methods: For The Cell Titer-Glo assay, we obtained bone marrow aspirates or peripheral blood samples from 68 patients with newly diagnosed acute myeloid leukemia at the time of initial diagnosis. The following drugs were tested: cytarabine arabinoside, daunorubicin, idarubicin, fludarabine, etoposide, and methotrexate. We evaluated clinical response and survival outcome according to chemosensitivity of drugs and protein expression.
Results: In this study, *in vitro* chemosensitivity test with the Cell Titer-Glo assay showed the relationship between chemosensitivity and survival outcome significantly. The 5-year overall survival rates with dichotomized chemosensitivity of idarubicin (64.6% *vs* 33.3%, p=0.046), cytarabine (63.1% *vs* 43.3%, p=0.0291), and fludarabine (80.1% *vs* 37.5%, p= 0.020) were higher in low centration level than in high concentration level. There was a tendency of higher relapse-free survival rate at 4-year in the patients with low level IC_{50} than in the high level IC_{50}. However, cytotoxic effect of testing drugs *in vitro* by the Cell Titer-Glo assay did not show a relationship with complete remission rate after induction and leukemia recurrence rate.
Summary/Conclusions: Although the Cell Titer-Glo assay did not provide the prediction of clinical response of induction treatment, it can be a useful tool in individually optimizing the chemotherapy of patients with newly diagnosed acute myeloid leukemia.

PB1674

PROGNOSTIC IMPACT OF P53 EXPRESSION IN BONE MARROW BIOPSY OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

H. Souza[1,*], S. Saad[1], I. Lorand-Metze[1], B. Duarte[1], G. Hayakawa[1], P. Campos[1], M. Delamain[1], G. Duarte[1], J. Vassallo[1], K. Pagnano[1]
[1]University of Campinas, Campinas, Brazil

Background: Several studies have shown that the presence of the *TP53* mutation is related to an unfavorable prognosis in patients with acute myeloid leukemia (AML). However there are few reports on the evaluation of its expression by immunohistochemistry in bone marrow (BM) biopsy.
Aims: To evaluate the expression of p53 in BM biopsy of AML patients at diagnosis and its impact on survival.
Methods: This retrospective analysis included 85 patients with *de novo* AML diagnosed from January 2005 to December 2015 submitted to BM biopsy at diagnosis. p53 expression was detected by immunohistochemistry, and staining was evaluated using the H-score (range 0-300). The t-test and Mann-Whitney U test were used to detect differences in the distribution of continuous parametric and nonparametric variables, respectively. Overall survival (OS), disease-free survival (DFS) and event-free survival (EFS) were calculated using the Kaplan-Meier method. The log-rank test was used for comparison of survival curves. The interaction between the examined prognostic variables was tested with univariate and multivariate Cox regression analysis.
Results: Median age was 60 years (17-81). There was a predominance of patients >60 years (54.1%) and males (56.5%). The median H-score for p53 was 11.8 (0.4-161.1), with no significant correlation with age or cytogenetic risk. p53 expression was significantly higher in patients with a complex karyotype (p=0.0031) and high risk by European Leukemia Net (ELN) criteria (p=0.047). There was a positive correlation with complex karyotype and prognostic risk by ELN. Excluding early deaths (<30 days from induction), patients younger than 60 years with H-score >60 showed worse overall survival when compared with patients with H-score <60 (0% *vs* 14.6%, respectively) (p=0.048). There was no statistical difference in disease-free survival and event-free survival. In the Cox univariate analysis including all cases, peripheral leukocyte counts at diagnosis (p=0.014), cytogenetic risk groups (p=0.07), ELN risk categories (p=0.023) and H-score (p=0.025) were significant. In a multivariate model including leukocytes, ELN risk and p53, all variables remained in the model.

Summary/Conclusions: Expression of p53 assessed by immunohistochemistry is a fast, objective and promptly available tool for prognostic evaluation of AML. A high expression of p53 (H-score >60) was related to a lower overall survival in *de novo* AML.

PB1676

LONG-TERM FOLLOW-UP OF SALVAGE TREATMENT FOR RELAPSED AML WITH CLADRIBINE, HIGH DOSE CYTARABINE AND IDARUBICIN

K. Mayer[1,*], C. Hahn-Ast[1], K. Schwab[1], A. Glasmacher[1], I. Schmidt-Wolf[2], P. Brossart[1], M. von Lilienfeld-Toal[1]
[1]Medical Clinic III, [2]University Hospital Bonn, Bonn, Germany

Background: Despite improving response rates in induction treatment for AML during the last years the outcome for relapsed or refractory AML is still poor. Currently, no standard therapy exists for patients with relapsed AML. Furthermore, CR rates are lower than in newly diagnosed patients and range between 15% and 50%. There is evidence that cladribine (2CdA) has single drug activity in AML as well as an enhancing effect on other cytostatic drugs such as cytarabine (AraC) and thus may help to overcome resistance mechanisms.
Aims: Therefore, testing the combination of 2CdA, AraC and idarubicin (CAI) seems reasonable. Here we present the final analysis from our single-center phase II trial evaluating the safety and efficacy of CAI in relapsed AML patients after a follow-up of 5 years.
Methods: Patients with relapsed AML after at least 6 months of remission and ECOG 0-2 were included. Chemotherapy regime consisted of two courses of 2CdA 5 mg/m²/12 h, d 1-3, AraC 1000 mg/m²/12 h, d1-3 and Idarubicin 8 mg/m²/d, d1-3. After 8 patients, the prolonged duration of neutropenia especially in course 2 prompted us to change the protocol by 1) application of growth factors from day 15 onwards, and 2) omission of idarubicin from the 2nd course. The primary endpoint was the overall remission rate and safety of CAI.
Results: Because of slow recruitment the study was stopped after 20 patients. The median age was 63 years, 40% were female. 19/20 (95%) patients were included in the first relapse after at least 6 months of CR following 1st line therapy for AML. 1/20 (5%) patient was included with a second relapse. In 14/20 patients cytogenetic data at the timing of relapse were available, according to the ELN-risk-group 2017 3/14 (22%) had favourable cytogenetic changes, 9/14 (64%) intermediate and 2/14 (14%) belonged to the adverse cytogenetic group. The performance status was good in most patients (ECOG 0 in 10%, ECOG 1 in 80%), but reduced (ECOG 2) in 2 (20%) patients. After the first course, CR/CRi was achieved in 60% and PR in 10% of patients. Median duration of neutropenia was 24 days (range 18-41d). The main grade 3 or 4 non-haematologic toxicity was infection seen in 85% of courses. Nausea occurred in 30%, hepatotoxicity, mucositis and diarrhea in 11% of courses. Cardiac or renal toxicities grade 3/4 were not observed. Two patients (10%) died due to infection. Six patients received a second course of CAI/CA. Altogether, 6 patients were refractory. Nine patients (48%) proceeded to allogeneic stem cell transplantation after induction therapy with CAI. Of those, 4 patients are still alive and free of leukemia and one patient died in CR 88 months after salvage-therapy accounting for a 5-year survival rate of 55%.
Summary/Conclusions: Combination therapy with CAI in relapsed AML patients is feasible and induces good response rates. Combined with allogeneic stem cell transplantation, long-term survival can be achieved. However, infection rates are a serious complication warranting intensive supportive care.

PB1677

HIGH EVI1 EXPRESSION PREDICTS POOR OUTCOMES IN ADULT ACUTE MYELOID LEUKEMIA PATIENTS WITH INTERMEDIATE CYTOGENETIC RISK RECEIVING CHEMOTHERAPY ONLY

Y.-Z. Qin[1], T. Zhao[1], H.-H. Zhu[1], J. Wang[1], J.-S. Jia[1], Y.-Y. Lai[1], X.-S. Zhao[1], H.-X. Shi[1], Y.-R. Liu[1], H. Jiang[1], X.-J. Huang[1], Q. Jiang[1,*]
[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China

Background: Nearly half of acute myeloid leukemia (AML) patients are defined as an intermediate cytogenetic risk, however the patients in this group have greatly varied outcomes and need to be stratified. Apart from gene mutation, abnormal gene expression might also be prognostic, and ecotropic viral integration site 1 (EVI1) expression is a representative. To date, the poor prognostic impact of EVI1 expression in AML has been reported, but almost all studies have been undertaken by European researchers. EVI1 prognostic significance in AML remains to be confirmed in other populations. Furthermore, because the detection protocol and cutoff value selection methodologies differed among studies, the threshold for defining EVI1 high expression remains obscure, which hinders its clinical routine application.
Aims: We investigated the prognostic impact of EVI1 transcript levels in Chinese adult intermediate cytogenetic risk AML (ICR-AML) patients who received chemotherapy only in a single center. The appropriate cutoff values for grouping EVI1 expression were also evaluated.
Methods: A total of 191 adult patients receiving chemotherapy only were included in this study. They were diagnosed as ICR-AML according to morphology, immunophenotyping, cytogenetics and molecular biology. Their bone marrow samples were collected at diagnosis. Real-time quantitative PCR was performed to test EVI1, MLL partial tandem duplicate (MLL-PTD) and WT1 transcripts, and their transcript levels were calculated as the percentage of target transcript copies/ABL copies. NPM1 mutations and FLT3 internal tandem duplication (FLT3-ITD) were individually screened by real-time quantitative PCR and qualitative PCR. 27 normal bone marrow (NBM) samples form volunteers were simultaneously tested EVI1, MLL-PTD and WT1 transcripts. All participants provided written informed consent in accordance with the Declaration of Helsinki.
Results: The upper limit of EVI1 transcript levels in 27 NBM samples was 8.0%. Receiver operating characteristic curve analysis showed that 1.0% (a 0.9-log reduction from the normal limit) was the EVI1 optimal diagnostic cutoff value for significantly differentiating relapse (P=0.049). A total of 23 patients (12%) had EVI1 levels ≥1.0%. EVI1≥1.0% had no impact on complete remission achievement. EVI1≥1.0% was significantly associated with lower 2-year relapse-free survival (RFS), disease-free survival (DFS) and overall survival (OS) rates in the entire cohort (P=0.0003, 0.0017 and 0.0009), patients with normal karyotypes (n=148, P=0.0032, 0.0047 and 0.0007) and FLT3-ITD (-) patients (n=150, all P<0.0001). Multivariate analysis showed that EVI1≥1.0% and FLT3-ITD (+) were independent adverse prognostic factors for RFS (Table 1), DFS and OS in the entire cohort. In addition, patients with EVI1 between 1.0% and 8.0% had 2-year RFS rates similar to those with EVI1≥8.0% (P=0.16), and both patient groups had significantly higher RFS rates than those with EVI1<1.0%.

Table 1.

	HR (95%CI)	P value
EVI1 expression		
≥1.0%	4.0 (2.1-7.7)	<0.0001
FLT3-ITD		
(+)	3.4 (1.9-6.0)	<0.0001
PLT count		
<100×10E9/L	2.1 (1.1-4.3)	0.030
Blast percentage in BM		
>65%	2.1 (1.1-3.6)	0.017

Summary/Conclusions: EVI1 transcript levels at diagnosis could further stratify adult ICR-AML, and high EVI1 expression predicts poor outcomes in patients receiving chemotherapy only. The optimal cutoff value which best differentiates patients is different from the normal upper limit.
Grant support: The Nature Science Foundation of China (81370637, 81370639 and 81570130).

PB1678

EFFICACY AND SAFETY OF DECITABINE IN ELDERLY AML PATIENTS: A REAL LIFE MULTICENTER EXPERIENCE OF THE NETWORK RETE EMATOLOGICA LOMBARDA

E. Borlenghi[1,*], C. Cattaneo[1], M. Bernardi[2], C. Basilico[3], N. Frachiolla[4], M. Fumagalli[5], M. Rossi[6], E. Sala[2], M. Sciumè[4], E. Todisco[6], M. Petullà[1], G. Rossi[1]
[1]Hematology, Spedali Civili, Brescia, [2]Hematology and BMT Unit, San Raffaele Scientific Institute, Milano, [3]Medicina Specialistica-Ematologia, ASST Sette Laghi, Varese, [4]Hematology and BMT Unit, IRCS Ca Granda Ospedale Maggiore Policlinico, Milano, [5]Hematology, ASST Monza - San Gerardo Hospital, Monza, [6]Hematology, Humanitas Cancer Center , Milano, Italy

Background: The optimal treatment decision in older patients (pts) with AML remains controversial, especially in patients pts with comorbidities, non-fit to intensive therapy or with AML adverse biologic features. Recently decitabine was approved in Italy in AML pts unfit to chemotherapy aged >65 years (y) and could be adopted in a population based setting.
Aims: To evaluate efficacy and toxicity of decitabine in a consecutive series of elderly AML pts (no M3), considered unfit to chemotherapy (CT) according to Ferrara et al (Leukemia, 2013) and treated at 6 centers of the Hematological Lombardy Network (REL).
Methods: Between Dec 2015 and Dec 2016, 46 (F/M: 22/24) newly diagnosed AML pts received decitabine (20mg/mq/daily for 5 days every 4 weeks) as outpatients. Median age was 76 y (69-85), ECOG performance status (PS) was ≥3 in 10.8%. According to "fitness", 41 pts (89.1%) were defined unfit to intensive CT, 1 frail and 4 fit. Unfitness causes were age >75y (58.5%), PS ECOG≥3 unrelated to leukemia (12.2%), and comorbidities (29.3%). AML was "de novo" in 25 pts (54.3%), therapy-related in 3 and secondary to antecedent hematological disorders in 18 pts. WBC count at diagnosis was 4.4 x10^3/mL (0.46 to 63), marrow blasts were 51% (<30% in 19.5% of pts). Karyotype (K) was normal (NK) in 43%, t(8;21) in 4.5%, intermediate in 20.5%, adverse (adv) in 32% of

pts, according to ELN (Doehner, 2017). In 2 pts it was not evaluable. Molecular analysis was available in 17/19 NK, NPM1 was mutated in 5 cases, with (2) or without (3) FLT3-ITD mutation.
Results: The total number of cycles administered was 231 (median 3.5; range 1-20). In 37/46 evaluable pts (2 ongoing, 1 early and 6 aplastic deaths), overall response rate (ORR) and complete remission (CR) rate were 51.% and 32%, respectively. Partial response and hematological improvement were achieved in 5.5% and in 13.6%, stable disease in 29.9% and failure in 19% of pts, respectively. Median time to best response was 3.5 months (range 1-8.5). Median response duration was 5.3 months (1-18+ ms). Relapse/disease progression was observed in 42% of responders. ORR was 21.4%, 47.3% and 77% in adv, NK and intermediate K, respectively (P=0.0289). After a median follow-up of 6.5 months, median survival was 8.4 months and projected OS at 1 y and 2 y was 43%+/-9 (SEM) and 30%+/-12% (SEM). Treatment was fairly well tolerated except for a high incidence of infections (46 episodes in 231 cycles) particularly during the first 3 cycles (29% *vs* 11%) (p 0.0072). Pneumonia was the most frequent infection (46%), followed by sepsis (28%). It was more frequent during the first 3 cycles [14% *vs* 4% : p 0.012)] when 44% of cases were of suspected fungal origin (3 probable aspergillosis and 4 possible IFI). Death occurred in 24 pts (52.2%): 12 (50%) of disease progression, 1 of early CNS hemorrhage and 11 (45.8%) of infection. In the first 3 months, infections were responsible for 46.7% of deaths. Pulmonary IFI were fatal in 57% of cases. These figures are higher than those reported by Cashen (JCO 2010) where the frequency of pneumonia was 11%.
Summary/Conclusions: These preliminary data confirm, in a population based setting, the high efficacy of decitabine and its longer time to response (more than 3 cycles) compared to CT. However infections complications were more frequent than expected and often fatal, particularly early during treatment. Since pneumonia, especially IFI, was the major cause of death, the adoption of routine antimicrobial prophylaxis may be considered in order to reduce early mortality and further improve the results.

PB1679

CLOFARABINE, CYTARABINE AND MITOXANTRONE FOR RELAPSED OR REFRACTORY ACUTE MYELOID LEUKAEMIA – INTERIM RESULTS OF A PROSPECTIVE PHASE 2 STUDY
H. Gill[1,*], H. W. Ip[2], S. F. Yip[3], B. Kho[4], H. Lee[5], V. Mak[5], J. Lau[6], C. K. Lau[7], S. Y. Lin[8], R. Wong[9], W. Li[10], Y. L. Kwong[1]
[1]Medicine, The University of Hong Kong, [2]Pathology, Queen Mary Hospital, [3]Medicine, Tuen Mun Hospital, [4]Medicine, Pamela Youde Nathersole Eastern Hospital, [5]Medicine, Princess Margaret Hospital, [6]Medicine, Queen Elizabeth Hospital, [7]Medicine, Tseung Kwan O Hospital, [8]Medicine, United Christian Hospital, [9]Medicine and Therapeutics, [10]Clinical Oncology, Prince of Wales Hospital, Hong Kong, Hong Kong

Background: In unselected patients with acute myeloid leukaemia (AML) in first relapse or refractory to primary daunorubicin / cytarabine therapy, complete response (CR) rate is merely 20 - 30%. In patients <60-years old, CR rates of about 55% may be achieved.
Aims: We tested in a multicenter prospective phase 2 study the efficacy and safety of clofarabine, cytarabine and mitoxantrone (CLAM) in AML patients in first relapse or refractory to first-line daunorubicin / cytarabine induction therapy.
Methods: Consenting patients aged 18 to 65 years in first relapse or refractory to first-line dose-intensified daunorubicin / cytarabine were recruited. Bone marrow pathology and karyotype at diagnosis and relapse were centrally reviewed. Next-generation sequencing of a myeloid panel of 67 genes was performed. Re-induction CLAM comprised clofarabine (40mg/m^2/day, days 1-5), cytarabine (750mg/m^2/day, days 1-5) and mitoxantrone (12mg/m^2/day, days 3-5). Bone marrow assessment was done on day 28 using standard criteria. Treatment toxicity was evaluated using the Eastern Cooperative Oncology Group Common Toxicity Criteria (ECOG-CTC). Survivals were determined using Kaplan Meier method. The primary outcome was the response on day 28. Secondary outcomes included treatment toxicity, leukaemia-free and overall survivals.
Results: In this interim analysis, 24 patients (14 men, 10 women) with a median age of 44.5 (19-66) years were treated. Karyotypic and genetic profiles were: normal karyotype (N=8) (*NPM1* mutant, N=1; *FLT3*-WT, N=8), t(8;21)(q22;22) (N=4) (*KIT D816V* mutant, N=1), inv(16)(p13.2;q22)/t(16;16)(p13.2;q22) (N=1) (*KIT D816V* mutant, N=1), inv(3)(q21;q26) (N=5), del (11)(q23) (N=2), t(9;11)(p21;q23) (N=1), trisomy 13 (N=1), near-tetraploidy (N=1), and complex karyotype (N=1). Twenty patients (83.3%) responded (CR, N=16; CR with incomplete hematopoietic recovery, N=4). Eight responding patients underwent allogeneic haematopoietic stem cell transplantation. Grade 3/4 haematologic toxicity was seen in all patients. Grade 1/2 and grade 3/4 hepatotoxicity was observed in 17 (70.8%) and 2 (8.3%) patients respectively. Grade 1/2 rash was observed in 4 patients (20%). Cardiotoxicity or treatment-related mortality was not seen. With a median of follow-up of 4 (1-32) months, 6 patients relapsed. The 12-month overall and leukaemia-free survivals were 81.7% and 66.8% respectively.
Summary/Conclusions: CLAM resulted in a high CR rate for AML in first relapse or refractory to first-line induction therapy, which was associated with an acceptable toxicity profile.

FATAL EVOLUTION IN THE FIRST 96 HOURS OF PATIENTS DIAGNOSED WITH ACUTE LEUKEMIA: ANALYSIS OF A SERIES OF 346 CONSECUTIVE CASES OF ACUTE LEUKEMIA IN A SINGLE CENTER
S. Martin-Batista[1,*], J. M. Raya[1], T. Martin-Santos[1], B. Soria[1], R. Arcas[1], M. Moreno[1], S. Lakhwani[1], B.-J. González-González[1], M.-T. Hernández-García[1]
[1]Hematology and Hemotherapy, Hospital Universitario de Canarias, La Laguna, Spain

Background: The very early death of a newly diagnosed acute leukemia (AL) patient is very frustrating, and there are very few published works (except for the case of acute promyelocitic leukemia, APL) analyzing this circumstance and the features of these patients.
Aims: Our objective was to study the main characteristics of patients with acute leukemia who died within the first 96 hours after diagnosis in our centre in the last 15 years.
Methods: We studied all cases of acute leukemia diagnosed in our institution between April 2002 and January 2017, focusing on the analysis of those who died within the first 96 hours after diagnosis. In this subset of patients, we collected data concerning clinical presentation, hemogram, biochemical parameters, coagulation status, performance of a bone marrow aspirate, acute leukemia subtype, started therapy, initiation or not of induction chemotherapy, time elapsed from diagnosis to death (hours), and cause of death, among others.
Results: A total of 346 consecutive cases of acute leukemia were recorded in this period of time: 222 of acute myeloid leukemia (AML, 64%) and 124 of acute lymphoblastic leukemia (ALL, 36%). Thirty-three patients were diagnosed of acute promyelocytic leukemia (15% of all AML). Those patients who died in the first four days after the diagnosis were only seven (2%), with a median of 45 hours of life (range 21-96). Main clinical and analytical findings are shown in the Table 1. They were 5 men and 2 women with a median of 57 years (range 22-91). Two of the seven patients had an APL (6% of all diagnosed APL). All patients showed leukocytosis, but hyperleukocytosis was only recorded in 2/7 patients, and severe thrombocytopenia (Plt ≤ 20 x10^9/L) in 3/7. There was possibility of bone marrow aspiration only in 4/7 cases. Coagulopathy was detected in four of six patients, including criteria for disseminated intravascular coagulation (DIC) in three cases. The exitus took place in the Intensive Care Unit in 5 cases, while it occurred in the Hematology facility in two.

Table 1.

Main features of the 7 patients who died in the first 4 days after diagnosis of AL.

	Case #1	Case #2	Case #3	Case #4	Case #5	Case #6	Case #7
Age (sex)	22 (M)	49 (F)	91 (F)	74 (M)	54 (M)	67 (M)	57 (M)

Hours from diagnosis	45	38	32	24	48	21	96

Abbreviations: PB, peripheral blood.

Summary/Conclusions: In our experience, about 2% of patients with acute leukemia die within the first 96 hours after diagnosis (including 6% of APL). Clinical and analytical feautures of this subset of patients are very heterogeneous, although AML clearly predominate on ALL. More extensive and multicenter studies are needed to deepen into the circumstances conditioning this early fatal course of the disease.

Background: Invasive fungal infections (IFI) are a major cause of mortality and morbidity in acute myeloid leukemia (AML) patients receiving remission induction therapy, and relapsed/refractory AML patients. Posaconazole prophylaxis has shown the greatest benefit in preventing IFI in AML .
Aims: We present the data of our real-life experience in AML patients under PP.
Methods: We have retrospectively reviewed the data from 82 AML patients

receiving 105 cycles of chemotherapy between June 2012 and December 2016 in Marmara University Pendik Research and Training Hospital. Median patient age was 50 years (18-73); and there was no significant gender difference (38 female *vs* 44 male (46% *vs* 54%)). All patients had active disease, 78 (74.3%) of them received 3+7 (idarubicine - ara-c), 25 (23.8%) of them FLAG-Ida, 1 patient received EMA and 1 patient received CLARA chemotherapy protocol. Acute promyelocytic leukemia was excluded from the analysis. All patients received posaconazole as oral suspension at the dose of 200 miligrams three times daily starting on the first day of chemotherapy. Prophylaxis was continued until marrow regeneration, or occurrence of IFI, or onset of adverse events, or discontinuation due to other reasons. All fungal infections were classified as possible, probable, or proven according to European Organization for the Research and Treatment of Cancer (EORTC) and the Mycoses Study Group (MSG) consensus criteria.

Results: Mean posaconazole prophylaxis duration was 20±13 (1-68) days. This duration was 29.7 days (16-50) in patients receiving prophylaxis until marrow recovery, 18.9 (9-34) days in patients developing IFI under prophylaxis, and 12.7 days (1-68) in prophylaxis discontinuations due to adverse events and other reasons. Posaconazole prophylaxis was administered until marrow recovery without IFI (clinical success rate) in 42 of 105 (40%) chemotherapy cycles. In 18 cycles prophylaxis was stopped after diagnosis of IFI (%17.1). Discontinuations were due to adverse events in 6 cycles (5.7%), and due to other reasons (diarrhea, intolerance of oral medication, recurrent high grade fever, death) in 39 cycles (37.1%). IFI incidence under effective posaconazole prophylaxis was 28.1% (18/64). Total clinical failure rate was 60% (63/105). IFI was diagnosed with pulmonary nodules in 12 of 18 patients (66.6%; EORTC-MSG: possible), with galactomannan positivity in 3 patients (16.6%; EORTC-MSG: probable), and with fungal culture in 3 patients (16.6%; EORTC-MSG: proven). Data from 70 patients were available for mortality analysis. In patients receiving effective posaconazole prophylaxis, all-cause mortality rate at day 100 was (9/44; 20.4%) significantly lower than patients unable to continue posaconazole prophylaxis (12/26; 46.1%) (p:0.023). In the subset of patients receiving prophylaxis as planned; there was no statistically significant difference in IFI incidence between previously untreated AML (13/46; 28.2%) and relapsed/refractory AML (5/18; 27.7%).

Summary/Conclusions: In our real-life experience, we have demonstrated early survival benefit in patients receiving effective posaconazole prophylaxis. Although our IFI rate was comparable to other real-life data, our clinical failure rate was slightly higher. This is probably due to compliance issues, since in many chemotherapy cycles (37.1%) posaconazole was discontinued due to "other reasons" such as drug intolerance. Although not as effective as in the clinical trials; our data still supports the use of posaconazole prophylaxis in high risk AML patients.

PB1682

CLINICAL AND PROGNOSTIC VALUE OF FLT3 MUTATIONS IN ACUTE MYELOID LEUKEMIA PATIENTS IN ROUTINE CLINICAL PRACTICE – SINGLE CENTER EXPERIENCE

A. Radzhabova[1,*], S. Voloshin[1], I. Martynkevich[1], V. Shuvaev[1], M. Ivanova[1], E. Motyko[1], N. Cybakova[1], L. Polushkina[1], D. Shikhbabaeva[1], N. Potikhonova[1], S. Tyranova[1], M. Zenina[1], S. Kudryashova[1], A. Chechetkin[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Detection of FLT3 gene mutations in acute myeloid leukemia (AML) now recognized as an unfavorable factor that affects the disease course, emerging the risk of relapses and overall survival (OS) shortening. Although about 30% of AML patients harbor one of the FLT3 gene lesion, at present there are no internationally standardized assays to quantify FLT3 mutation burden and no results of randomized clinical trials intended to individualize AML treatment based on FLT3 status. Some hematologists advocate to allo-SCT as consolidation in FLT3 ITD+ patients, but this way could be hard in frail and old patients and in countries with low access to transplant techniques. On the other hand, the development of target drug therapy – FLT3-kinase inhibitors gives us a new hope for improvement in the treatment results of such poor-prognosis subset of AML patients.

Aims: To assess the frequency of FLT3 gene mutations and its impact on clinical parameters and overall survival of the patients with acute myeloid leukemia (AML) in routine clinical practice.

Methods: We have analyzed FLT3 gene mutation frequencies, complete blood count (CBC) parameters, karyotype and survival outcomes per FLT3-mutation status in 199 patients with AML (83 male / 116 female). The median age at diagnosis was 52 years (20-86 years). To determine FLT3 gene mutations we used the method of polymerase chain reaction (PCR) with subsequent restriction. FLT3 gene mutations were classified as internal tandem duplication (FLT3-ITD) and point mutation in the "A-loop" (FLT3-TKD). Statistical analysis was included Kruskall-Wallis ANOVA and Kaplan-Meyer curves.

Results: We observed next FLT3 gene mutations rates: FLT3-ITD - 22.6% (45/199), FLT3-TKD 5.5% (11/199), FLT3-ITD and FLT3-TKD in combination 1.0% (2/199), other 70.8% (141/199) patients had no mutations (FLT3-). CBC data at the time of diagnosis were as follows (median (max-min)): · FLT3-ITD: Hb 9.7 (3.7-13.0) g/dl, WBC 40.3 (0.6-400.0) x 10^9/l, blasts 80% (21-100), platelets 60 (2-140) x 10^9/L; · FLT3-TKD: Hb 10.2 (5.8-12.8) g/dl, WBC 62.4 (1.7-362.0) x 10^9/l, blasts 68% (23-100), platelets 55 (12-115) x 10^9/L; · FLT3-ITD+TKD: Hb 5.8, 8.4 g/dl, WBC 37.0, 157.0 x 10^9/l, blasts 65%, 86%, platelets 38, 186 x 10^9/L; · FLT3-: Hb 9.0 (2.8-14.0) g/dl, WBC 12.9 (1.0-260.0) x 10^9/l, blasts 64% (20-103), platelets 63 (1-334) x 10^9/L; Significant differences across the groups were seen only in WBC and blasts. Chromosomal aberrations were revealed in 38% of FLT3-ITD, 64% of FLT3-TKD, none of FLT3-ITD+TKD and 51% of FLT3- patients. All patients received chemotherapy (7+3, 5+2, HAM). Transplantation of hematopoietic stem cells (SCT) was performed in 28 (allo/auto 17/11) (14%) patients: FLT3-ITD allo-3; FLT3-TKD allo-1, auto-1; FLT3- allo-13, auto-10. We found significant (p=0.00024) differences regarding to OS between FLT3-ITD, FLT3-TKD and FLT3- patients (Figure 1). Median survival times were: 5.1 months for FLT3-ITD, 7.1 months for FLT3-TKD and 13.0 months for FLT3- patients.

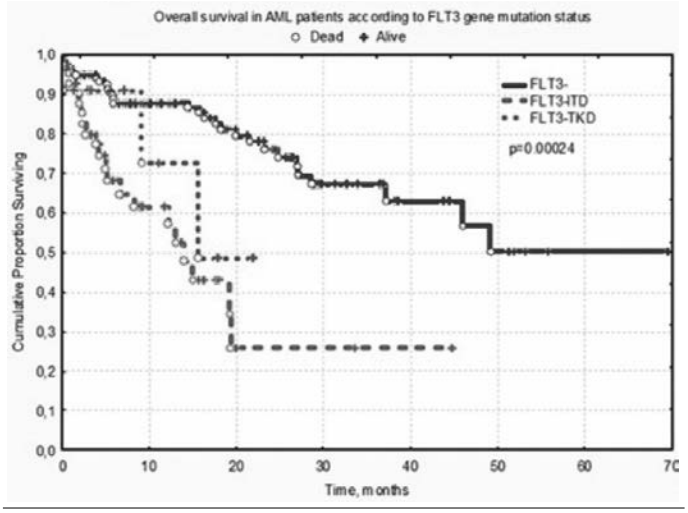

Figure 1.

Summary/Conclusions: We confirmed the role of FLT3 gene mutations as an unfavorable factor for AML patients in routine clinical practice by own experience. The investigation of qualitative assessment potential and target therapy value especially in SCT ineligible FLT3 gene mutations positive patients has of great value for AML management.

PB1683

TARGETING ENDOTHELIAL DYSFUNCTION FOR PROTECTION FROM ANTHRACYCLINE-INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE LEUKEMIA AND CO-MORBID ISCHEMIC HEART DISEASE

T. Lymanets[1,*], I. Skrypnyk[1], G. Maslova[1]
[1]Chair of Internal Medicine #1, Ukrainian Medical Stomatological Academy, Poltava, Ukraine

Background: Cardiotoxicity of chemotherapeutic drugs, in particular anthracycline antibiotics (AA), is one of the biggest problems in treatment of patients with acute leukemia (AL). Chemotherapy with AA is accompanied by systemic endothelial dysfunction, increasing the cardiovascular toxicity risk and promoting vascular complications. Patients with co-morbid ischemic heart disease (IHD) are at extremely high risk of myocardial injury and in need of anthracycline cardiotoxicity (AC) prevention.

Aims: To assess the effectiveness of L-arginine in the prevention of endothelial dysfunction as a predictor of acute AC in patients with AL and co-morbid ischemic heart disease.

Methods: A total of 66 patients with newly diagnosed acute leukemia (acute lymphoid leukemia – 7 patients, acute myeloid leukemia – 59 patients) and co-morbid ischemic heart disease were included in the study. The cohort consisted of 34 (51.5%) males and 32 (48.5%) females, age of 54–72 years, ECOG I-II. The duration of IHD ranged from 3 to 15 years. Chemotherapy (CT) schemes included AA (doxorubicin). The evaluation of endothelial dysfunction was performed by determining the stable metabolites of nitric oxide – nitrite anions $[NO_2]^-$ and activity of total NO-synthase in serum of patients before the CT and upon reaching a cumulative dose of AA from 100 to 200 mg/m^2 by doxorubicin. The mean total cumulative dose of AA reached 162,04±24,65 mg/m^{2}and 166,49±27,34 mg/m^{2}in groups I and II respectively. The study was approved by the local ethical committee and all patients gave a written consent before they were included in the study. Patients were divided into two groups: (n=36) – AL patients treated with CT; II (n=30) – AL patients, whom during the CT in order for prevention of acute AC were given L-arginine hydrochloride 4.2% 100 ml IV the day before and during administration of AA, followed by oral L-arginine aspartate for a month.

Results: In the debut of AL prior to the CT in all 66 (100%) patients the increased activity of total NOS in 3.8 times compared with the norm (p<0,001) was noted, with simultaneously reduced concentration of $[NO_2]^-$ in 1.5 times relatively normal values (p<0,05) (Table 1). As a result of two CT courses of remission induction in patients of group I the tendency to reduce the total NOS activity compared with its level before treatment was observed. At the same time the significant decrease of $[NO_2]^-$ in 1.8 times relatively normal values (p <0.01) and a trend to lower their content in 1.2 times compared with the data before treatment (p>0.05) was noted. These changes constitute the violation of NO-dependent vasodilation mechanism and endothelial dysfunction intensification. Provided achieving low cumulative dose of AA in patients of group II on the background of AC prevention with L-arginine showed a significant decrease in 1.9 times the total NOS activity (p <0.001) with a simultaneous tendency to increase concentration of $[NO_2]^-$ in 1.3 times (p>0.05) compared to that before treatment.

Table 1.

Indicators of total NOS and $[NO_2]^-$ in AL patients with co-morbid IHD in the CT dynamics.

Research groups		$[NO_2]^-$, μmol/L	NOS, μmol/L*min
Practically healthy (n=18)		3,2±0,38	0,61±0,08
pts of group I (n=36)	before CT	2,18±0,31*	2,3±0,14*
	after CT	1,8±0,21*	1,97±0,13*
pts of group II (n=30)	before CT	2,14±0,29*	2,1±0,14*
	after CT	2,4±0,33	1,2±0,11*√δ

Note: significant differences * – between indicators of healthy persons and in the groups (p<0.05); √ - between indicators before CT and upon reaching cumulative dose of AA 100-200 mg/m² (p<0.05), δ - between indicators of groups I and II in reaching cumulative dose of AA 100-200 mg/m² (p<0.05).

Summary/Conclusions: Thus, during the CT with the inclusion of AA without L-arginine in patients with AL and co-morbid IHD we observed the depletion of NO substrate production, accompanied by endothelial dysfunction impairment. The additional appointment of L-arginine on the background of CT can restore synthesis of NO and, respectively, the mechanism of NO-dependent vasodilation, thus reducing the risk of early anthracycline cardiotoxicity development.

PB1684

CLINICAL CHARACTERISTICS AND SURVIVAL OUTCOMES IN ACUTE ERYTHROID LEUKEMIA (AML-M6): AML/MDS WORKING PARTY STUDY OF KOREAN SOCIETY OF HEMATOLOGY

J.J. Han[1,*], H.-J. Kim[2], W.-S. Min[2], I. Kim[3], Y. Koh[3], H.-J. Kim[4], J.-S. Ahn[4], Y. Park[5], B.S. Kim[5], H.-J. Shin[6], C.W. Jung[7], J.-W. Cheong[8], J.-H. Lee[9], J. Park[10], W.S. Lee[11], H.-J. Yoon[12]

[1]Internal Medicine, Kyung-Hee University Medical Center, [2]Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, [3]Internal Medicine, Seoul National University College of Medicine, Seoul, [4]Internal Medicine, Chonnam National University Hwasun Hospital, Hwasun, [5]Internal Medicine, Korea University School of Medicine, Anam Hospital, Seoul, [6]Internal Medicine, Pusan National University Hospital, Busan, [7]Internal Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, [8]Internal Medicine, Yonsei University College of Medicine, [9]Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, [10]Internal Medicine, Gachon University Gil Medical Center, Incheon, [11]Internal Medicine, Inje University Busan Paik Hospital, Busan, [12]Internal Medicine, Kyung Hee University School of Medicine, Seoul, Korea, Republic Of

Background: Acute erythroid leukemia is a morphologically distinct and rare entity designated as M6 in FAB classification. In Korea, patients with AML-M6 have been treated as acute myeloid leukemia with intensive chemotherapy whenever possible rather than as myelodysplastic syndrome. The 2016 revision of the WHO reclassified erythroid/myeloid subtype (a case with ≥50% BM erythroid precursors and ≥20% myeloblasts among non-erythroid cells) to MDS category based on the close biological and genetic relationships between them.
Aims: The aims of this multi-center study were to characterize clinical characteristics and treatment outcomes in patients with newly diagnosed acute erythroid leukemia.
Methods: Clinical data from newly diagnosed M6-AML patients between 2002 and 2012 at 11 academic centers were retrieved from the electronic registry data of AML/MDS working party of Korean Society of Hematology. Conventional cytogenetic analysis was performed on metaphase cells prepared from bone marrow aspirate by G-banding technique. Patients were classified according to the UK MRC cytogenetic risk criteria and the International Prognostic Scoring System (IPSS) risk groups for MDS based on karyotypes. Survival curves were analyzed using the Kaplan-Meier method and compared with a log-rank test. A p-value <0.05 was considered statistically significant.
Results: A total of 84 patients with AEL (M6-AML) as defined by 2008 WHO classification criteria were included in this study. The median age at diagnosis was 55 years with following distribution: age ≤ 49, 34 patients (40.5%); age 50 – 59, 17 (20.2%) patients; 60 – 69, 19 (22.6%) patients; age ≥70, 14 (16.7%) patients. There were 50 (59.5%) males and 34 (40.5%) females. Median hemoglobin, white blood cell count, and platelet count were 8 g/dL, 3.69 × 10^9/L, and 58 × 10^9/L, respectively. Peripheral blood blasts were observed in 55 (65.5%) patients. Cytogenetic results were available in 80 patients. Among them, karyotype was normal in 43 (53.8%) and complex in 13 (15.5%) patients, respectively. Trisomy 8 was observed in ten (12.5%) patients. Monosomies of chromosome 5 and 7 were observed in five (6.2%) and four (5.0%) patients, respectively. Four (5.0%) patients had t(9;22)(q34;q11.2). Cytogenetic risk groups according to UKMRC criteria were intermediate in 63 (78.8%) patients, and poor in 17 (21.2%) patients. Seventy-two (85.7%) patients received induction chemotherapy and 55 patients (76.4%) achieved complete remission. Nineteen patients received two or three cycles of induction chemotherapy. Thirty-eight patients (45.2%) underwent allogeneic hematopoietic stem cell transplantation (HSCT): 8 patients, matched-sibling donor; 15 patients, matched-unrelated donor; 5 patients, alternative donor were used. Treatment-related mortality of HSCT was observed in five (17.9%) patients. Fourteen (16.7%) among the study patients relapsed. The median overall survival (OS) of total 84 study patients was 21 months. Patients with intermediate risk karyotype showed better median OS than those with poor risk karyotype (22 months *vs* 7 months, P=0.020). The median OS was similar in patients with good and intermediate IPSS, but significantly worse in patients with poor IPSS (21 months, 27 months, 7 months, respectively, P=0.026) (Figure 1).

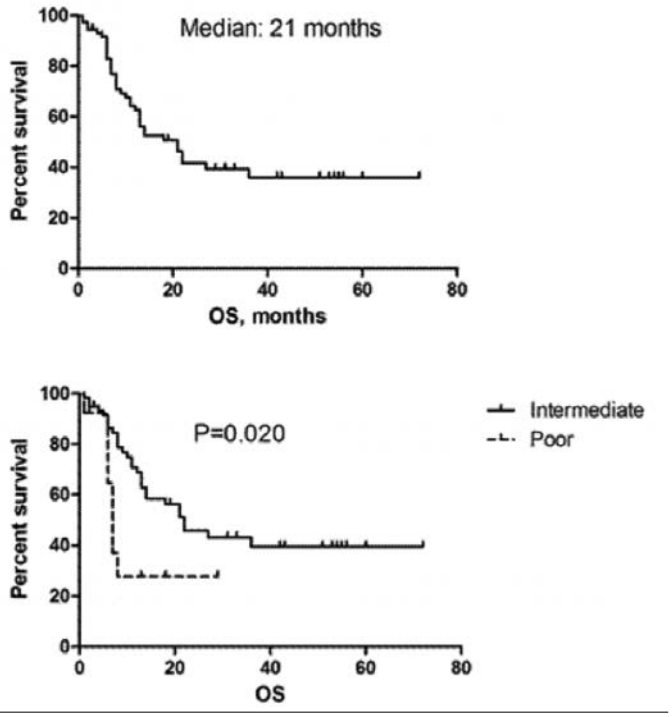

Figure 1.

Summary/Conclusions: Patients in this study were younger than previous studies. The most common aberrations in chromosomes are trisomy 8, followed by numerical changes in chromosome 5 and 7. The median in total patients was 21 months with many patients received intensive treatment, including HSCT in 45.2% of patients. We also confirmed that patients with poor-risk karyotypes had very poor median OS of 7 months. Therefore, we suggest that although erythroid/myeloid subtype is similar to the MDS with excess blast, treatment decision might be carefully considered according to the karyotype risk.

PB1685

PREGNANCY ACCUMULATES UNFAVORABLE MOLECULAR GENETIC AML AND SHOULD BE CONSIDERED AS A POOR PROGNOSTIC FACTOR

V. Troitskaya[1,*], E. Parovichnikova[1], A. Sokolov[1], A. Kokhno[1], Z. Fidarova[1], A. Sidorova[1], O. Gavrilina[1], G. Galstian[1], A. Bazhenov[1], L. Kuzmina[1], M. Drokov[1], S. Makhinya[1], O. Latishkevich[2], A. Zvereva[2], A. Olenev[3], O. Korobitsyna[4], A. Korobkin[4], V. Savchenko[1]

[1]National Research Center for Hematology, [2]Centre of Family Planning and Reproduction, [3]City Clinical Hospital №24, Moscow, [4]Chelyabinsk regional hospital, Chelyabinsk, Russian Federation

Background: Acute myeloid leukemia (AML) during pregnancy – is a rare clin-

ical condition that limits the possibility to conduct large prospective clinical studies. All publications present small retrospective data and case reports. Most of them conclude that pregnancy doesn't affect the prognosis of acute leukemia.
Aims: To assess the pregnancy, as independent prognostic factor, in non APL AML-patients (pts), prospectively treated within Russian AML multicenter studies.
Methods: From 1990 to 2017 yy the Russian Acute Leukemia study group has treated 33 with *de novo* AML pregnant women (Me-27 (21-42) yrs). AML was diagnosed in the Ist trimester in 1 woman (3%), in the IInd– 15 (45,5%), in the IIIrd- 17 (51,5%). Molecular genetic risk group was estimated in 27/33 pts: 52% (n=14) were referred to the intermediate risk group and 48% (n=13) to the poor prognosis. High risk group comprised complex karyotype (n=5), -7/del7 (n=4), translocations involving gene MLL (n=2), 1 pt - inv3/-7 and 1 pt - AML with myelodysplasia-related changes, normal karyotype and FLT-3+.
In 1 pt at the 1st trimester medical abortion was conducted and 11 women delivered at the gestation age of 34-40 weeks before chemotherapy (CT). 21 pregnant women received CT, that was started at 23 (14-32nd) weeks of gestation. Classical 7+3 was applied in all of pts: either with daunorubicin (45-60 mg/m^2), or mitoxantrone (10 mg/m^2), or idarubicin (12 mg/m^2) regarding the treatment study-protocol.
Results: As our data show, AML in pregnancy is characterized by high prevalence of unfavorable cytogenetic abnormalities (48%), that is substantially different from AML in non-pregnant women of the same age (11,5%) (p=0,006) [Blood 2016,128;22,p.5171]. 1 pt died before CT due to septic shock, 2 pts – in induction CT now. 2 pregnant women died due to severe infections in aplasia during induction (5,7%). So, induction results were evaluated in 30/33 pts: CR rate - 73,3% (22/30): after the 1st course CT - in 16 and after the 2nd– in 6 pts. In pts, with available cytogenetic data, CR was received in 100% (9/9) from the intermediate and in 80,0% (8/10) from the poor prognostic group. Primary resistance was registered in 6/30 pts (20%). Antenatal fetal mortality was registered in 2 cases at the 21stand 32nd weeks during induction. 29 children were born. Allogenic bone marrow transplantation (allo-BMT) was done in 10 of 28 (35,7%) AML-pts who had survived induction therapy at a median of 6 months after CR. 4 pts relapsed after allo-BMT and 1 woman remained with refractory AML after allo-BMT. Our results demonstrated rather low 10-y OS and DFS (10,48% and 10,46%) in women, whom AML was diagnosed during pregnancy. In order to evaluated the role of allo-BMT, we performed a landmark analysis (landmark=6 months of CR), that has shown better OS and DFS only in pts after allo-BMT (Pic) (Figure 1).

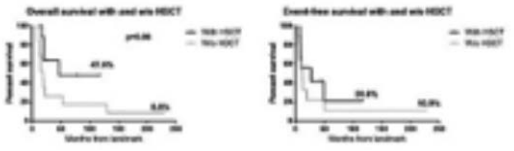

Figure 1.

Summary/Conclusions: Our results demonstrate: almost half of women, who were AML diagnosed during pregnancy, are referred to the poor molecular genetic prognostic group; they demonstrated very low OS and DFS whit their improvement after allo-BMT.

PB1686

CLOFARABINE IN RELAPSED-REFRACTORY ACUTE MYELOGENOUS LEUKEMIA: A SINGLE CENTRE EXPERIENCE

B. Scappini[1,2,*], G. Gianfaldoni[1], M. Armenio[2], F. Mannelli[1], I. Cutini[1], M. Piccini[2], C. Biagiotti[2], R. Fanci[2], M. Di Gioia[2], A. Bosi[2]
[1]Haematology, AOU Careggi Florence, [2]Haematology, University of Florence, Florence, Italy

Background: Clofarabine has been shown to be effective in AML patients, mainly in combination with high dose cytarabine
Aims: On the basis of these reports, we tested clofarabine in association with high dose cytarabine in relapsed/refractory AML patients, selecting cases of primary refractory to at least two induction therapies, relapsed but refractory to a standard re-induction treatment, or very early relapsed.
Methods: Betweeen 2008 and 2016 we treated 67 patients with a regimen including clofarabine at 22,5 mg/m^2 daily on days 1-5, followed after three hours by cytarabine at 1 gr/m^2 daily on days 1-5.
Among the 67 patients, 24 were in first relapse, 29 in second or third relapse, 14 with resistant disease. The mean age was 54 years (range .36-77 years).
Results: 20/67 patients achieved a complete remission (29,9%), 4/67 a partial response (6%) ,38/67 had resistant disease (56,7%), 3/67 died of complications during the aplastic phase (4,4%). The most frequent non haematologic adverse events were: transient liver toxicity (41% grade 1-2, 11% grade 3-4) skin rash (33%), vomiting (28%), diarrhea (15%). Comparing with other salvage strategies, in this cohort of patients we did not observe a significant delay in bone marrow recovery (median time to ANC recovery 21 days). Febrile neutropenia was observed in 58 cases (85%), with bacterial infections microbiologically documented in 20 patients (29%) and 2 cases (3%) of fungal infections. The median overall survival of the whole cohort was 115 days , with a median event free survival of 111 days. Among the responding patients, 16 (24%). underwent allogeneic bone marrow transplantation; in these selected patients, median overall survival was 185 days.
Summary/Conclusions: These results suggest that the clofarabine-ARA-C regimen was able to induce a response in about one third of this particularly poor prognosis category of patients, with safety data consistent with previously reported salvage therapies. Nevertheless, long term results remain still and completely unsatisfactory. Further studies, with different combinations or in more selecting conditions, are warranted.

PB1687

PRESENCE OF MULTIPLE DRIVERS IN THE SELECTION OF HIGH AND LOW INTENSITY CHEMOTHERAPY IN AML

B. Pandya[1,*], A. Hadfield[2], B. C. Medeiros[3], S. Wilson[1], E. Berrak[1], T. Bailey[2], S. Flanders[1], A. Rider[2], L. Horvath[1]
[1]Astellas Pharma Inc., Northbrook, United States, [2]Adelphi Real World, Cheshire, United Kingdom, [3]Stanford University, Stanford, United States

Background: Data on the key drivers of initial treatment choice for patients diagnosed with acute myeloid leukemia (AML) in the United States is limited. The use of age as a selection driver of induction therapy is well established; however, there is limited data and a knowledge gap about additional factors driving treatment selection.
Aims: This analysis explored the key physician drivers, which led to the selection of high- and low-intensity induction therapy in AML patients.
Methods: Data from the Adelphi AML Disease Specific Programme, a real-world, cross-sectional survey conducted between February–May 2015, was analyzed. A total of 61 hematologists/oncologists provided attitudinal information about their management and treatment choices for AML patients via survey. Each physician was provided a pre-specified list of 16 patient characteristics. Via two separate questions, they were asked to select those considered important when choosing high and low intensity chemotherapy for their AML patients. Characteristics were analysed descriptively and ranked based on the frequency of mention from highest to lowest.
Results: The top three drivers for decision making when selecting high and low intensity treatment were: patient age, performance status and presence of comorbidities. More than 60% of physicians would prescribe high-intensity treatment to patients aged under 65, with a good performance status or with no comorbid conditions. Over half of physicians would consider those who are eligible for a stem cell transplant or have a mutation in the CEBPA gene to be eligible for high-intensity chemotherapy (Table 1). Low-intensity chemotherapy was considered by more than 60% of physicians as being the most appropriate treatment for patients aged ≥65, with a poor performance status or increased number of comorbid conditions. A total of 38% of physicians would likely consider low-intensity chemotherapy if the patient was ineligible for a stem cell transplant or had had previous cancers or exposure to radiation/chemotherapy in the past.

Table 1. Top 5 patient characteristics considered by physicians when choosing high- or low-intensity treatment in AML.

Top 5 drivers of selection	Total Physicians (N=61)
High-intensity chemotherapy	
Patients aged <65 years	41 (67%)
Good performance status (ECOG score 0-1)	39 (64%)
Patients without comorbidities	37 (61%)
Patients eligible for stem cell transplant	33 (54%)
Patients with mutation in the CEBPA gene	33 (54%)
Low-intensity chemotherapy	
Patients aged ≥65 years	41 (67%)
Very poor / poor performance status (ECOG score 2+)	38 (62%)
Patients with comorbidities	38 (62%)
Patients ineligible for stem cell transplant	23 (38%)
Patients with prior cancers / previous to radiation therapy or chemotherapy	23 (38%)

Summary/Conclusions: Irrespective of treatment intensity, patient age, performance status and the presence of comorbidities are the top three drivers of treatment selection for physicians. In addition to patient age, identification of the other key drivers for therapy selection and the physician awareness of them is critical to ensure patients receive the most appropriate therapy. This improved awareness could also lead to better communication tools for patients and improve shared decision-making.

PB1688

IRAIN LONG NON CODING RNA ARE DOWN-REGULATED IN POOR PROGNOSIS AML PATIENTS

M. Eizadifard[1], M. Yaghmaie[1,*], H. Pashaiefar[1], E. Gheisari[1], M. Montazeri[1], K. Alimoghaddam[1], A. Ghavamzadeh[1]
[1]Hematology, Oncology and Stem cell Transplantation Research Center, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic Of

Background: *IRAIN* which is produced from the insulin-like growth factor type I receptor (IGF1R) imprinted locus is a newly identified lncRNA. There are very little knowledge about the specific role of this lncRNA in tumorogenesis presses. Recent studies were revealed that *IRAIN* is down-regulated in leukemia cell lines and viral expression of the *IRAIN* lncNRA inhibits tumor cell migration, suggesting a tumor suppressor function for this transcript.
Aims: In this study, we attempted to examine the expression level of *IRAIN* in different cytogenetic subtypes of AML patients.
Methods: Using quantitative polymerase chain reaction (qPCR) the expression level of *IRAIN* were analyzed in bone marrow specimen of AML patients (n=76) and healthy individuals (n=18).
Results: IRAIN expression was found to be remarkably decreased in AML patients compared with healthy individuals (p= 0.02). Significant IRAIN down-regulation was observed in all FAB types except for the M3 (p= 0.11). When we analyzed the expression level of *IRAIN in* different cytogenetic subtypes of AML patients the statistically down-regulation of IRAIN was observed only in poor prognosis AML patients (p= 0.008).
Summary/Conclusions: Our results suggest that down-regulation of IRAIN lncNRA might play a role in the AML development and hence may be a potential prognostic factor and serve as therapeutic target for AML treatment.

PB1689

PERFORMANCE OF THE LEUKOSTRAT® CDX FLT3 MUTATION SIGNAL RATIO ASSAY TO DETECT INTERNAL TANDEM DUPLICATION AND TYROSINE KINASE DOMAIN MUTATIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

A. Osgood[1,*], E. Shakeri[2], V. Atkinson[1], N. Kha[3], C. Simon[4], J. Thornes[3,4,5], T. Stenzel[1], J. Miller[1]
[1]Invivoscribe Technologies, San Diego, United States, [2]Product Development, Invivoscribe Technologies, [3]Laboratory for Personalized Molecular Medicine (LabPMM), San Diego, United States, [4]Laboratory for Personalized Molecular Medicine (LabPMM), Kawasaki, Japan, [5]Laboratory for Personalized Molecular Medicine (LabPMM), Martinsried, Germany

Background: Acute myeloid leukemia (AML) in general has a poor prognosis. Assessment of the mutation status of the *FLT3* (fms related tyrosine kinase 3) receptor gene in AML is the most important prognostic indicator of disease outcome, which is often substantial, as many studies in AML have shown that the presence of *FLT3* activating mutations portends a poor prognosis. The LeukoStrat® CDx *FLT3* Mutation Assay targets regions of the *FLT3* gene to identify internal tandem duplication (ITD) mutations and tyrosine kinase domain (TKD) mutations. Since this assay is a signal ratio (SR) assay with a validated cutoff of 0.05, demonstration of international harmonization of results is paramount. *FLT3* ITD mutations are caused by duplication and insertion of a portion of the *FLT3* gene that includes the region in and around the juxtamembrane region of the *FLT3* gene. These mutations vary in both the location and the length of the inserted duplicated DNA sequence. ITD mutations result in constitutive autophosphorylation and activation of *FLT3. FLT3* TKD mutations are caused by nucleic acid substitutions and/or deletions that result in a change in the amino acid sequence in this highly-conserved catalytic center. TKD mutations, such as D835 and I836 substitutions and deletions, result in constitutive autophosphorylation and activation of *FLT3.*
Aims: To assess the performance of the Invivoscribe® LeukoStrat® CDx *FLT3* Mutation Assay.
Methods: White blood cells were removed from peripheral blood after 30 minutes of centrifugation at 2000 xg to create leukocyte depleted blood (LDB). Various ratios of four ITD positive cell lines, with insert sizes from 21 bp to 279 bp, and one TKD positive cell line, with a D835 substitution mutation, were created over a wide range of signal ratios (0.02 to 1.83) and added to the LDB. Mononuclear cells were isolated from the contrived LDB samples. DNA was extracted and amplified via PCR. The amplicons were analyzed via capillary electrophoresis. The assay measured the ratio of signals from mutation against a background of signal from wild type. A *FLT3* mutation was detected (and reported as positive) if the mutant:WT type SR met or exceeded the clinical cut-off of 0.05. Proprietary software calculated the SR and reported positive or negative. Clinical specimens were de-identified by LabPMM in San Diego. DNA from twenty specimens was tested by three laboratories: LabPMM LLC in San Diego, LabPMM GmbH in Germany and LabPMM Gk in Japan.
Results: The analytical performance of the LeukoStrat® CDx *FLT3* Mutation Assay was evaluated using contrived LDB samples, with known *FLT3* mutations. For limit of blank (LoB), the SR was 0.00 in the ITD assay and 0.00 to 0.01 in the TKD assay, which is well below the clinical cutoff SR of 0.05. The limit of detection in the ITD assay detected allelic ratios of 0.03, 0.05, and 0.33 above the LoB SR in more than 95% of samples for insertions sized at 30 bp, 126 bp and 279 bp, respectively. The limit of detection in the TKD assay detected an allelic ratio of 0.05 above the LoB. For precision and reproducibility, the SR%CV was within 3-14% across ITD and TKD mutation types regardless of reagent lots, equipment, or operator.
There was 100% agreement between all three clinical LabPMM laboratory sites.
Summary/Conclusions: This robust assay produced a SR%CV less than 15% regardless of reagent lot, equipment or operator. The high reproducibility between the three laboratories on three different continents provides evidence that the Invivoscribe® LeukoStrat® CDx *FLT3* Mutation Assay is an internationally standardized assay.

PB1690

CLINICAL FEATURES AND OUTCOME OF PATIENTS WITH CORE BINDING FACTOR ACUTE MYELOID LEUKEMIA

S. Taoussi[1,*], N. Rekab[1], F. Lamraoui[1], S. Oukid[1], K.-M. Benlabiod[1], H. Brahimi[1], M.T. Abad[1]
[1]Hematoloy, EHS ELCC CAC, Blida, Algeria

Background: Acute Myeloid leukemia is classified into different prognostic groups according to their cytogenetic profil; AML with t (8; 21) or inv16/ t (16; 16) called AML CBF belong to a prognostic group of low-risk; they represent 15% to 20% of the AML.
Aims: The aim of this study is to present clinical , cytogentic features and outcome of this group of patients (pts) in an emerging country.
Methods: Cytologic diagnosis of AML CBF is completed by immunophenotyping and cytogenetic analysis:
t(8; 21), inversion 16/t (16.16) and del 16q22. Induction treatment: Daunorubicin 45 to 90 mg/m² day (d1-d3)+Cytarabine 100 mg/m² (d1- d7) (with progressive doses if major leukocytosis). Assessment between d 21 and d 28 by bone marrow analysis ; If failure a second course induction is performed by Cytarabine high dose 3 g m²/12 h d1, d3, d5. Central nervous system prophylaxis for patients (pts) with AML4, M5 and hyperleukocytosis forms. Consolidation: Cytarabine high dose: 2 to 3 cures; low dose of chemotherapy for pts older than 55 years or pts presented severe toxicity at the first induction. Research of Kit, FLT3 and residual disease is not available in our laboratory, hematological stem cell transplantation (HSCT) was proposed for all pts; if no compatible donor, 3 courses of Cytarabine high doses was instituted.
Results: From 2010 to 2016, cytogenetic analysis was performed in all cases of AML of which 58 cases (18,6%) of LAM - CBF were diagnosed. The male to female ratio was 0.5 ; average age: 37 years (16-72); t (8,21) was found in 28 pts (16 M,12F); inversion (16)(p13.11;q22.1), t(16,16)(p13.11;q22.1) and del 16q22 were found in 30 pts (12M,18F), respectively in 27 pts, 2 pts and 1 pt. Four cases of del(16)(p13) were associated with inv(16). For inv(16), FAB subtypes were AML4 (26), AML2 (1) and 3 AML; For t(8;21), there was 26 AML2 and 2 AML4. Evaluation of induction: not evaluable: 13 cases, Complete Remission (CR): 38 cases (65,5%); for 7 cases in failure , a second induction was proposed, we obtained 2 CR. 15 pts were transplanted. Outcome: 27 pts are alive in CR of which 12 transplanted . 31 pts died of which 18 toxic deaths (15 after induction treatment and 3 after engraftment). Median overal survival for inv(16) : 11 months *vs* 15 months for t(8;21) (p=0,87).
Summary/Conclusions: In our study, the frequency of the CBF AML is closer than those described in another Algerian study and literature: 18,6% *vs* 15.4% and 20% respectively; a slight predominance of the inv 16 or t (16; 16) identical to that reported by the SWOG study. The RC rate is under to that reported by the CALGB study. We noted less relapse compared with literature. Relapses were observed in pts with poor prognostic factors: age, leukocytosis and failure to first induction. Regarding the favorable prognosis of AML CBF, our results are bad because the high rate of toxic deaths. The CBF AML are characterized by a better prognosis, but with a 30% relapse rate essentially when associate poor prognosis factors such as a kit mutation that increases the risk to 70%, mutation FLT3, advanced age, the leukocytosis, severe thrombocytopenia and additional cytogenetic abnormalities.

PB1691

FLOW CYTOMETRY ANALYSIS SOFTWARE FOR REMOTELY LOCATED HAEMATOLOGISTS

M. Kelly[1,*]
[1]Haematology Department, Our Lady's Childrens Hospital Crumlin, Dublin, Ireland

Background: Current flow cytometry software packages are unsuitable in cases where the interpreter of the data isn't physically located at the computer with the software installed. This is particularly disadvantageous in urgent situations, such as in the diagnosis of acute leukemia.
Aims: Develop a tool to allow haematologists to analyse flow cytometry data from anywhere on any internet-enabled device *e.g.* tablet, smartphone, laptop, PC.
Methods: We came up with principles a new software package should adhere to: 1. should be accessible from any Internet-enabled device *e.g.* iPad, Android phone, Blackberry, laptop; 2. should not require installation; 3. FCS data should be anonymised; 4. data transfer should be secure and encrypted; 5. software must include all basic functionality of flow cytometry software *e.g.* dot plot graphs, histogram graphs and gating 6. should put collaboration to the forefront *e.g.* analysis can be instantly linked to via a web URL.
Results: The resulting software package is a web app which is accessible from any Internet-enabled device *e.g.* smartphone, tablet, laptop or PC. On mobile devices such as an iPad, touch is used for drawing of gates, selection of quadrants, selections of parameters etc. On laptop's and PCs, these are drawn via

the mouse or keypad. The software utilises the latest strides made in web technologies to respond to the varying screen sizes of devices, and display suitably sized graphs and gating information accordingly. Collaboration between parties is facilitated - a lab technician running the sample can upload the sample and instantly shared with other parties with the required permissions. Analysis, such as gating, can take place immediately and can then be instantly shared via a web URL. No sensitive file data is displayed within the platform. All data transfer happens via SSL encryption.
Web app is available at https://www.redmatterapp.com

Figure 1.

Summary/Conclusions: The latest web technologies can be effectively harnessed to enhance flow cytometry analysis and allow for faster, more accessible and more collaborative analysis. Within the field of haematology in particular, this opens up the option of remote diagnosis - a haematologist need to be in the lab, or even in the same country, to deliver a diagnosis.

PB1692

FLAG-IDA IN THE TREATMENT OF ACUTE LEUKEMIA: SINGLE-CENTER EXPERIENCE

M.I. Goyanes Martin[1,*], M.A. Canales Albendea[1], M. Fabra Urdiola[1], M.D.M. Meijon Ortigueira[1], V. Jimenez Yuste[1]
[1]Hematology, Hospital La Paz, Madrid, Spain

Background: A variety of different treatment regimens have been studied in an effort to improve outcomes of patients with relapsed or refractory acute myeloid leukemia (RR-AML), there appears to be no single superior approach. Spanish groups usually use the FLAG-IDA protocol (Fludarabine 30 mg/m2 days 1-4, Idarubicine 12 mg/m2 days 1-3, ara-C 2 mg/m2 days 1-5) in these patients.
Aims: To evaluate our response rates and the survival with FLAG-IDA protocol.
Methods: Descriptive study of a case series of patients with acute leukemia who received intensive induction chemotherapy with FLAG-IDA protocol at our hospital between January 2007 and December 2016. Biodemographic, histopathological, cytogenetic and molecular results and previous treatment were recorded. We analyzed the response rate, the 30-day mortality rate and the overall survival.

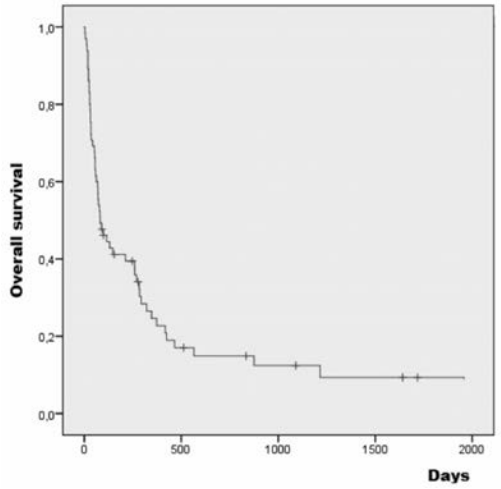

Figure 1.

Results: 65 patients received treatment with FLAG-IDA protocol between 2007-2016, 36 of them female, with and average age of 53.4 years (DS+/-23.3). We treated with this protocol mostly patients with relapsed or refractory acute myeloid leukemia (RR-AML) (primary refractory or resistant AML as defined by not achieving complete remission after 1 cycle of intense induction therapy); 60% (n=38) of patients had a RR-AML, 37% (n=23) of them were relapsed AML and 23% (n=15) refractory AML. Based on European Prognostic Index Score (EPI-SCORE) for patients with RR-AML, 61% of them had a poor prognosis (10-14 points), 36% had an intermediate prognosis (7-9 points) and only 3% had a favorable prognosis (1-6 points). The next important group, 25% (n=17) were MDS patients transformed to AML. We had 9% (n=6) patients with treatment related AML and 6% with other acute leukemia (3 cases of refractory ALL and 1 case of biphenotypic leukemia). We observed a global response rate of 63%: 51% (n=33) of patients had a complete response (CR) and 12% (n=8) partial response, 17% (n=11) did not have a response and 20% of patients were not evaluated after to receive the treatment because they had a early dead. The 30-days mortality rate was 21.5% (n=14), similar to the rate of no evaluated patients. We can see in the overall survival curve (picture 1) that most patients died first months after treatment, after that patients remain alive and we achieve a plateau. The median overall survival was 82 days (standard deviation: 25 days). 10 patients were alive when we analyzed the data (Figure 1).
Summary/Conclusions: Most AML patients ultimately die from their disease. In our case serie none died by any other cause. We had a similar response rate, mortality and overall survival that other groups in our country. Despite a variety of salvage therapy options, like FLAG-IDA protocol, prognosis in patients with RR-AML is generally poor and treatment is very complex.

PB1693

BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASMS - UNUSUAL PRESENTATIONS AND UNFAVOURABLE OUTCOMES

M. Guenova[1,*], A. Michova[1], T. Dikov[1], Y. Georgieva[1], B. Spassov[1], K. Prisadashka[2], M. Balabanova[2], V. Kaleva[3], G. Balatzenko[1]
[1]National Specialised Hospital for Active Treatment of Hematological Diseases, [2]Alexandrovska University Hospital, Sofia, [3]University Hospital St.Marina, Varna, Bulgaria

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy with an aggressive clinical course. Most patients (pts) with BPDCN have skin lesions and involvement of the peripheral blood, bone marrow, and lymph nodes. Very few cases have been described with lack of skin and or bone marrow manifestations at the time of diagnosis.
Aims: To characterise the clinical presentation and clinical outcomes of a cohort of consecutive patients with a rare blastic plasmacytoid dendritic cell neoplasm in a single institution.
Methods: Patients diagnosed with BPDCN at the National Hematology Hospital between 2010 and 2016 were retrieved from the database. The diagnosis was confirmed by morphology and immunophenotying by flow cytometry and/or immunohistochemistry, according to 2008 WHO Classification of Hematopoietic Neoplasms. The relevant clinicopathologic features were reviewed.
Results: We identified 8 adult patients at a median age of 70 years (range: 37-84 years) with a male:female ratio of 6:2 (75%:25%) and only 1 child. Mean values of blood cell counts were as follows: WBC 5.10^9/L; hemoglobin 99 g/L; platelets 116.10^9/L. LDH was generally elevated with a mean of 962.8 U/L. At diagnosis the skin was invoved in 5/9 patients. Five patients developed leukemic presentation with 40-95% of bone marrow infiltration. Interestingly, in 4 pts (50% of adult pts) the initial presentation affected other tissues and organs such as testis, bronchial wall, stomach and periorbital soft tissues, however, only the latter one case presented with a leukemic picture. Biopsies revealed diffuse, monomorphous infiltrate of medium-sized blast cells with irregular nuclei, fine chromatin with ≥1 nucleoli, scant and agranular cytoplasm, without angioinvasion or coagulation necrosis. Immunophenotype generally demonstrated CD45+, CD4+, CD56+, CD123+. No standard therapies were applied. Patients received CHOP or HyperCVAD or AML-induction therapy. However, response rates in adult patients were low and the mean OS was 2.6 months (ranging from early deaths before any treatment could be initiated to 10 months).
Summary/Conclusions: BPDCN is a rare aggressive disease that typically affects elderly patients. The most commonly affected non-hematopoietic organ is the skin, however any other organ or tissues can also be involved. Response to therapy if any is relatively short and long-term prognosis is poor despite of the site of presentation. Larger scale studies are warranted to understand the pathophysiology of the disease and to find optimal management.
Acknowledgements: Partial support by the National Science Fund.

PB1694

PREDICTIVE RELEVANCE OF CLINICAL CHARACTERISTICS IN PEDIATRIC PATIENTS WITH RELAPSED ACUTE MYELOID LEUKEMIA TREATED AT SINGLE INSTITUTION– REPORT OF AN OUTCOME ANALYSIS

S. Al-Sweedan[1,2,*], K. Siddiqui[1], R. Jafri[1], I. Ghemlas[1], A. Al-Ahmari[1], A. Al-Seraihy [1]

[1]Pediatric Hematology/Oncology, King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [2]Pediatrics, Jordan University of Science & Technology, Irbid, Jordan

Background: Western hospitals have achieved First Complete Remission (CR-1) and Overall Survival (OS) rates of 90% and 60% for children with Acute Myeloid Leukemia (AML). Intensified regimens of standard chemotherapy along with precise risk classification and improvements in supportive care are mainly attributed to this achievement.
Aims: We analyzed clinical data of our pediatric AML patients treated at KFSH&RC from 2005 to 2015 in order to assess the outcome of our treatment efforts including Hematopoietic Stem Cell Transplantation (HSCT).
Methods: A total of 155 pediatric patients with AML were registered at our institution from 2005 to 2015. 55.5% (86) were boys with a F:M ratio 1:1.2 and median age at diagnosis 5.5 years (Min: 1.3months, Max: 13.8 years). 12 patients were excluded from further analysis for not being able to complete induction at our institution. 7% (10 of 143) had Down 's syndrome, 7.7% (11 of 143) had concomitant malignancies. 85.7% (120 of 140) were CNS-1, 27.4% (20 of 73) had MLL Gene rearrangement, 21.2% (14 of 66) were positive for TEL AML/RUNX1/RUNX1T1 and 22% (13 of 59) had PML/RAR (+). Trisomy 4, 10 or 17 was not seen among any of 13 patients tested. Most commonly observed FAB classification was M-5 (23.5%, 24 of 102) followed by M-2 (18.6%). 27.3% (39) were Low Risk, 43.4% (62) Intermediate and 29.4%(42) High Risk. 43.3% (58 of 134) received HSCT.
Results: Our CR-1 rate was 93.7% (134 of 143) with 100% in Low Risk, 95.2% Intermediate Risk and 85.7% in High Risk patients (P-Value: 0.023), requiring 1-3 cycles of chemotherapy with a median time of 1.3 months. Treatment Failure was observed in 6.3% (9 of 143). Relapse rates was 38.8%(52 of 134). Most common site of relapse was bone marrow (75%, 39 of 52). PML/RAR (P-Value: 0.044), Post-Induction BM Classification M-3 (P-Value: 0.034) and AML High Risk (P-Value: 0.003) were found to be significantly associated with Relapse. Age at diagnosis, or Time to CR-1 were not found to have any association with relapse. 51.9% (27 of 52) who relapsed, went for HSCT. With a median follow-up of 68.8 months, five year overall survival for our cohort of patients was (0.567±0.046); significantly poor (P-Value: 0.001) in relapsed (n=52, 0.137±0.051) compared to non-relapsed (n=82, 0.863±0.041); resulting in a five year event free survival of 0.472±0.044. Among relapsed group (n=52), five year overall survival was significantly better (0.160±0.073) for those who received HSCT (27) than who did not (n=25, 0.114±0.073, P-Value: 0.029). Five year overall survival was also significantly better for Non-Relapse group (n=31, 0.828±0.070) compared to relapsed patients (n=27, 0.160±0.073, P-Value=0.001) for whom HSCT was administered (n=58)
Summary/Conclusions: The results of our treatment efforts are in conformity with the western literature. Precise risk classification can be a vital predictor in planning for first line and salvage therapies including HSCT for pediatric patients with AML.

PB1695

IS HIF-2 ALPHA A POOR PROGNOSIS FACTOR IN HUMAN ACUTE MYELOID LEUKEMIA? A SINGLE CENTER ANALYSIS - PRELIMINARY RESULTS

J. Dybko[1,*], D. Urbaniak-Kujda[1], D. Szymczak[1], O. Haus[1,2], B. Jaźwiec[1], M. Sawicki[1], T. Wróbel[1], K. Kuliczkowski[1]
[1]Hematology and Bone Marrow Transplantation, Wroclaw Medical University, Wroclaw, [2]Department of Clinical Genetics, Collegium Medicum , Nicolaus Copernicus University, Bydgoszcz, Poland

Background: Hypoxia-inducible transcription factors (HIF) are well known regulators of cellular response to hypoxia. HIFs control functional, metabolic and vascular adaptation to hypoxia on transcriptional level. HIF-1 alpha has been also described to be responsible for solid tumors chemoresistance, invasion, metastasis and relapse. The role of HIFs in leukemias has not been established well so far. First reports of poor outcomes of antileukemic treatment linked with overexpression of HIF-1α has been published. Moreover another HIF subunit - HIF-2 alpha - has been described in mouse model as increasing myeloid preleukemic cell proliferation and accelerating disease progression with reduced survival. On this background, we found interesting if HIF-s alpha expression in acute myeloid leukemia cells (AML) influences the prognosis in human. We have tried to find a connection between AML cells percentage expressing HIF-2 alpha and first line chemotherapy results.
Aims: The aim of the study was to determine the roole of HIF-2 alpha in human AML.
Methods: We analyzed a 26 primary AML patients group (median age 54.5 (21-77), F/M – 13/13). The group consisted of 21 AML-NOS cases, 2 AML cases with inv(16), one case with t(6;9) and one with t(9;11) according WHO classification. ELN cytogenetic risk stratification divided the group into intermdiate-1, intermediate-2 and adverse cases in 10, 12 and 4 patients respectively. All patients were treated with Daunorubicine, Cytarabine and Cladribine based first line chemotherapy. We collect bone marrow and blood samples before chemotherapy and blood samples alone 48 hours after chemotherapy start. In all samples leukemic blasts were counted and determined by flow cytometry and the subpopulation of HIF-2 alpha positive blasts was estimated as well. Volunteer bone marrow donors were the control group in this study and the CD34+HIF-2α+ subpopulation was assessed in their bone marrow samples during the routine harvest procedure. The study was approved by the local Ethics Committee.
Results: After the first line chemotherapy 15 patients achieved complete remission (CR group) and 11 did not (NR group). We did not find significant differences between the groups regarding patients age, the mean percentage of blasts in bone marrow and blood before the treatment, the percentage of HIF-2 alpha positive blasts in BM and blood before and 48 hours after the treatment start (data not shown). But the analysis of the percentage of HIF-2 alpha positive blasts in blood before and 48 hours separately in CR and NR groups revealed quite different dynamics. In CR group the mean percentage of HIF-2 alpha positive blasts was 14.65 (±33.32) and 8.48 (±11.63) before and after chemotherapy respectively (p=NS); in NR group the values were 11.74 (±22.6) and 24.01 (±33.68) respectively (p=0.007) (Figure 1). The Cox analysis revealed HIF-2 alpha positive blasts in blood after chemotherapy to be proportional to death probability (p=0.0036) (Figure 2).

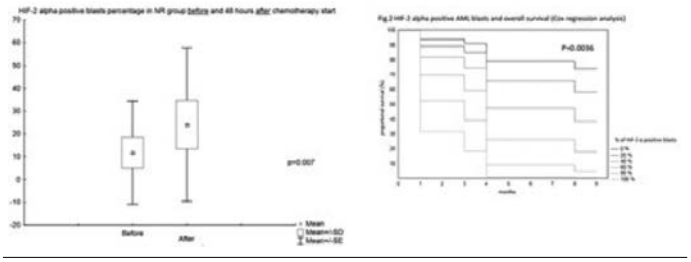

Figure and 2.

Summary/Conclusions: We are aware our results are preliminary. But if they are confirmed it will be very interesting to determine the role of HIF-2 alpha inhibitors in improving the prognosis and survival in human AML.

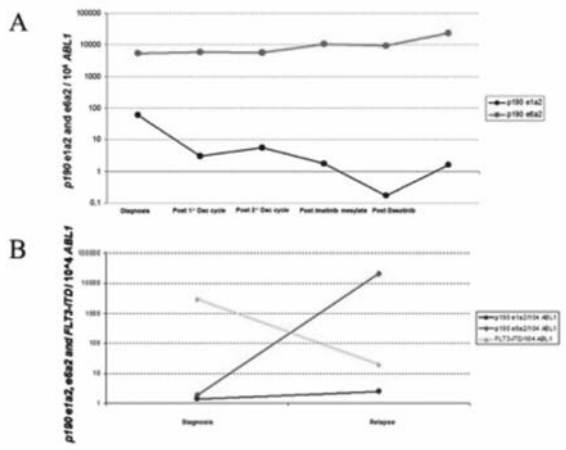
PB1696

RARE BCR/ABL FUSION PROTEINS AND THEIR CLINICAL SIGNIFICANCE INTO PH+ ACUTE MYELOID LEUKEMIAS

M. Piedimonte[1,*], T. Ottone[2], V. Alfonso[2], A. Ferrari[1], E. Conte[1], M. Divona[2], M. P. Bianchi[1], M. R. Ricciardi[1], S. Mirabilii[1], R. Licchetta[1], F. Falco[1], A. Campagna[1], L. Cicconi[2], G. Galassi[1], S. Pelliccia[1], A. Leporace[1], F. Lo Coco[2], A. Tafuri[1]
[1]Department of Clinical and Molecular Medicine & Sant'Andrea AOU, Sapienza University of Rome, [2]Department of Biomedicine and Prevention, University of Tor Vergata, Rome, Italy

Background: The Philadelphia (Ph) t(9;22)(q34;q11) results in an oncogenic *BCR/ABL* gene fusion, representing the hallmark of chronic myeloid leukemia (CML), although it has been also described in acute lymphoblatic (ALL) and myeloid (AML) leukemia. Three main different transcripts have been described (p210, p190 and p230), but rare atypical *BCR* breakpoints outside the cluster regions have been also reported and their clinical significance is under investigation. Atypical transcript p190 e6a2 is a rare fusion protein associated with aggressive phenotype and dismal prognosis. The breakpoint in *BCR* intron 6 is responsible for increased kinase activity and greater transforming potential because of the partial loss of the Guanine Exchange Factor (GEF)/dbl-like domain, completely absent in p190 proteins. This truncation could increase the BCR/ABL oncogenic activity.
Aims: In this report we describe 2 rare cases of Ph+ AML patients with the atypical p190 e6a2 isoform.
Methods: Routine morphologic, immunophenotypic and genetic analyses were carried out in all samples at diagnosis. cDNA extracted from bone marrow was synthesized from 1 µg of total RNA. Most common AML genetic alterations were investigated and a quantitative RT-PCR (qRT-PCR) for p190 transcripts was performed. qRT-PCR assay for *FLT3*-ITD and p190 e6a2 transcript were developed.
Results: Case 1. A 78-years old male was admitted at our hospital with clinical and laboratory features allowing to make the diagnosis of AML. No evidence of a preceding CML (splenomegaly or basophilia) was found. The karyotype on G-banded metaphases was 46,XY, t(9;22)(q34;q11). While the molecular analysis was ongoing, the patient started treatment based on decitabine. The molecular biology analysis revealed the simultaneous presence of the common p190 e1a2 and the rare e6a2 isoforms (Figure 1A). Because of persisted pancytopenia and presence of blasts, according to the molecular data, he was then switched to TKIs treatment. Nevertheless, after 2 months, the patient was still refractory to second line treatment dying because of a pulmonary infection. Case 2. A 61-years old male was admitted with a diagnosis of AML 46XY, *FLT3*-ITD post MDS. Immediately, after cytoreduction, chemotherapy was started, obtaining the complete remission. Because of infectious complications, the

consolidation chemotherapy was postponed, relapsing without reach the already planned allogeneic transplantation. At the relapse karyotype was 46XY, t(9;22)(q34;q11) and the molecular biology showed the presence of p190 e1a2 and e6a2 isoforms and *FLT3*-ITD mutations with a low mutant allelic burden (Figure 1B). Salvage chemotherapy was then performed, allowing at this time to obtain disease remission and further allogeneic transplantation. Nevertheless, the patient died 5 months later for transplant complications. qRT-PCR assays performed in diagnosis sample showed the main clone *FLT3*-ITD accompanied by subclones with p190 e1a2 and e6a2 isoforms. These data indicate a clonal selection process and the expansion of a resistant clone with p190 e6a2.



Kinetic's comparison of P190 e1a2, e6a2 and *FLT3*-ITD transcripts in (A) UPN1 and (B) UPN2. Dac: Decitabine

Figure 1.

Summary/Conclusions: The atypical p190 e6a2 transcript seems to be associated in AML with aggressive disease. TKI therapy alone does not seem to control the disease. Prompt observations on these patients carrying rare *BCR/ABL* transcripts may allow help to establish optimal treatment approaches on these aggressive BCR/ABL phenotypes.

PB1697

HYPOMETILATING AGENTS AS SALVAGE THERAPY IN RELAPSED OR REFRACTORY AML: A 2-CENTERS RETROSPECTIVE STUDY

F. Lessi[1,*], A. Branca[1], M. Laurino[1], D. Lazzarotto[2], C. Filì[2], A. Candoni[2], G. Semenzato[1]
[1]Department of Medicine, University of Padua, Hematology and Clinical Immunology Unit, Padova, [2]Division of Hematology and Bone Marrow Transplantation, Azienda Sanitaria-Universitaria Integrata, University of Udine, Udine, Italy

Background: 5-azacytidine and decitabine have been widely studied as first line chemotherapy in acute myeloid leukemia (AML) patients not eligible for allogenic stem cell transplantation, but data on their use as salvage chemotherapy are limited.
Aims: To define efficacy and feasibility of hypometilating agents (HMA) as salvage chemotherapy in patients without previous allogenic stem cell transplantation.
Methods: We retrospectively reviewed clinical records of 15 patients treated with HMA as salvage therapy in our institutions since their introduction in clinical practice for AML patients.
Results: Median age was 66 years. Six patients were men and 9 women. One patient was AML with t(8;21), 7 were AML MRC, 1 was therapy related AML, 6 were AML NOS. Two patients were favorable risk sec ELN 2010, 11 were intermediate I and II and 2 were adverse risk. 67% of patients received HMA as second line therapy for their disease, 27% as third line and 6% were beyond the third line. Seven patients were treated with decitabine and 8 with azacitidine. Five patients reached CR or CRi after HMA. All patients underwent intensive chemotherapy (*i.e.* FLAI like or 3+7 like) as first line induction, and we excluded patients who had a HMA as first line chemotherapy and another one as second line. Median number of hospitalization days during HMA therapy was 16; median number of HMA cycles was 2 (range 1-31). 26% of patients underwent allogenic stem cell transplantation after HMA therapy. Median OS was 197 days from the starting of HMA and median EFS was 70 days. Median OS in patients with refractory disease was 91 days and median OS in relapsed patients was 331 days (p=0,0049). Median EFS in patients with refractory disease was 57 days and median EFS in patients with relapsed disease was 198 days (p=0,039). We did not find significant differences between transfusion needs before and after salvage therapy but this could be due to the small size of our sample.
Summary/Conclusions: HMA showed efficacy and a considerable OS in our patients. In our cohort refractory patients were almost all refractory to HMA too, and their OS was dismal. So HMA could be a good clinical option in a selected population of relapsed patients, especially in those not suitable for allogenic bone marrow transplantation, in whom the prognosis is generally extremely poor. Further studies are needed to determine which are the cytogenetic subsets of patients who could benefit from such a salvage chemotherapy.

PB1698

OMITTING CYTARABINE FROM CHEMOTHERAPY FOR ACUTE PROMYELOCYTIC LEUKEMIA REDUCES TOXICITY AND NOT EFFICACY

C. Lalayanni[1], G. Karavalakis[1,*], E. Gavriilaki[1], A. Lazaridou[1], M. Iskas[1], A. Syrigou[1], M. Papathanasiou[1], G. Papaioannou[1], A. Athanasiadou[1], A. Papalexandri[1], C. Vadikoliou[1], N. Stavroyianni[1], R. Saloum[1], A. Anagnostopoulos[1]
[1]Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: The introduction of retinoic acid (ATRA) has changed the treatment paradigm in Acute Promyelocytic Leukemia (APL). Combination of ATRA plus anthracycline-based induction (AIDA) without cytarabine (AraC) has shown high efficacy in Spanish and Italian studies. However, early mortality resulting from coagulation disorders remains high. Furthermore, AraC administration during consolidation is questioned and often limited to high-risk patients.
Aims: We aim to compare the efficacy, tolerance and toxicity between 2 consecutive treatment protocols that differed in AraC administration during consolidation.
Methods: We studied clinical characteristics, prognostic factors, response to treatment, tolerance, toxicity and outcomes in APL patients treated in our Department during the last decade. All patients received induction with AIDA (Idarubicin x4, ATRA until remission) and 2-year maintenance therapy. Protocol 1 included 2 cycles of consolidation with anthracyclines/AraC. Protocol 2 was implemented the last 5 years and included 3 cycles of anthracyclines and AraC only in high-risk patients (PETHEMA LPA2005).
Results: APL was diagnosed in 35 patients, of whom 2 patients older than 80 years did not receive treatment and were not included in the analysis. The rest 18 male: 15 female patients aged 37 (10-75) years old presented at diagnosis with: thrombocytopenia (32), leukopenia (22), leukocytosis (6), impaired performance status/PS >2 (10), lactate dehydrogenase >400 IU (17), increased d-dimers (33), low fibrinogen (11), fibirinogen <1 mg/dl (5). Five patients died during induction from severe differentiation syndrome (2), bleeding (2) and infection (1). In the multivariate analysis, these patients had significantly impaired PS (3, p=0.005), older age (median of 59 years, p=0.014) and lower fibrinogen (median of 0.9 mg/dl, p=0.05). Among 28 patients eligible for the comparison, all patients achieved complete remission (CR=100%). Protocol 1 (AraC) was applied to 16 patients and 2 to 12 patients. Complete molecular remission was achieved after a median of 2 chemotherapies (1-3). Efficacy could not be compared between protocols because there was only 1 relapse in Protocol 2, refractory to chemotherapy, ATRA, arsenic trioxide and allogeneic transplantation. However, there were significant differences in tolerance and toxicity. Patients in Protocol 1 had significantly higher transfusion needs compared to Protocol 2(p<0.001): 9(2-15) *versus* 1(0-17) red blood cell and 11(3-32) *versus* 2(0-10) platelet transfusion. Duration of grade 4 leukopenia was significantly higher in Protocol 1 [16(5-19) *versus* 9(0-18) days, p=0.002]. The same was true for neutropenia (p=0.04) and resulted to higher infection rates in Protocol 1 (58% *versus* 17%, p=0.03), including 2 aspergilloses and 1 fatal sepsis. 10-year overall survival probability was 73.1%, with no difference between Protocols.
Summary/Conclusions: Our study confirms that early mortality is a significant issue in APL, in particular for older patients. AraC can be safely omitted from treatment of low- and intermediate-risk patients, resulting in significantly reduced toxicity.

PB1699

DISEASE CHARACTERISTICS AND TREATMENT PATTERNS OF AML PATIENTS <60 YEARS OLD *VERSUS* ≥60 YEARS OLD

B.C. Medeiros[1,*], B. Pandya[2], A. Hadfield[3], S. Wilson[2], C. Bui[2], T. Bailey[3], S. Flanders[2], A. Rider[3], L. Horvath[2], J. Pike[3]
[1]Stanford University, Stanford, [2]Astellas Pharma Inc., Northbrook, United States, [3]Adelphi Real World, Cheshire, United Kingdom

Background: There is limited real-world data in patients with acute myeloid leukemia (AML) that looks at presenting disease characteristics and subsequent treatment decisions made for patients <60 and ≥60 years of age in the United States (US).
Aims: This analysis examined the characteristics of patients <60 years of age and ≥60 years of age at the point of AML diagnosis and further investigated subsequent treatments.
Methods: Data from the Adelphi AML Disease Specific Programme, a real-world, cross-sectional survey conducted between February–May 2015, were analyzed. A total of 61 hematologist/oncologists provided data on their 457 AML patients treated at various stages of AML. Disease characteristics upon

initial AML diagnosis including symptoms, performance status, and physician-determined prognostic category were taken from physician-completed patient record forms. Details about subsequently prescribed AML treatment were also taken from this data source. Treatments for n=15 (3.3%) patients were reassigned as high or low intensity following evaluation of physician treatment selection. Post-hoc T-tests and Chi-Squared/Fisher's exact tests were used to determine differences between groups.

Results: Table 1 shows key presenting characteristics of AML patients <60 and ≥60 years old. According to physicians, those patients <60 years of age were significantly more likely than those ≥60 years of age to have de novo AML, a performance score of 0 *versus* ≥1 at diagnosis, more tests conducted to establish the diagnosis and a more favorable prognosis at baseline, according to physician perception. Following initial diagnosis, patients <60 years of age were 1.65 times more likely than patients ≥60 years of age to be initiated on high-intensity induction treatment: 67% (n=143) of patients <60 years of age compared to 40% (n=98) of patients ≥60 years of age (high *versus* low intensity by age group *P* <0.001). All other patients received low intensity treatment. Irrespective of age, the most common high intensity treatment given was a cytarabine-based regimen and the most common low intensity treatments were low dose cytarabine-, decitabine- or azacitidine-based regimens.

Table 1. Disease characteristics of patients <60 and ≥60 years of age at diagnosis of AML.

Disease characteristics		<60 years old (n=214)	≥60 years old (n=243)	*P*-value
Gender	Male	128 (60%)	127 (52%)	0.106
Pathophysiology	De novo	206 (96%)	209 (86%)	<0.001
Symptoms	No. of symptoms at diagnosis [mean (SD)]	3.5 (3.3)	3.2 (2.9)	0.307
Performance status	ECOG score at diagnosis – 0 (Fully active, able to carry on all pre-disease performance without restriction)	81 (38%)	43 (18%)	<0.001
Diagnostic tests	No. of tests used to establish AML diagnosis [mean (SD)]	5.5 (3.6)	4.7 (3.6)	0.025
Physician-defined prognostic category	Favorable	101 (47%)	54 (22%)	<0.001
	Intermediate	84 (39%)	122 (50%)	
	Poor	22 (10%)	55 (23%)	
	Not determined	7 (3%)	12 (5%)	

Summary/Conclusions: The age of an AML patient at initial diagnosis appeared to play a significant role in the diagnostic, prognostic and treatment intensity decisions made by AML-treating physicians in the US. The estimated performance and prognostic status' tend to be considerably better for younger patients and consequently, they were more likely to receive the most aggressive yet more effective high intensity treatments currently available to treat AML.

PB1700

FLT3, NPM1, CEBPA AND TP53 MUTATIONS AT ACUTE PROMYELOCYTIC LEUKEMIA: PROGNOSTIC FACTORS AND CORRELATION WITH OTHER MARKERS WITHIN THE PATIENTS OF GOMEL REGION IN BELARUS

Z. Kozich[1,*], V. Martinkov[2], A. Silin[2], I. Tropashko[2]
[1]Hematology, [2]Molecular Genetics, The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus

Background: Acute Promyelocytic Leukemia (APL) is one of the favourable variant of acute myelocytic leukemias due to the usage of ATRA in the treatment simaltenously with chemotherapy. But relapses occur in 13-33% cases after achievement the remission and there are cases of early death from the bleeding. High leukocytosis, the presence of lymphoid immunophenotypic markers and gene mutations are important prognostic factors.

Aims: To examine prognostic factors in APL

Methods: The materials for research were the samples of whole venous blood and bone marrow of 40 patients with APL treated in the period of 2009-20016 in Hematology department for adults, Gomel. The diagnosis was proved by the presence t(15;17) or PML/RARA. Induction therapy was carried out according to the protocol «7+3» using ATRA. Immunophenotypic analysis was carried out by standard immunofluorescence methods. The method of polymerase chain reaction (PCR) with specific primer and following electrophoretic detection was used for recognition of gene mutations.

Results: Out of 40 examined patients (mean age 48,5),80%(32) achieved remission and 15.6%(5) subsequently relapsed after the first course of chemotherapy. Clinical, laboratory, molecular genetic and immunophenotypic data which could affect remission results and general survival rate were analyzed within all the patients. As a result, mutations were detected in 55% of cases. FLT3-ITD mutations were detected in 32,5%(13), NPM1 mutations in 12,5%(5), combination of FLT3-ITD and NPM1 in 7,5%(3), TP53 and CEBPA mutations were detected in 5%(2) and 12,5%(5) of cases respectively. After achievement of remission after the first course of chemotherapy NPM1 mutation remained at 6.2%(2). Mutations were identified more frequently within the patients with the absence of response to the therapy or with the developed relapse in a while. The worst prognosis had the patients with the combination of FLT3-ITD and NPM1 mutations. There were the patients with high leukocytosis, presence of CD56 and CD2 immunophenotypic markers, who didn't achieve remission or had the recurrence when the treatment was dropped. The presence of leukocytosis was detected in 25% of cases, in 90% (9/10) of cases leukocytosis was combined with FLT3-ITD mutations and 80% of these patients subsequently had the recurrence. Within the patients with the combination of FLT3-ITD and NPM1 mutations who brought into remission after the first course of chemotherapy these mutations were not detected later on. There were the patients who had leukocytosis rate less than 20x10 9 * \ l and didn't have CD56 and CD2(11,5%) at the time of verification. The presence of TP53 mutation was combined with high leukocytosis of the patient and with the absence of effect on the conducted therapy. When analyzing the immunophenotypic markers CD56 and CD2, they were detected in 75% of the patients, but in the absence of gene mutations and leukocytosis, such patients had a favorable prognosis (16,7%(3/18, p=0,046)).

Summary/Conclusions: Our results prove that the presence of only one of the signs is not a factor of high risk. Only combination of clinical, laboratory, molecular-genetic and immunophenotypic markers can include the patients into a high risk group and influence general survival rate.

PB1701

A UNIQUE PRESENTATION OF ACUTE PROMYELOCYTIC LEUKEMIA: AORTOILIAC OCCLUSIVE DISEASE (LERICHE SYNDROME)

S. Berk[1,*], M. Günaltılı[2], S. Sadri[1], A. E. Eşkazan[1], Z. Başlar[1], T. Soysal[1]
[1]Haematology, [2]Internal Medicine, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Acute promyelocytic leukemia (APL), FAB M3 subgroup of acute myeloid leukemia is known for its association with haemostatic disorders. Compared to bleeding thrombosis is a less commonly encountered complication of APL. Thrombosis of major arteries is a rare form of presentation.

Aims: A case, who applied with acute lower limb ischemia and diagnosed with APL and aortoiliac occlusive disease (Leriche syndrome), is presented.

Methods: A 53-year-old female patient presented with weakness, loss of appetite and pain in the lower extremities. She had diabetes mellitus (DM) regulated with metformin, hyperlipidemia (HL), and smoking history. Physical examination revealed general paleness and ischemia around big toe of the right foot. Laboratory studies revealed leukopenia, neutropenia, anemia, thrombocytopenia, elevated D-Dimer. A bone marrow aspiration and biopsy was done to enlighten the etiology of pancytopenia. The pathological examination of the bone marrow revealed abundant granular blasts (78%) and Auer rodes. The patient was diagnosed with APL, hypergranular classical form. t(15;17) was positive with fluorescence *in situ* hybridization. All-trans retinoic acid (ATRA) plus idarubicin treatment was started. In few days findings of ischemia progressed and encompassed 2nd, 4th and 5th toes together with the big toe (Figure 1 on the left). Monophasic flow pattern (proximal stenosis?) was detected in bilateral common femoral arteries in lower extremity venous doppler ultrasonography. On CT angiography, abdominal aorta and bilateral common iliac arteries were observed to be occluded from L3 vertebra level till 1.5 cm after aortic bifurcation (Figure 1 on the right). Low-molecular-weight heparin therapy was started. According to rheumatological tests and tests for lupus anticoagulant, anticardiolipin and antiphospholipid antibodies, anti-beta-2 glycoprotein-1, protein C-S, Antithrombin III and homocysteine levels, methylenetetrahydrofolate reductase, Factor V Leiden and prothrombin gene mutations no cause of tendency to thrombophilia could be determined. Echocardiography was normal. The patient was transferred to Cardiovascular Surgery Department for axillofemoral bypass operation.

Figure 1.

Results: In APL 80% of thrombotic events occur before treatment or during induction. Acute lower limb ischemia as an initial feature of APL is very rare

which makes our case unique. Thrombotic risk factors in APL include high leukocyte count, presence of coagulation disorder, ATRA+chemotherapy+ antifibrinolytic therapy and ATRA syndrome. None of these were seen in the presented case. The effects of known predisposing risk factors to thrombosis meaning DM, HL and smoking cannot be ruled out. But development of acute thrombosis concomitant with APL diagnosis points out to the relationship between these two entities.

Summary/Conclusions: Current literature knowledge is based on case reports and 9 patients with APL who presented with acute lower limb ischemia were reported yet. As far as we know our case is the first APL case presenting with aortoiliac occlusive disease (Leriche syndrome).

PB1702

A CASE OF THERAPY-RELATED ACUTE LEUKEMIA WITH MIXED PHENOTYPE WITH BCR-ABL1 AFTER TREATMENT OF DIFFUSE LARGE B-CELL LYMPHOMA

D. Yang[1,*], J. Lee[2], S. R. Cho[3], Y. S. Kim[4], J. R. Choi[5], M. H. Kim[1]
[1]Laboratory Medicine, Kosin University Gospel Hospital, Busan, [2]Yeongam-gun Public Health Center, Yeongam, [3]Laboratory Medicine, Ajou University School of Medicine, Suwon, [4]Internal Medicine, Kosin University Gospel Hospital, Busan, [5]Laboratory Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: Although therapy-related acute leukemia (tAL) is a well-recognized clinical syndrome and is increasing owing to the prolonged survival of patients treated with chemoradiotherapy, tAL with mixed phenotype is extremely rare.

Aims: Here, we report a rare case of tAL with mixed phenotype with *BCR-ABL1* after achieving complete remission (CR) of Diffuse Large B-Cell Lymphoma (DLBCL).

Methods: A 57-year-old woman was diagnosed as DLBCL. The patient received six cycles of R-CHOP regimen with G-CSF injected after each cycle and achieved CR. The patient was readmitted to the hospital after a follow-up examination revealed the presence of immature cells in the blood.

Results: Her complete blood count findings were as follows: hematocrit, 35.1%; hemoglobin, 116 g/L; platelet count, 129×10^9/L; and white bloodcellcount, 2.41×10^9/L, with 4% blasts, 26% segmented neutrophils, 3% band neutrophils, 39% lymphocytes, and 26% monocytes. Bone marrow aspirations mears revealed 40.7% leukemic blasts with medium cell size, ovaltoround shape, vesicular nuclei, fine chromatin patterns, and basophilic cytoplasm. On cytochemical staining, these blast cells were not positive on PAS and NSE staining, but were weakly positive for MPO staining. Flow cytometric analysis showed that the blasts were positive forboth T-lymphoid and myeloid markers (cytoplasmic CD 3,87%; CD 5,90%; CD 7,96%; cytoplasmic myeloperoxidase, 20%; CD 13,91%; CD 33,87%) and negative for CD2, CD10, CD11b, CD14, CD15, CD19, CD20, CD61, CD117, and TDT. Immuno phenotyping ful filled the diagnostic criteria of T/myeloid biphenotypic leukemia based on the scoring system of the EGIL and WHO classifications. Multiplex reverse transcription PCRusing Hema Visionkit (Bio-Rad Laboratories) revealed the presence of minor *BCR-ABL1* (*e1a2*) fusion transcripts. Chromosome analysis of bone marrow cells failed because of insufficient mitotic cells. Immunoglobulin heavy chain gene rearrangement and TCR gene rearrangement were not detected on bone marrow aspirates.

Summary/Conclusions: Mixed phenotype acute leukemia is an uncommon subtype that comprises 0.5-1% of leukemia. The T/myeloid phenotype is rarer and represents 35% of all MPAL cases The risk of secondary malignancies after lymphoma treatment is relatively increased for leukemia. AML, ALL, MDS, CML and chronic myelomonocytic leukemia are reported secondary hematologic malignancies. Until now, only one case of tAL with mixed phenotype after lymphoma has been reported worldwide. To the best of our knowledge, this is the second case of tAL with mixed phenotype after DLBCL. This case is also unique because the *BCR-ABL1* has not been described in the literature for patients with tAL with mixed phenotype, after hematologic malignancy. According to the 2008 WHO classification, tAL can be attributed to radiation, alkylating agents, or topoisomerase II inhibitors. Our patient did not receive radiation therapy but previously received cyclophosphamide and doxorubicin. Therefore, this is the first case of tAL with mixed phenotype and *BCR-ABL 1* after alkylating agent and topoisomerase II inhibitor therapy for DLBCL.

PB1703

CROSS-SECTIONAL ANALYSIS OF CONCORDANCE RATES BETWEEN KARYOTYPING AND RT-PCR IN ACUTE MYELOID LEUKEMIA; REAL WORLD CHALLENGES

D. Katoch[1,*], Y. Uday[1], T. Verma[1], R. Kapoor[1], S. Das[1], V. Nair[1]
[1]Hematology, Army Hospital (Research & Referral), Delhi, India

Background: Translocation and chromosomal anomalies have prognostic implications in acute myeloid leukemia (AML). Cytogenetic analysis assumes great importance in their diagnosis and treatment stratification which are assessed by karyotyping and/or reverse transcriptase polymerase chain reaction (RT-PCR). Given the dependency of karyotyping on sample quality, more and more centers are now relying on RT-PCR to detect specific translocations. Varying rates of concordance between Karyotyping and RT-PCR have been reported and no consensus has prevailed. Given the resource constraint, it is economically non-viable to perform both for prognosis in real world scenarios. In addition, the cost of the extra tests also adds to the burden of healthcare economy.

Aims: In 132 patients of AML, we aimed at determining the incidence of cytogenetic abnormalities and molecular anomalies detected by Karyotyping and RT-PCR respectively. Concordance rates between conventional cytogenetic tests and RT-PCR were also calculated.

Methods: We conducted a retrospective analysis on the medical records of 132 patients of AML at a tertiary health care facility in India, treated during 2010-2017. Results from commercially available molecular assays for detection of specific translocations by RT-PCR and of adequate samples of karyotype analysis were compared.

Results: In AML patients, out of those tested 50.6% had chromosomal aberrations detected by karyotyping while 30% had a positive detection with RT-PCR. The concordance rate in AML was found to be 56.3%. In a large number (31 in AML) karyotyping provided additional information in the form of detection of deletions, additions and hyper-diploidy (Table 1).

Table 1.

Incidence of various translocations in AML as detected by RT-PCR and Karyotyping

Type of Translocation	Incidence using RT-PCR (%) (n = 90)	Incidence using Karyotype (%) (n = 83)
Inv (16)	2.32	1.17
t (8;21)	14.47	9.75
t (15;17)	17.33	8.53

Summary/Conclusions: RT-PCR cannot substitute conventional cytogenetic analysis due to the absence of a broad based application for detection of aberrations other than translocations. However, given its efficiency and reliability it can have a complimentary role in prognosis assessment.

PB1704

CLINICAL, CYTOMORPHOLOGIC AND IMMUNOPHENO/IMMUNOHISTOCHEMICAL CHARACTERISTICS OF PATIENTS WITH BLASTIC PLASMOCYTOID DENDRITIC CELL NEOPLASM - DIAGNOSTIC AND THERAPEUTIC DILEMMA

A. Vidovic[1,*], M. Virijevic[1], D. Tomin[1], N. Suvajdzic Vukovic[1], V. Milosevic[1], I. Djunic[1], M. Mitrovic[1], N. Colovic[1], N. Kraguljac Kurtovic[1], M. Perunicic Jovanovic[1], B. Mihaljevic[1]
[1]Clinic of Hematology, Clinical Center of Serbia, University of Belgrade, Belgrade, Serbia

Background: Blastic plasmocytoid dendritic cell neoplasm (BPDCN) is a clinically aggressive haematological malignancy that originates from clonal proliferation of plasmocytoid dendritic cells and their precursors. BPDCN is rare, represents less than 1% of acute leukemias. The disease has two patterns of presentations: cutaneus and leukemic. The main histological differential diagnosis includes: cutaneous NK/T-cell lymphoma; cutaneous T-cell lymphoma with co-expression of CD56 and CD56+ acute myeloid leukemia with monocytic differentiation.

Aims: The aim of study was to analyze heterogeneity of BPDCN differential diagnosis, especially with regards to clinical, immunological and cytomorphological characteristics of blastoid cells in terms of the optimal treatment.

Methods: During period 2010-2016. at the Clinic of Hematology, eight patients with BPDCN were diagnosed (M/F 6/2; average age 38 yrs, range 26-60yrs). In the blood count, average concentration of Hb was 108g/l (range 87-154); WBC 6,38x10e9/l (range 2,6-12); Plt 147,8x10e9/l (range 20-282). Hemorrhagic diathesis was registered in 3/8; splenomegaly in 6/8 (average diameter by ultrasound exam 140mm, 110-150mm); and hepatomegaly existed in 3/8 pts (average diameter 166mm, 140-200mm). Cutaneous infiltrations were present in 5/8 pts as livid maculopapular rash along lower extremities in 5 pts, and in 1 female pts in the breast region of 1-4cm diameter. In all 5 pts, immunocytochemistry confirmed BPDCN diagnosis. In the bone marrow aspirates of 7/8 pts, average 75% infiltration (27-89%) with blasts was revealed. Cells were of median size, with high nucleus cytoplasm ratio, with visible oval or slightly imprinted nucleoli. Basic immunophenotype profile was characterised by expression of $CD56^+CD4^+CD123^{+high}$ $CD45RA^+$, and negativity for $CMPO^-$ $cCD79a^-$ cCD3c- in 4 cases. Immunohistochemitry staining in the rest of 4 pts, characterized with dry aspiration, revealed LCA+CD43+CD56+CD4+ CD33+ positivity and MPO- TDt-CD34 -CD117- CD68- HLADR-negativity. Only 1 pts had CD4 negativity. Cytogenetic analysis revealed normal karyotype in 4 pts, while the rest of 4 pts had pathological findings: 1. 92,XX, XY; 2. 80-120,XXYY,+ mar (16)/46XY; 3. 46XY,del 5q/46XY; and 4. 46XX,del 12p, respectively.

Results: Four pts were treated with 3+7 chemotherapy. Complete remission (CR) was achieved in 3 pts, and treatment was continued according to the HIDAC and IDAC protocol. The duration of remission was 3, 8 and 11 months respectively, followed with relapse and letal outcome. One of the pts died within first 0,5 months after BPDCN was diagnosed. Three pts, treated with Hyper-CVAD, are alive and in CR with duration of 1, 3 and 10 months respectively. The continuation of the treatment within the programme of allogeneic stem cell transplantation is planned in 2 pts.
Summary/Conclusions: BPDCN diagnostics is difficult due to the heterogeneity of immunological characteristics of disease. Aggressive course of disease with median survival of 12-18 months, in the view of the unique treatment recommendations indicates necessity of further clinical investigations on larger patients groups.

Aggressive Non-Hodgkin lymphoma - Clinical

PB1705

ECONOMIC IMPACT AND HEALTHCARE UTILIZATION IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA IN ROUTINE CLINICAL CARE IN THE UNITED STATES – A CLAIMS DATABASE STUDY

A. Galaznik[1,*], J. Bell[1], L. Hamilton[2], A. Ogbonnaya[2], K. Hennenfent[2], M. Eaddy[2], Y. Shou[1]
[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [2]Xcenda LLC, Palm Harbor, United States

Background: DLBCL is the most common histologic subtype of non-Hodgkin lymphoma (NHL), accounting for about 33% of all NHL cases. However, the healthcare burden associated with DLBCL has not been extensively studied in a US population.
Aims: We evaluated the costs of care and healthcare utilization (HCU) of DLBCL patients treated during routine care in the US.
Methods: The Optum claims database was used to identify adult patients (≥18 years old) with newly diagnosed DLBCL between 01/01/08 and 10/31/15. DLBCL diagnosis was based on ≥1 inpatient claim or ≥2 outpatient claims with DLBCL diagnosis codes, with the index date being the first DLBCL claim. Patients were followed from index date until end of continuous enrollment, death, or end of study period (12/31/15) for the assessment of HCU and costs. DLBCL-related and non-DLBCL-related HCU and costs incurred during follow-up were evaluated. DLBCL-related HCU and costs were medical claims with a primary diagnosis of DLBCL or DLBCL-related treatment (chemotherapy, radiation, stem cell transplant [SCT], supportive care) and pharmacy claims for DLBCL treatment. Proportions of patients with HCU were reported. Costs were calculated as per-patient-per-month (PPPM) costs and reported as mean and standard deviation (SD). Patients with a capitated payment plan were excluded from the cost analysis.
Results: 1,267 treated DLBCL patients were identified. Over the follow-up period, 66.0% of patients had ≥1 inpatient admission, with more patients having a non-DLBCL-related than DLBCL-related admission (Table 1). 60.0% of patients had ≥1 emergency room visit over the follow-up period; visits were predominately for non-DLBCL-related. Nearly all patients had ≥1 physician office visit (92.4%) and other outpatient visits (99.6%). The mean PPPM costs incurred during the follow-up period was $11,890 (SD: $11,515) (Table 1), and costs were higher in Year 1 ($14,402, SD: $10,951) than in Year 2 ($4,190, SD: $8,076). About 55% of costs overall were related to DLBCL medical services ($6,532 PPPM, SD: $6,457). DLBCL-related medical PPPM costs decreased substantially from Year 1 ($8,327, SD: $5,925) to Year 2 ($1,443, SD: $4,349). This decrease was driven by the decreases in chemotherapy and supportive care medical services from Year 1 to Year 2. Non-DLBCL-related medical costs accounted for about 42% of the overall PPPM costs ($4,955, SD: $7,210); and a decrease was observed from Year 1 ($5,640, SD: $7,468) to Year 2 ($2,447, SD: $5,456). Inpatient admission was the main component of non-DLBCL-related costs, and associated costs decreased from Year 1 to 2.

Table 1.

Healthcare Cost and Utilization Overall and Year 1 and Year 2 Post-index Date for Treated DLBCL Patients

Healthcare Resource Use, %*	Overall N=1,267		Year 1 N=1,267		Year 2 N=1,267	
Inpatient Visit (all)	836	66.0%	730	57.6%	174	21.0%
DLBCL-related	158	12.5%	149	11.8%	9	1.1%
Non-DLBCL-related	802	63.3%	688	54.3%	173	20.8%
ER Visit (all)	760	60.0%	616	48.6%	221	26.6%
DLBCL-related	40	3.2%	40	3.2%	1	0.1%
Non-DLBCL-related	751	59.3%	605	47.8%	220	26.5%

Radiation	$913	$3,100	$1,123	$3,308	$257	$1,515
Stem Cell Transplant	$192	$1,441	$170	$1,510	$228	$1,923

*DLBCL-related vs non-DLBCL-related are not mutually exclusive groups; patients could be in both categories, and percentages are relative to the overall "n" in the column as the denominator.
Key: ER = emergency room; DLBCL = diffuse large B-cell lymphoma; PPPM = per patient per month.

Summary/Conclusions: The economic burden associated with the treated DLBCL population is high, with the majority of costs incurred during the first year of diagnosis. Between the first and second year of diagnosis, costs decrease mainly because of the decrease in the DLBCL-related treatment costs. In addition, HCU for DLBCL-related services decreased in Year 1 *vs* Year 2.

PB1706

PHARMACOKINETICS OF RITUXIMAB IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

S. Rožman[1,2], I. Grabnar[2], S. Novaković[3], A. Mrhar[2], B. Jezersek Novakovic[4,*]
[1]Pharmacy Department, Institute Of Oncology Ljubljana, [2]Department of Biopharmaceutics and Pharmacokinetics, Faculty of Pharmacy, University of Ljubljana, [3]Department of Molecular Diagnostics, [4]Department of Medical Oncology, Institute Of Oncology Ljubljana, Ljubljana, Slovenia

Background: Rituximab dosing is based on evidence from clinical practice rather than from consideration of pharmacokinetics and factors influencing individual exposure. Clinical use of rituximab can be improved through a more individualized treatment.
Aims: The objective of this investigation was to typify rituximab pharmacokinetics in 29 newly diagnosed patients with the diffuse large B-cell lymphoma who received rituximab in combination with cyclophosphamide, doxorubicin, vincristine and methylprednisolone every three weeks. The association of rituximab pharmacokinetics with clinical outcome was also investigated.
Methods: Rituximab serum levels were defined by enzyme-linked immunosorbent assay and assessed by a population pharmacokinetic analysis applying the non-linear mixed effects modelling.
Results: A 2-compartment model comprising linear non-specific clearance of 0.252 (95% CI: 0.227 – 0.279) L/day and time-varying specific clearance of 0.278 (95% CI: 0.181 – 0.390) L/day, corresponding to target-mediated drug disposition of rituximab was recognised to best describe the data. The nonspecific clearance was found to be lower in older patients and those with lower body weight. Additionally, the central compartment volume was higher in males. An unambiguous association of clinical response with rituximab pharmacokinetics has been detected. The rate constant of specific clearance decay was 0.143 day^{-1} (95% CI: 0.0478 – 0.418) in patients with no disease progression, while in patients with disease progression it was 82.2% lower (95% CI: 33.4 – 95.0).
Summary/Conclusions: These results imply that time-changes in clearance could serve as a predictive marker of response to rituximab. Our findings prove the rationale for studies evaluating higher doses of rituximab in selected patients.

PB1707

HOW 18FDG PET/CT CAN IDENTIFY BONE MARROW INFILTRATION IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA

C. Mainolfi[1,*], T. Mannarino[1], L. Marano[2], F. Trastulli[2], L. Simeone[2], O. Vitagliano[2], M. Memoli[2], S. Leone[2], F. Cacace[2], C. Mortaruolo[2], S. Pellegrino[1], M. Petretta[3], S. Del Vecchio[1]
[1]Department of Advanced Biomedical Sciences, [2]Department of Clinical Medicine and Surgery, [3]Department of Translational Medical Sciences, University Federico II, Naples, Italy, AOU Federico II Naples, Naples, Italy

Background: Bone marrow infiltration (BMI) evaluation plays a key role in lymphoma staging, treatment and prognosis. The role of PET/CT in the assessment of BMI is still controversial, especially in non-Hodgkin's lymphoma (NHL).
Aims: To evaluate the role of 18F-FDG PET/TC in bone marrow infiltration for the diagnosis of Non Hodgkin Lymphoma. We compared 18F-FDG PET/TC visual and quantitative analyses with bone marrow biopsy in NHL patients.
Methods: Fifty patients with newly diagnosed NHL from February 2011 to February 2016 were retrospectively analyzed. Of these, 26 (group A) patients had aggressive NHL and 24 (group B) indolent NHL. To detect BMI on the posterior iliac crest 3 different PET/CT evaluation methods were used: 1) visual analysis, 2) maximal standardized uptake values (SUVmax, cut-off >2.5), and 3) Deauville score (categorical). Each method was applied in the whole patients cohort, in group A and in group B. Images were blindly reviewed separately by 3 nuclear medicine physicians. PET/CT results were compared with the bone marrow biopsy performed after imaging in all patients. Decision-curve analysis was used to evaluate the increment in net benefit (NB) obtained considering the Deauville score over a biopsy-all strategy.
Results: The prevalence of a positive biopsy was 38% in whole cohort, 19% in group A and 58% in group B. In the whole cohort, sensitivity, specificity and accuracy were 21%, 84% and 60% for visual analysis; 58%, 55% and 50% for SUVmax; and 47%, 81% and 68% for Deauville score. In group A, sensitivity, specificity and accuracy were 0%, 76% and 62%, for visual analysis; 40%, 52% and 50% for SUVmax; and 20%, 71% and 62% for Deauville score. In group B, sensitivity, specificity and accuracy were 29%, 100% and 58% for visual analysis; 64%, 60% and 62% for SUVmax; and 57%, 100% and 75% for Deauville score. At probability threshold equal to the prevalence of a positive biopsy, the increase in NB by Deauville score was 0.11 in the whole cohort, 0.02 in group A and 0.33 in group B. In this latter group, biopsying patients on the basis of the Deauville score is a strategy that reduced the biopsy rate by 24%, without missing any BMI.
Summary/Conclusions: FDG-PET/TC visual analysis has a limited value for detecting BMI in patients with NHL, while quantitative analysis by Deauville score provides a higher diagnostic performance. Noteworthy, the high positive predictive value in patients with indolent NHL suggests a potential role of FDG-PET/TC in avoiding bone marrow biopsy in this subtype of lymphoma.

LOW ALBUMIN LEVEL CORRELATES WITH POORER SURVIVAL OF PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA: SERBIAN LYMPHOMA GROUP EXPERIENCE

J. Jelicic[1,*], D. Antic[2], M. Todorovic Balint[2], B. Andjelic[2], O. Markovic[3], I. Petkovic[4], V. Nikolic[5], J. Bila[2], V. Djurasinovic[2], A. Sretenovic[1], V. Vukovic[1], M. Smiljanic[1], B. Mihaljevic[2]
[1]Clinic of Hematology, Clinical Center of Serbia, [2]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, [3]Clinical Hospital Center "Bezanijska Kosa", University of Belgrade, Belgrade, [4]Clinic of Oncology, University Clinical Center Nis, [5]Clinic of Hematology, Clinical Center Nis, Nis, Serbia

Background: Current prognostic scores are not sufficient to define high risk patients with diffuse large B cell lymphoma (DLBCL). Besides parameters included in the International Prognostic Index (IPI), other clinical and laboratory parameters have been investigated as potential prognostic markers. However, contradictory data have been reported.
Aims: The aim of this study was to evaluate prognostic significance of clinical and laboratory parameters on the overall survival (OS) of patients with DLBCL.
Methods: A total of 393 patients (188 females/205 males) with the median age of 60 years (range 18-84) were analyzed. All patients were initially treated with rituximab plus CHOP (Cyclophosphamide, Doxorubicine, Vincristine, Prednisone) or CHOP like protocols.
Results: Ann Arbor stage I, II, III and IV had 56 patients (14.2%), 142 (36.1%), 71 (18.1%) and 124 (31.6%), respectively. Bulky disease had 99 patients (25.2%), B symptoms 263 patients (66.9%), and poor performance status according to the European Cooperative Oncology Group (ECOG) ≥2 had 82 (20.9%). Bone marrow involvement was present in 68 patients (17.3%). Low IPI risk was present in 194 patients (49.4%), low intermediate in 86 (21.9%), high intermediate in 77 (19.6%), and high in 36 (9.2%). Median absolute lymphocyte count (ALC) at diagnosis was $1.35x10^9$/L (range 0.07-60.76x10^9/l), absolute monocyte count (AMC) was 0.64x10^9/l (range 0.06-8.58x10^9/l), ALC/AMC was 2.3 (range 0.07-37.0x10^9/l), hemoglobin level was 125g/l (range 57-421g/l), platelet level was 274x10^9/l (range 50-584x10^9/l), C-reactive protein was 10.2 mg/l (range 0.10-438mg/l), erythrocyte sedimentation rate (ESR) was 30mm/h (range 2-636mm/h), and albumin level was 38g/l (range 20-51g/l).
Complete remission (CR) was achieved in 288 patients (73.3%), partial remission (PR) in 58 (14.8%), stable disease (SD) in 5 (1.3%) and progressive disease in 42 (10.7%). Disease relapse was confirmed in 59/346 patients (17.0%). OS was influenced by the presence of B symptoms (p=0.004, 95% CI 1.263-3.549), ECOG≥2 (p<0.0001, 95% CI, 1.827-4.290), Ann Arbor clinical stage (p<0.0001, 95% CI 1.601-3.883), and albumin level (p<0.0001, 95% CI 0.905-0.953). Optimal cut off point for albumin level was 34g/l, and was determined by Receiver operating characteristic (ROC) curve (AUC 0.699, 95% CI, 0.629-0.770, p<0.0001). The prognostic value of IPI was highly statistically significant for OS (p<0.0001, 95% CI, 1.545-2.236). However, other analyzed parameters did not influence OS. Multivariate analysis among significant parameters (presence of B symptoms, IPI, and albumin), has pointed to IPI (HR 1.81, p<0.0001, 95% CI, 1.489-2.222), and albumin level (HR 1.77, 95% CI, 1.164-2.69, p=0.008) as the most important parameters that influenced survival.
Summary/Conclusions: Although IPI is widely used as a prognostic index in DLBCL, it cannot fully recognize high-risk patients. Pretreatment albumin level may represent a useful tool in order to discriminate high-risk patients and is likely to add significant information to the IPI.

PB1709

TREATMENT PATTERNS AND TREATMENT RESPONSE IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA IN ROUTINE CLINICAL CARE IN THE UNITED STATES – A CLAIMS DATABASE STUDY

A. Galaznik[1,*], J. Bell[1], L. Hamilton[2], A. Ogbonnaya[2], K. Hennenfent[2], M. Eaddy[2], Y. Shou[2]
[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [2]Xcenda LLC, Palm Harbor, United States

Background: DLBCL is the most common histologic subtype of non-Hodgkin lymphoma. Treatment guidelines recommend rituximab in combination with chemotherapy as first-line therapy (1LT). For patients who are refractory or relapse, high-dose chemotherapy with stem cell transplant, combination chemotherapy, or single-agent rituximab are recommended in subsequent lines.
Aims: To compare real-world treatment patterns of patients with newly diagnosed DLBCL to NCCN guideline recommendations.

Methods: The Optum claims database was used to identify adult patients (≥18 years old) with newly diagnosed DLBCL between 01/01/08 and 10/31/15. DLBCL diagnosis was based on ≥1 inpatient claim or ≥2 outpatient claims with DLBCL diagnosis codes, with the index date being the first DLBCL claim. Patients were followed from index date until end of continuous enrollment, death, or end of study period (12/31/15). Treatment patterns and response to treatment were assessed during follow-up. Possible remission was defined as no additional chemotherapy and no supportive care use or receipt of supportive care <30 days after end of line of therapy (LOT) for <30 days. Lack of remission was defined as receipt of supportive care <30 days after end of LOT for >30 days. Progression was defined as initiation of another LOT or evidence of supportive care >30 days after end of a LOT.
Results: Of the 2,216 patients selected into the study, 1,267 (57.2%) initiated 1LT, and median (interquartile range [IQR]) time to therapy was 0.7 (0.4–1.1) months. The majority of patients received combination (87.7%) *vs* single-agent (12.3%) chemotherapy. R-CHOP (60.5%) was the most frequently used combination chemotherapy, while rituximab monotherapy comprised ~67% (8.2%) of single-agent use in 1LT. Median (IQR) duration of 1LT was 4.2 (2.3–4.5) months. At the end of 1LT, 64.0% (n=811) had evidence of remission, 15.0% (n=190) progressed, and 1.2% (n=15) had no evidence of remission. Second-line therapy (2LT) was initiated by 159 patients who progressed after 1LT; 29.6% received a single agent, and 70.4% received combination chemotherapy. In 2LT, rituximab (12.6%) remained the top single agent used, while bendamustine+rituximab (15.7%) and R-CHOP (8.2%) were the most common combinations; 8.2% of patients received stem cell transplant. Median (IQR) duration of 2LT was 2.1 (1.2–3.8) months. Of the 2LT patients, 44.0% (n=70) had evidence of remission, 26.4% (n=42) progressed, and 3.1% (n=5) had no evidence of remission. 34 patients who progressed after 2LT received third-line therapy (3LT); 29.4% received a single agent, while 70.6% received combination chemotherapy. In 3LT, rituximab (5.9%), etoposide (5.9%), and carboplatin (5.9%) were the most common single agents, while bendamustine+rituximab (20.8%) and etoposide+oxaliplatin+rituximab (17.6%) were the most common combinations; 8.8% of patients received stem cell transplant. Median (IQR) duration of 3LT was 3.5 (0.9–5.2) months. Following 3LT, 32.4% (n=11) had evidence of remission, 29.4% (n=10) progressed, and 5.9% (n=2) had no evidence of remission.
Summary/Conclusions: DLBCL treatment in routine clinical care aligns with guidelines, with most patients receiving rituximab in combination with chemotherapy. A small proportion of patients received single-agent chemotherapy in 1LT. As expected, remission rates decreased with subsequent lines of therapy. Some patients were untreated; therefore, subsequent studies should explore reasons for lack of treatment.

PB1710

TP53 GENE MUTATIONS IS A PREDICTOR OF HIGH GRADE B-CELL LYMPHOMA PROGRESSION

A. Misyurina[1,*], V. Misyurin[2], S. Kravchenko[1], A. Kovrigina[1], A. Misyurin[2], E. Baryakh[3], A. Magomedova[1], E. Nesterova[1], E. Pushkova[4], J. Finashutina[2], A. Vorobiev[1]
[1]National Research Center for Hematology, [2]Federal State Institution "Russian Cancer Research Center. NN Blokhin" Russian Ministry of Health, [3] State budget health care institution "City Clinical Hospital №52 Moscow Health Department.", [4]LLC "Genetechnogogy", Moscow, Russian Federation

Background: High grade B-cell lymphoma (HGBL) is subdivided on poor prognosis double-hit (DH) and not otherwise specified (NOS) variant, which appears sometimes with primary refractory behavior. Mutations in *TP53* gene (MUT-TP53) lead to blockage of apoptosis in cells and appearance of additional oncogenic events contributing to tumor progression. Correlation between presence of MUT-TP53 and anti-tumor response in patients with HGBL is unclear.
Aims: To evaluate an effect of MUT-TP53 on survival parameters of patients with high grade B-cell lymphoma.
Methods: Since 2005 to 2017 years in FGBU National Research Center for Hematology Ministry of Health Russian Federation diagnosis of high grade B-cell lymphoma were established in 47 patients: 13 – double hit, 34 – not otherwise specified. We had available biologic samples from 32 pts with HGBL: 11 – double-hit and 21 – NOS HGBL. 19 pts underwent courses of intensive treatment according to BL-M-04 [Efficacy and toxicity of a new short-term high intensive protocol BL-M-04 for adult patients with Burkitt lymphoma. Baryakh E. *et al.* Haematologica. 2011; 96 (S2): 391-392], 11 - R-(DA)-EPOCH, 2-R-CHOP-21 treatment. A median follow-up period was 10,8 (0,6-160,9) months. *MYC*-rearrangement (*MYC*-R) without *BCL2* and/or *BCL6* rearrangement was detected in 7 pts with HGBL. Sanger sequencing of DNA extracted from paraffin embedded tumor tissue were performed to reveal mutations in exons 5-8 of *TP53* gene. To evaluate an effect on overall survival (OS) and on time to disease progression (of TTP) such factors as MUT-TP53, *MYC*-R and DH was conducted univariate analysis (test of Kaplan-Meier method, log-rank test) and multivariate variance and Cox regression analysis (STATISTICA 10).
Results: A significant mutations of *TP53* were detected in 9 pts (c.535C>T 45,6% p.H179Y, c.524G>C 15,6% p.R175P, c.770T>A 32,4% p.L257Q, c.743G>A 75,6% p.R247Q, c.487T>A 25,2% p.Y163N, c.824G>A 75% p.C275Y, c.713G>A 87,7% p.C238Y, c.517G>A 22,4% p.V173M, c.517G>A 22,4% p.V173M). Pts and their relatives hadn't a history of primary multiple tumors. Seven from nine pts with MUT-TP53 had MYC-R (3-double hit, 4-single hit lymphoma). Groups of pts with WT-TP53 and MUT-TP53 were comparable for main clinical characteristics. According to results of univariate analysis, patients with MUT-TP53 had lower duration of overall survival a higher probability of disease progression. Thus, median of overall survival in pts with c MUT-TP53 was 7,0 (3,5 - 40,9) *vs* 30,5 (0,6 - 160,9) months in patients with WT-TP53, (p=0,03). Median time to disease progression in pts with c MUT-TP53 was 3,5 (0,3 - 16,1) *vs* 30,5 (0,6 - 160,9) months in patients with WT-TP53, (p=0,00016). In multivariate analysis, MUT-TP53 was an independent factor of early disease progression in HGBL independently of double-hit status (Figure 1).

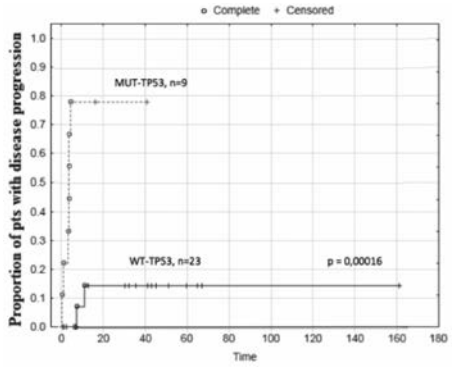

Figure 1.

Summary/Conclusions: Mutations in *TP53* gene - a significant predictive factor of early disease progression in high grade B-cell lymphoma.

PB1711

HTLV-1 INFECTION INCREASED THE RISK OF OTHER MALIGNANCY

A. Nakaya[1,*], S. Fujita[1], A. Satake[1], T. Nakanishi[1], Y. Azuma[1], Y. Tsubokura[1], M. Hotta[1], H. Yoshimura[1], K. Ishii[1], T. Ito[1], S. Nomura[1]
[1]First Department of Internal Medicine, Division of Hematology and Oncology, KANSAI MEDICAL UNIVERSITY, Osaka, Japan

Background: The correlation between HTLV-1 infection and malignant neoplasm other than ATL remains unknown. Some previous studies have indicated that the frequency of primary malignant neoplasms in patients with HTLV-1 seropositive is higher than HTLV-1 seronegative.
Aims: To clarify the correlations between HTLV-1 infection and malignant neoplasms other than ATL.
Methods: We retrospectively analyzed 203 patients with HTLV-1 seropositive who were diagnosed between 2006 and 2015 at Kansai Medical University Hospital.
Results: Among 203 patients (median age 62 years: range 19 to 86 years), 43% was carrier and 57% was diagnosed with ATL. According to clinical subtype, 5% was chronic, 38% was smoldering, 28% was acute, 29% was lymphoma type. Median overall survival was 30 months in carrier, 10 months in acute, 8 months in lymphoma, and smoldering was not available. In all HTLV-1 seropositive patients, the occurrence of primary malignant neoplasm was 32%, they were all carrier or smoldering. Among them, 53% was hematology malignancy (T cell lymphoma; 41%, B cell lymphoma; 29%, MPN; 18%, MDS; 12%). Solid tumor was 47% (lung cancer; 33%, prostate cancer 13%, colon cancer; 13%, renal cell cancer; 13%). Four patients with HTLV-1 carrier who developed primary malignant neoplasm received standard chemotherapy for the neoplasm, and after the chemotherapy they developed 3 acute type and 1 smoldering type ATL.
Summary/Conclusions: In our cohort, the occurrence of primary malignant neoplasm with HTLV-1 seropositive patients was significantly high. Chronic HTLV-1 infection might associate with reduction of cytotoxic T cells and an increased risk of developing other malignancy. Furthermore, cytotoxic chemotherapy for primary malignant neoplasm might reduce cytotoxic T cells for HTLV-1 and exacerbate ATL conditions.

THIOTEPA BUSULFAN CYCLOPHOSPHAMIDE, A TOXIC CONDITIONING FOR AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN CENTRAL NERVOUS SYSTEM LYMPHOMA: REMISSION OR INFECTION?

P.-E. Debureaux[1], B. Royer[1,2], B. Gruson[1], P. Votte[3], M. Joris[1], G.L. Damaj[4], J.-P. Marolleau[1,5], L. Delphine[1,5,*]

[1]Hématologie Clinique, CHU Amiens, Amiens, [2]Hématologie Clinique, Hôpital Saint-Louis, Paris, [3]UPCO, CHU Amiens, Amiens, [4]Hématologie Clinique, CHU Caen, Caen, [5]EA4666, CHU Amiens, Amiens, France

Background: CNSL represent 4% of primary central nervous system (PCNSL) and secondary CNS lymphoma (SCNSL) occur in 7% of systemic lymphoma. Overall survival (OS) and progression free survival (PFS) have dramatically increased in PSNCL since the introduction of Methotrexate high doses and ASCT usually conditioning with TBC (Thiotepa, Busulfan and Cyclophosphamide). The studies usually tend to recommend TBC/ASCT in front line for patients under 65 years with CNSL with very few prospective data about this strategy.
Aims: We report in this multicenter retrospective study our experience concerning TBC/ASCT and its main toxicities.
Methods: All patients treated with TBC/ASCT for PCNSL or SCNSL from August 2010 to November 2016 in our centers were researched by using CHIMIO® software. TBC combined Thiotepa (250mg/m²/d from d-9 to d-7), Busulfan (3.2mg/kg/d from d-6 to d-5 and 1.6mg/kg/d on d-4) and Cyclophosphamide (60mg/kg/d on d-3 and -2) followed by ASCT transplantation at d0. Clinical data were extracted from the medical records. We measured OS and PFS from the date of ASCT and transplant related mortality (TRM) (defined by death occured 3 months after ASCT).
Results: 24 patients, without any major co-morbidity, were included. Median age at ASCT was 58 years (23-66). 22 of 24 were DLBCL and 2 follicular lymphoma and there were 15 PCNSL and 9 SCNSL. All but one, received 1 or 2 lines of chemotherapy (with high doses Methotrexate in first or second line) before ASCT. 15 were in complete response (CR) and 9 in partial response (PR) before TBC/ASCT. Median duration of hospitalisation was 33 days (15-78 d) and of aplasia was 14 days (7-37 d). Median follow-up was 10 months (0-73). At the end of follow up 5 patients have died. Among the 3 patients older than 60 years in PR before ACSCT, no one survived. At 1 year, OS and PFS were respectively 78% and 73%. Surprisingly (Table 1), we noted an important rate of toxicity (100% with 66% ≥grade 3) with a TRM=21%. Neurological adverse events (37%: 9 patients with 4 comas) and infections (100% with 41% ≥grade 3) were predominant. We documented 2 CMV reactivations and 5 fungal infections (3 candida, 1 aspergillus and 1 cryptococcus).

Table 1.

WHO criteria	Grade I-II	Grade III	Grade IV	All

Colitis	18 of 24 (75%)			
Renal dysfunction	2 of 24			
Haemorrhagic cystitis	2 of 24			

We observed 5 deaths (4/5 older than 60 years) in first 3 months due to a septic choc, 4 associated with a persistent coma and 2 with an acute respiratory distress syndrome.
Summary/Conclusions: To our knowledge, here is one of the biggest retrospective cohort concerning TBC/ASCT in CNSL. If TBC seems to give interesting response rates (72% CR), we noted an unacceptable toxicity compared to other used conditionnings (for example TRM with Thiotepa Carmustine is 1%). Our high toxicity rates (66%≥grade 3), especially in elderly patients, with neurological adverse events and infections (with unusual microbiological agents) lead us to disadvise the use of TBC before ASCT.

PB1714

TREATMENT RESULTS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA FROM HIGH RISK AND HIGH-INTERMEDIATE RISK GROUPS

I. Kriachok[1,*], K. Filonenko[2], A. Martynchyk[2], I. Titorenko[2], I. Stepanishyna[2], O. Aleksyk[2], I. Dyagil[3], E. Kushchevyy[2], Z. Martina[3], V. Kozlov[4]
[1]33/43, Lomonosova str., [2]Chemotherapy of hemoblastoses, National Cancer Institute, [3]Radiation hematology, NNCRM, Kyiv, [4]Hematology, Odessky regional hospital, Odessa, Ukraine

Background: Using of Rituximab-containing regimens, as the «gold standard» of treatment of patients with diffuse large B-cell lymphoma (DLBCL), showed significant improvement in the treatment results throughout all prognostic groups. The "real-life" treatment approaches vary depending on financial support of healthcare system in different countries. Unfortunately, treatment results in patients with DLBCL from high and high-intermediate risk groups are still unsatisfying.
Aims: Aim of our study was to compare efficacy and toxicity of different treatment approaches in patients with DLBCL from high risk and high-intermediate risk groups.
Methods: Prospective cohort study was initiated in 2014 in three Ukrainian centers. Patients with newly diagnosed DLBCL and ≥3 risk factors according to International Prognostic Index (IPI) were treated according to "investigators decision" with 6-8 cycles of CHOP-like (first group), R-CHOP (second group) or R-DA-EPOCH regimens (third group). Primary end-point was 2-year progression-free survival (PFS), secondary end-points were 2-year overall survival (OS), overall response rate (ORR), complete response rate (CRR), toxicity rates.
Results: 104 patients were included into analysis in January 2017, 50 males (48,1%), 54 females (51,9%), in the age 23-86 years old, median age 63 years (95% CI 60;65). Observation period was 1-64 months, median – 10.5 months. Patients were divided into three groups according to the treatment regimen. Patients treated with CHOP-like regimens were included into the first group (52 patients, 50.0%). Patients treated with R-CHOP were included into the 2nd group (40 patients, 38.5%) and 12 patients (12.5%) treated with R-DA-EPOCH were included into the 3rd group. Significant difference between the groups was observed by the age (younger patients in the 3rd group, p=0.042) and stages distribution (early stages were more common in the 1st group, p=0.05). ORR was 61.5% in the 1st group, 52.5% in the 2nd group and 83.3% in the 3rd group (p=0.01). CRR was 17.3%, 42.5% and 83.3%, respectively (p<0,001). 2-year PFS was 44,1±9,7% in the 1st group, 74,1±8,8% in the 2nd group and 88,9±10,5% in the 3rd group (p=0,09). 2-year OS was 51,8±8,7%, 54,8±10,2% and 87,5±11,7%, respectively (p=0,197).
The rates of anemia, thrombocytopenia and hepatotoxicity were comparable in three groups. Neutropenia, febrile neutropenia and cardiotoxicity were less common in the group treated with R-DA-EPOCH (p=0.05, p=0.051, p<0,01, respectively). Neurotoxicity was more frequent in this group (p=0.043).
Summary/Conclusions: The level of ORR and CRR was significantly higher in the R-DA-EPOCH group. 2-year PFS was significantly higher in the R-DA-EPOCH group, as well. There was no significant difference in the level of 2-year OS between the groups. Toxicity was acceptable in all groups. Levels of neutropenia, febrile neutropenia and cardiotoxicity were less common and neurotoxicity was more frequent in the R-DA-EPOCH group. Thus, R-DA-EPOCH could be considered as the most efficient treatment regimen in patients with DLBCL from high and high-intermediate risk groups.

PB1715

PROGNOSTIC MODEL WITH NEUTROPHIL-LYMPHOCYTE RATIO AND PERFORMANCE STATUS IN DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH R-CHOP

S.-I. Go[1], G.-W. Lee[1,*]
[1]Internal Medicine, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of

Background: Growing evidences suggest the close relationship between inflammation, host immunity, and tumor cells. The neutrophil to lymphocyte ratio (NLR) has been known to predict the prognosis in patients with diffuse large B-cell lymphoma (DLBCL).
Aims: This study was planned to confirm the prognostic and predictive value of NLR and to make a model to predict the prognosis more precisely in patients with DLBCL.
Methods: Data of 192 DLBCL patients treated with R-CHOP from 2004 to 2016 were retrospectively assessed. Patients with NLR ≥4 and <4 were determined as the high and low NLR groups, respectively. Treatment response and survival were compared according to the NLR status and using the model including NLR and other variable interacting with NLR.
Results: High NLR group was associated with old age, poor performance status (PS), elevated lactate dehydrogenase, and more advanced prognostic indices than low NLR group. High NLR group had a low complete response (CR) rate compared to low NLR group (57.5% *vs* 81.4%, p=0.004). However, the role of NLR as prognostic factor was not demonstrated on multivariate analysis, which showed strong interaction between NLR and PS. The model composed of NLR and PS could stratify the patients into low-, intermediate-, and high-risk groups for overall survival (OS). On multivariate analysis, compared to low risk group, the hazard ratios of intermediate and high risk groups on OS were 1.871 (p=0.019) and 2.733 (p=0.004).
Summary/Conclusions: High NLR is associated with poor treatment response and unfavorable clinical features in DLBCL. The prognostic model using NLR and PS can predict more precisely the prognosis of this population and needs to be validated in the independent cohort.

PB1716

HIGH SERUM LEVELS OF SOLUBLE INTERLEUKIN-2 RECEPTOR ARE ASSOCIATED WITH A POOR PROGNOSIS IN CASES OF RELAPSED/REFRACTORY PERIPHERAL T CELL LYMPHOMA, NOT OTHERWISE SPECIFIED

M. Morita[1,*], D. Katoh[1], A. Tanaka[2], M. Nakamura[1], A. Fujimoto[1], T. Yabushita[1], Y. Shimomura[1], Y. Ono[1], A. Hashimoto[2], N. Hiramoto[1,3], S. Yoshioka[1], N. Yonetani[1], Y. Tanaka[2], A. Matsushita[1], H. Hashimoto[3], I. Sinzato[2], T. Ishikawa[1]
[1]Hematology, Kobe City Medical Center General Hospital, [2]Hematology, Nishikobe medical center, [3]Cell Therapy, Institute of Biomedical Research and Innovation, Kobe, Japan

Background: The prognosis is extremely poor for cases of relapsed/refractory peripheral T cell lymphoma, not otherwise specified (PTCL-NOS), and there

are no established predictors of prognosis. Although serum soluble interleukin-2 receptor (sIL-2R) levels are associated with clinical outcomes in newly diagnosed patients with PTCL-NOS, it remains unclear whether sIL-2R levels can predict prognosis in patients with relapsed/refractory PTCL-NOS.
Aims: This study evaluated whether sIL-2R levels at the time of salvage chemotherapy were associated with prognosis in cases of relapsed/refractory PTCL-NOS.
Methods: We retrospectively analyzed 45 patients with relapsed/refractory PTCL-NOS who received salvage chemotherapy at our institutions (1996–2016). All patients received CHOP or CHOP-like therapy as their initial treatment. The primary outcome was defined as overall survival (OS), which was calculated from the date of the salvage chemotherapy to the date of death from any cause or the last follow-up.
Results: The median age at salvage chemotherapy was 68 years (range: 37–86 years). The median serum sIL-2R level was 3,476 U/mL (range: 280–24,400 U/mL). Receiver operating characteristic curve analysis revealed that the optimal sIL-2R cut-off value for predicting OS was 2,283 U/mL (area under the curve: 0.672, 95% confidence interval [CI]: 0.421–0.923). Thus, we defined patients with serum sIL-2R levels of ≥2,283 U/mL as the high sIL-2R group and the other patients as the low sIL-2R group. The two groups had similar clinical characteristics at the salvage chemotherapy, with the exception of their international prognostic index (secondary IPI) and performance status (PS). The high sIL-2R group had significantly higher secondary IPI (≥H-I) and poorer PS (≥2). Eight patients were alive at the time of the analysis, with a median follow-up of 55 months (range: 2–136 months). The 2-year OS among all patients was 25.1% (95% CI: 13.6–38.5), and the high sIL-2R group had significantly poorer 2-year OS (10.9%, 95% CI: 2.8–25.4 *vs* 50.0%, 95% CI: 24.5–71.0, P <0.001). A multivariate analysis was performed using the following factors: serum sIL-2R levels (high *vs* low), secondary IPI (≥H-I *vs* ????????) (Figure 1).

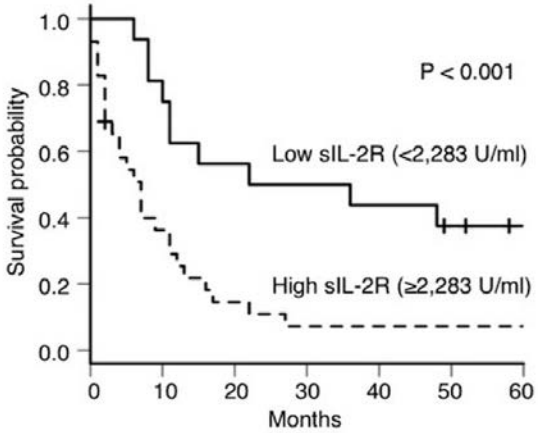

Figure 1. Overall survival according to serum sIL-2R levels.

Summary/Conclusions: Serum sIL-2R levels are a useful predictor of prognosis in cases of relapsed/refractory PTCL-NOS, especially among patients with low secondary IPI risk.

PB1717

AUTOIMMUNE DISEASES ARE NOT ASSOCIATED WITH INFERIOR PROGNOSIS IN LYMPHOMA PATIENTS

Y.-H. Shih[1,*], C.-L. J. Teng[1], H.-C. Lin[1], W.-L. Hwang[1]
[1]Division of Hematology/Oncology. Department of internal medicine, Taichung Veterans General Hospital, Taichung, Taiwan, Republic of China

Background: Previous epidemiological studies have shown that autoimmune diseases increase the risk of lymphoma development. Immune dysregulation could be the possible underlying pathogenesis. Whether autoimmune diseases deteriorate outcome of lymphoma patients, however, remains unclear.
Aims: The objective of this study is to compare the clinical outcome among lymphoma patients with and without autoimmune diseases.
Methods: From January 2008 to November 2016, we retrospectively reviewed medical records of 913 newly diagnosed lymphoma patients. From these 913 lymphoma patients, 34 (3.71%) patients were diagnosed to have autoimmune diseases before their lymphoma identification. Among these 34 patients, six patients lost their follow-up. A total of 28 lymphoma patients with pre-existing autoimmune diseases were finally analyzed. For the further comparison, 56 lymphoma patients without pre-existing autoimmune diseases who were adjusted for age and gender were considered to be the control group. Response rate, progression-free survival (PFS), and overall survival (OS) were compared between these two groups of patients.
Results: Rheumatoid arthritis was the most common autoimmune disease in lymphoma patients (11/34; 32.3%). The complete remission rate for lymphoma patients with and without autoimmune diseases were 72.0% and 83.3%, respectively (p=0.178). The PFS for patients with and without autoimmune diseases were 44.3±32.1 months and 50.9±28.6 months, respectively (mean±standard deviation; p=0.334). These two groups of patients had similar OS time as well (46.4 ±31.5 months *vs* 52.9±28.0; mean±standard deviation; p=0.337). Univariate analysis did not show autoimmune diseases were associated with inferior OS in lymphoma patients (crude hazard ratio: 1.32; 95% confidence interval: 0.43 - 4.07; P=0.627).
Summary/Conclusions: The results of this case-control study showed the autoimmune disease was not a poor prognostic factor for lymphoma patients.

PB1718

THE DIAGNOSTIC AND PROGNOSTIC IMPLICATIONS OF CIRCULATING MIRNA-21 IN A SAMPLE OF HEPATITIS C/NONE HEPATITIS DIFFUSE LARGE B-CELL LYMPHOMA EGYPTIAN PATIENTS

M. Moussa[1,*], N. Elhalawani[1], A. Nazir[1], N. Mashali[2], M. H. Nafea[1], A. Sorour[3]
[1]Hematology, [2]Pathology, [3]Clinical Pathology, Alexandria Main University Hospital, Faculty of Medicine, Alexandria University, Egypt, Alexandria, Egypt

Background: MicroRNAs (miRNAs) are small RNA molecules which control the expression of many target messenger RNAs involved in cell differentiation, proliferation and apoptosis. Circulating microRNAs are potential biomarkers of diagnostic and prognostic impact in various inflammatory and malignant diseases. Unlike all other malignancies, studies of the prognostic implication of miRNA-21 expression in diffuse large B-cell lymphoma (DLBCL) patients have been a matter of debate. To our knowledge, there are no existing data up to date on the expression of miRNA-21 in hepatitis C virus (HCV) associated DLBCL.
Aims: Linking inflammation with malignancy, we studied the expression of miRNA-21 in sera of hepatitis-C-virus and none hepatitis DLBCL patients, aiming to identify its differential expression and prognosis in DLBCL with its subtypes; germinal center B-cell (GCB) and activated B-cell-like (ABC) and to evaluate its relation with HCV.
Methods: MiRNA-21 expression was measured using Taq-Man quantitative RT-PCR in sera of 30 newly diagnosed DLBCL patients (HCV positive (n=10), HCV negative (n=20)) and 20 controls (HCV positive (n=10), HCV negative (n=10)). The diagnosis of DLBCL and its sub-classification in GCB and ABC subtypes were done by applying the criteria of the WHO classification of tumors of the hematopoietic and lymphoid tissues 2008 and revised in 2016 and were confirmed by Immunohistochemistry using antibodies to CD10, BCL-6, MUM-1 and BCL-2. HCV was diagnosed by detection of anti-HCV antibodies in sera of patients and controls by Enzyme-Linked Immunosorbent Assay (ELISA) technique and HCV genetic detection and quantification by polymerase chain reaction (PCR). All the patients received CHOP chemotherapy and were followed up for an average of 24 months.
Results: MiRNA-21 expression was significantly higher in DLBCL patients than in controls (p=0.00). Significant positive correlations between miRNA-21 and LDH, IPI and disease stage were detected (p <0.05). Significantly higher miRNA-21 levels were detected in ABC subtype compared to GCB subtype (p=0.00). Significantly higher miRNA-21 expression levels were detected in BCL6 negative, CD10 negative, MUM1 positive DLBCL cases compared to its levels in BCL6 positive, CD10 positive and MUM1 negative cases, (p=0.018, 0.002 and 0.001 respectively). Higher miRNA-21 was associated with worse response (p=0.016), 2-year overall (p=0.017) and 2-year progression free survival with statistical significance (p= 0.003). Significantly higher miRNA-21 levels were detected in HCV positive DLBCL patients compared to HCV-negative patients (p=0.00). Higher miRNA-21 levels were detected in HCV positive ABC subtype than GCB subtype (p=0.05). Significantly higher levels were also detected in HCV positive controls compared to HCV-negative controls.
Summary/Conclusions: Our study showed that miRNA-21 was overexpressed in DLBCL patients, displaying higher levels in ABC than in GCB subtypes. MiRNA-21 was associated with poor response to treatment and survival in DLBCL. According to our results, miRNA-21 is a potential marker of necro-inflammation independent of its role in tumorigenesis, showing higher expression in HCV positive DLBCL patients compared to none hepatitis patients.

A NEW SCORING SYSTEM FOR PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA – A RETROSPECTIVE MULTI-CENTER ANALYSIS IN TAIWAN

Y.-C. Su[1,2,*], S.-W. Lai[3], C.-C. Lin[4], G.-M. Lai[5], N.-J. Chiang[67], H.-C. Wu[8], Y.-F. Wu[9], C.-C. Chen[10,11], J.-Y. You[12], S.-F. Cho[13], Y. Yang[14], C.-H. Yeh[15], E.-J. Hsueh[16], C.-L. Chang[17], C. G. Chen[18], T.-Y. Chao[1]
[1]Hematology-oncology, Taipei Medical University-Shuang Ho Hospital, New Taipei, [2]Cancer biology and drug development, Taipei Medical University, [3]Hematology-oncology, Tri-Service General Hospital, National Defense Medical Center, Taipei, [4]Hematology-oncology, China Medical University Hospital, Taichung, [5]Hematology-oncology, Changhua Christian Hospital, Changhua, [6]Hematology-oncology, National Cheng Kung University Hospital, [7]National Institute of Cancer Research, National Health Research Institutes, [8]Hematology-oncology, Chi Mei Hospital, Tainan, [9]Hematology-oncology, Buddhist Tzu Chi General Hospital, Hualien, [10]Hematology-oncology, Chang Gung Memorial Hospital, Chiayi, [11]College of Medicine, Chang Gung University, Tao-Yuan,

[12]Hematology-oncology, Lotong Pohai Hospital, Yilan, [13]Hematology-oncology, Kaohsiung Medical University Hospital, Kaohsiung, [14]Hematology-oncology, Taichung Veterans General Hospital, Taichung, [15]Hematology-oncology, Kaohsiung Veterans General Hospital, Kaohsiung, [16]Hematology-oncology, Ping-Tung Christian Hospital, Ping-Tung, [17]Hematology-oncology, Wan Fang Hospital, [18]Hematology-oncology, Mackay Memorial Hospital, Taipei, Taiwan, Republic of China

Background: Primary central nervous system lymphoma (PCNSL) is a rare type of non-Hodgkin's lymphoma. Two independent prognostic scoring systems have been developed at the Memorial Sloan-Kettering Cancer Center (MSKCC) and the International Extranodal Lymphoma Study Group (IELSG). The former considers age and Karnofski's performance status (PS) as prognostic parameters(*JCO.* 2006;24:5711). The latter includes age, Eastern Cooperative Oncology Group (ECOG) PS, the presence of deep lesions, serum lactate dehydrogenase (LDH) and total protein levels in the cerebrospinal fluid (CSF)(*JCO* 2003;21:266). Neither of the two systems has been verified in the Asian population, leading to concerns regarding applicability in this region.
Aims: This study was conducted to test the prognostic power of the 2 systems in PCNSL patients in Taiwan. In addition, we analyzed the parameters of the IELSG system to figure out the most powerful prognostic factors and then established a new scoring system.
Methods: The medical records of patients with tissue-proven PCNSL were retrieved from 15 academic hospitals in Taiwan through January 2002 to December 2011. They were stratified into different groups according to the MSKCC or the IELSG system and the overall survivals (OS) were evaluated. All parameters in the IELSG system were checked by multi-variable analysis to establish a new scoring system.
Results: When the IELSG scoring system was applied, the 2-year OS in low, intermediate and high-risk groups were 78.3%, 43.9% and 37.5% respectively with a crossover in the latter 2 groups (Figure 1A). When the patients were stratified by the MSKCC scoring system, the 2-year OS of class I, II and III were 65%, 68% and 20% (Figure 1B), respectively. We conducted single-variable analysis of the 5 parameters included in the IELSG scoring system and only age and ECOG PS were statistically significant. In the multi-variable analysis, these 2 factors were almost equally weighted. Based on these findings, we re-stratified the patients into 3 groups. Group 1 comprised patients with both age <60 and ECOG PS <2 and Group 3 with both age ≥60 and ECOG PS ≥2. The patients not fulfilling criteria of either Group1 or Group 3 were categorized as Group 2. According to this new scoring system, the median OS of Groups 1, 2 and 3 were 1,573, 548 and 304 days (Figure 1C), respectively, and their OS curves could be nicely distinguished.

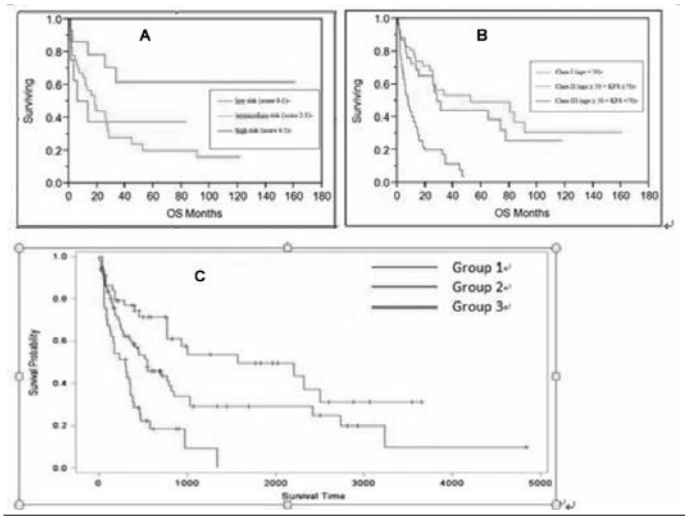

Figure 1.

Summary/Conclusions: Neither the IELSG nor MSKCC scoring system is ideal to distinguish the 2-year OS of the PCNSL patients in Taiwan. The new scoring system comprising age □ 60 years and ECOG PS □ 2 seemed to provide a better prognostic power for Taiwanese patients.

PB1720

RELEVANCE OF CIRS SCALE IN THE PROGNOSIS OF DIFFUSE LARGE B CELL LYMPHOMA IN ELDERLY PATIENTS

C. Plaza-Meneses[1,*], B. Zheng[2], M. Yuste[1], T. Arquero[1], T. Villaescusa[1], E. Askari[1], J. L. Lopez-Lorenzo[1], M.-A. Perez[1], E. Prieto[1], F. Lobo[3], P. Llamas[1], R. Cordoba[1]
[1]Hematology, Hospital Universitario Fundación Jiménez Díaz, [2]University Autonomous Madrid, [3]Oncology, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

Background: The incidence of lymphomas is increasing with age. Many aggressive lymphomas are now considered to be curable. All fit patients, even elders, are candidates for optimal treatment with a curative intent. Diffuse Large B Cell Lymphoma (DLBCL) is the most common non-Hodgkin Lymphoma, with 60% of curative rates after standard R-CHOP regimen. Patients that relapse can be rescued with salvage treatment in 20-30%. The elders are not considered for full standard treatment in many centers. Geriatric scales are starting to being used to stratify patients and offer them individualized treatments. The use of GSCF for neutropenia prophylaxis is not a standard of care in this population.
Aims: The objectives of this study were**:** 1) Validate CIRS score in a DLBCL cohort; 2) Analyse the impact of CIRS score in OS; 3) Analyse the impact of GSCF prophylaxis for neutropenic fever.
Methods: Between November 2008 and November 2015, 41 DLBCL patients with ≥60 years at diagnosis from a single institution and homogeneously treated with R-CHOP were analyzed. Patients were evaluated for comorbidities with Cumulative Illness Rating Scale (CIRS). CIRS score was used to detect the more unfit population and evaluate the average of admissions stay and the impact on OS. The CIRS scale was adjusted by removing the hematological question since all our patients were diagnosed with a hematologic malignancy. The cut-off point for CIRS score was selected using a ROC analysis. Neutropenic fever (NF) events were recorded and the use of GSCF in prophylaxis were analyzed, as well as the admission days for adverse events.
Results: In our series, 20 patients (48%) were males. Median age at diagnosis was 73 years old (range 60-90) With a median follow-up of 32 mo. (range 0-96), the median PFS was 51 months and the OS was 61 mo. The patients were stratified by the R-IPI and the NCCN-IPI. The ROC analysis showed a scoring of 5,5 in CIRS to identify two different risk groups, with an AUC of 70,5%, a sensibility of 87% and a specificity of 48% (p=0,02). In the low risk group, with CIRS <6 (n=17), 7 (41%) patients were admitted with a mean of stay of 6,2 days (range 1-16) *vs* the high-risk group with CIRS >6 (n=24). Of this group, 11(45%) patients were admitted with a mean of stay of 10,6 days (range 1-62), p=0,035. The CIRS scale was also used to discriminate two OS groups; the low risk showed a median OS not reached *vs* 29 mo. the high-risk group, with a Hazard ratio of 2,68 (CI95%: 1,031-5,882, p= 0,042). NF was the most common ER visit, n=18 (36%). Of the 18 patients with NF, 10 (55%) were prescribed with GCSF prophylaxis mid cycles. Of all patients with GCSF (n=43) only 10 (24%) NF were reported. 11/17 patients (65%) who didn't use GCSF prophylaxis had an NF episode. The Odds ratio (OR) for the patients under prophylaxis was 0,232 (CI 95%: 0,085-0,634, p=0,004) (Figure 1).

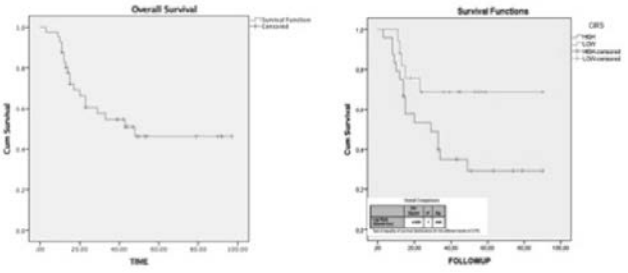

Figure 1.

Summary/Conclusions: The OS and the PFS in our sample is similar as described in larger studies. The days of admissions adjusted to the CIRS scale give us a tool to help physicians to discriminate patients with DLBCL that will have prolonged admissions when treated with the standard of care. The CIRS scale also help separate two distinct OS curves, giving physicians a new tool to help discriminate worse prognostic patients, making them good candidates for adapted therapies. The use of GSCF prophylactic can protect the elderly patients from NF, and should be used in all patients in this category.

PRIMARY ADRENAL LYMPHOMA: A SINGLE-CENTER EXPERIENCE

L. Yuan[1], L. Sun[2], W. Du[3], Y. Zhao[1,*]
[1]Department of Hematology, [2]Department of Pathology, [3]Department of Oncology, Chinese PLA General Hospital, Beijing, China

Background: Primary adrenal lymphoma (PAL) is rare, with slightly more than 250 cases currently described in the English-language literature. In current classifications, there is not yet a consensual definition of PAL.
Aims: The aim of this study was to report a large single-center clinical case series of primary adrenal lymphoma (PAL) in terms of clinical presentation, pathological and imaging features, and treatment outcome.
Methods: We performed a retrospective analysis of 21 patients diagnosed with PAL who presented to our center between January 2005 and January 2014.
Results: Median age at presentation was 48 years (range: 27–73) with a male-to-female ratio of 5:2. Bilateral and right-sided adrenal involvement were seen in 12/21 and 7/21 patients, respectively. Adrenal insufficiency (AI) was seen in

6/10 evaluated patients. Computed tomography scans showed slight to moderate contrast enhancement of adrenal masses in 4/5 patients (80%), and magnetic resonance imaging identified a normal T1 and longer T2 phase. Diffuse large B cell lymphoma (DLBCL) was the most common immunophenotype (85.6%). Two patients died due to rapid disease progression before treatment. Three patients were treated with chemotherapy±external beam radiotherapy. Two patients received autologous stem cell transplantation as consolidation therapy. Five-year overall survival and progression-free survival were 54.2% and 51.0%, respectively.
Summary/Conclusions: These findings suggest that PAL should always be considered in differential diagnosis of adrenal mass with AI. Moreover, DLBCL was observed as the most common histological subtype of PAL. Despite the contrasting previous reports, long-term prognosis of PAL is not necessarily inferior to that of non-Hodgkin lymphoma in general.

PB1722

EFFICACY AND SAFETY OF IBRUTINIB THERAPY IN RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA IN REAL-LIFE – A MULTICENTRIC STUDY (R.E.P. - APULIAN HEMATOLOGY NETWORK)

V.P. Gagliardi[1,*], N. Cascavilla[2], N. Di Renzo[3], A. Melpignano[4], G. Loseto[5], V. Pavone[6], F. Gaudio[1], G. Specchia[1], T. Perrone[1]
[1]Hematology with Transplantation, A.O.U. Policlinico di Bari, Bari, [2]Hematology, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, [3]Hematology, "Vito Fazzi" hospital, Lecce, [4]Hematology, "A. Perrino" hospital, Brindisi, [5]Hematology, IRCCS Istituto Tumori "Giovanni Paolo II", Bari, [6]Hematology, "Cardinale G. Panico" hospital, Tricase, Italy

Background: Mantle cell lymphoma (MCL) is a rare subtype of non-Hodgkin lymphoma that has an aggressive clinical course and poor prognosis. Although current front-line combination chemo-immunotherapies followed by autologous stem-cell transplantation (ASCT) have improved the outcomes of affected patients (pts), this disease is still incurable and relapse is common. Ibrutinib is an oral covalent inhibitor of Bruton tyrosine kinase that showed significant activity in relapsed/refractory MCL in clinical trials, but in real-life routine, the efficacy and safety may not always mirror those seen in clinical trials.
Aims: We investigated the clinical use of ibrutinib as a single-agent in 31 pts with relapsed or refractory MCL to obtain additional information about predictive factors, outcomes and toxicity in a real-life context.
Methods: We studied a group of 31 pts treated (or still in treatment) with ibrutinib to assess effectiveness in terms of overall response rate, complete response rate, progression free survival and adverse events (AEs) in a real-life context. Data were collected also with reference to clinical and biological characteristics of the disease (MIPI, MIPIb, bone marrow involvement, stage, histology, presence of bulky mass and/or extranodal disease) both at the time of diagnosis and at the time of the start of ibrutinib therapy, and to the type and number of previous therapies.
Results: At the start of ibrutinib therapy, the median age was 70 years (range, 45-82), 100% of pts had high risk MCL according to the MIPI score, 83.9% of pts had disease stage III or higher, 41.9% of pts had bone marrow involvement, and 45.2% of pts presented extranodal involvement of MCL. 26 pts were treated for relapsed MCL, 5 for refractory disease. They had received a median of 2 (range, 1-5) prior regimens including different chemo-immunotherapy schemes, ASCT and newer agents such us bortezomib, lenalidomide, temsirolimus. We observed 6 complete responses, 1 after only 2 months of therapy, the others within 6 months of therapy. After 15 months, we observed 4 relapses, characterized by leukemic disease and one of them also presented central nervous system involvement, and 8 progression. 80% of pts treated for refractory disease presented progression within 6 months. The most common AEs were fatigue (13% of pts) and weight increase (13% of pts), followed by diarrhea and bleeding (grade ≤ 2) (6.4% of pts). The most common hematologic event observed was neutropenia (9.7% of pts, grade ≤ 2). With an estimated median follow-up of 6 months (range, 4-29), 19 pts are still receiving treatment, 12 have discontinued therapy for relapse or progression of disease. Follow-up is still ongoing.
Summary/Conclusions: Single-agent oral ibrutinib shows a high response rate and produces rapid responses regardless of the number and quality of prior regimens. However, the quality and time of response does not seem to be predictive of a better PFS or longer duration of response. Furthermore, resistance to ibrutinib in pts with MCL is associated with fulminant, severe progression. Ibrutinib is well tolerated also in real-life experience. The weight increase in 13% of pts suggests that ibrutinib may have an anabolic effect, including alterations in blood pressure and lipid profile. Larger cohorts of pts and longer follow-up are warranted to confirm these preliminary data.

PB1723

HEMATOLOGICAL MALIGNANCIES IN SOLID ORGAN TRANSPLANT RECIPIENTS: RETROSPECTIVE SINGLE-CENTER ANALYSIS IN JAPAN

K. Fujimoto[1,*], I. Daiki[2], R. Goto[3], K. Morita[2], T. Ooka[4], K. Hatanaka[5], H. Goto[1], J. Sugita[1], M. Onozawa[1], D. Hashimoto[1], K. Kahata[1], T. Kondo[1], Y. Matsuno[5], T. Shimamura[6], T. Teshima[1]
[1]Department of Hematology, [2]Department of Urology, [3]Department of Surgery I, [4]Department of Cardiovascular and Thoracic Surgery, Hokkaido University Graduate School of Medicine, [5]Department of Surgical Pathology, [6]Division of Organ Transplantation, Hokkaido University Hospital, Sapporo, Japan

Background: Solid organ transplant recipients have elevated onset risks of hematological malignancies (HMs) due to long-term administration of immunosuppressant. However, few studies about the incidence and impact on survival of HMs following solid organ transplantation have been conducted in Asian countries.
Aims: The aim of this study was to identify the incidence, characteristics, risk factors and prognosis of HMs in solid organ transplant recipients at our institution.
Methods: Clinical data of patients undergoing kidney, liver and heart transplantation in Hokkaido University hospital between 1965 and 2015 were reviewed retrospectively. Kaplan-Meier analysis was performed for the cumulative incidence rates (CI) of HMs, graft survival and patient survival. Patient's characteristics were compared between groups by the student t-test or Kai-square test.
Results: A total of 16 cases of HMs were identified, 9 post-transplant lymphoproliferative disorder (PTLD), 5 acute myeloid leukemia (AML)/myelodysplastic syndrome (MDS), 1 myeloproliferative neoplasm (MPN)) and 1 recurrent non-Hodgkin lymphoma. The CI of PTLD were 1.1%, 1.5% at 5, 10 years in kidney transplant recipients (n=352), 0.92%, 2.6% at 5, 10 years in liver transplant recipients (n=287) and 20% at 1 year heart transplant recipients (n=5), respectively (P<0.0001). AML/MDS and MPN developed only in liver transplant recipients, and CI were 2.3% at 5 and 10 years (P<0.01). There was no difference in background factors other than transplanted organ type between recipients with HMs and without HMs. Patients with EBV-positive PTLD (n=5) were younger (P<0.05) and had less extranodal diseases (P<0.05) compared with EBV-negative PTLD (n=4). All patients with monomorphic PTLD (n= 4) were treated with chemotherapy combined with rituximab and had been in remission. In patients with other PTLD, reduction or withdrawal of immunosuppressant or rituximab alone resulted in stable disease or remission. All AML/MDS but 2 acute promyelocytic leukemia in pediatric patients were chemo-refractory and lethal. 10-year OS were 92% and 100% in kidney and heart transplant recipients. In liver transplant recipients, 10-year OS were 74%, 100% and 50% in patients without disease, with PTLD and with myeloid neoplasm, respectively. Survival in adult liver transplant recipients with myeloid neoplasms was inferior to that without disease (P<0.05). 10-year graft survival rates were 72% and 75% in kidney transplant recipients without disease and with PTLD.
Summary/Conclusions: The incidence of PTLD in solid organ transplant recipients in Japan is comparable to that in Western countries, whereas the incidence of myeloid neoplasms is higher in liver transplant recipients. PTLD dose not have a negative impact on the prognosis of solid organ transplant recipients under appropriate management, while heightened awareness and better clinical approach for myeloid neoplasms following solid organ transplantation are needed.

PB1724

MYC REARRANGEMENT HAS A STRONG PROGNOSTIC IMPACT IN THE FEMALE PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

H. Nitta[1,*], M. Tanaka[1], Y. Ota[2], A. Gotoh[1], N. Komatsu[1]
[1]Hematology, Juntendo University School of Medicine, [2]Pathology, Teikyo University School of Medicine, Tokyo, Japan

Background: Cytogenetic abnormalities of *MYC* are associated with poor prognosis in patients with diffuse large B-cell lymphoma (DLBCL). Rearrangement of *MYC* reportedly occurs in approximately 10% of DLBCL cases. In addition, in various clinical trials of rituximab with standard dosing, female receiving rituximab have had better outcomes than male. However, gender-segregated outcomes of patients with *MYC* rearrangement have not been reported. In addition, the gender segregation of known prognostic factors, such as high international prognostic index (IPI) score, elevated lactate dehydrogenase (LDH) level, poor Eastern Cooperative Oncology Group performance status (PS), advanced stage, and ≥2 extranodal sites, not as yet been fully elucidated.
Aims: The aim of this study was to determine the gender segregation of clinicopathological and genetic prognostic factors, including *MYC* (fluorescence in-situ hybridization: FISH) in patients with DLBCL by analyzing data from consecutive DLBCL patients.
Methods: In order to identify prognostic factors, we analyzed gender segregation from the medical records of patients with DLBCL, including newly diagnosed and transformed, at Juntendo University Hospital from December 2009 to December 2016. We retrospectively analyzed the data of 161 consecutive DLBCL patients (male: 91 patients, female: 70 patients). Patients in this study were treated with R-CHOP or R-CHOP-based regimens with minor modifications. The relationships between overall survival (OS), progression free survival (PFS) and age, LDH level, PS, stage, ≥2 extranodal sites, IPI, cell of origin (COO), BCL2 (immunohistochemistry: IHC), BCL6 (IHC), MYC (IHC), double expressor (MYC and BCL2 expression on IHC), and *MYC* (FISH) were investigated. Univariate and multivariate analyses of estimated risk factors for OS and PFS were performed using the log-rank test and Cox proportional hazard regression analysis.
Results: The median age was 70 years (range: 27–92 years). The median follow-up was 17 months (range: 1–81 months). To adjust the impact of age, LDH level, PS, stage, ≥2 extranodal sites, IPI, COO, BCL2 (IHC), BCL6 (IHC), MYC (IHC), double expressor (IHC), *MYC* (FISH), and other significant factors, uni-

variate analysis was performed for the OS. Elevated LDH level, stage ≥3, PS ≥2, ≥2 extranodal sites, IPI≥3, BCL6 negative (IHC), and *MYC* rearrangement (FISH) were significant factors in the female patients; however, PS ≥2 and IPI≥3 were significant factors in the male patients. Univariate analysis was also performed for PFS. Elevated LDH level, PS ≥2, IPI≥3, BCL6 negative (IHC), and *MYC* rearrangement (FISH) were significant factors in the female patients; however, PS ≥2 was the only significant factor in the male patients. Multivariate analyses were then performed using these factors in the Cox proportional hazard model. *MYC* rearrangement (FISH) [hazard ratio (HR): 9.13, 95% confidence interval (CI): 2.33–35.77, *P*=0.0015], and IPI ≥3 were identified as independent significant prognostic factor for OS in the female patients with DLBCL. Furthermore, *MYC* rearrangement (FISH) (HR: 2.47, 95% CI: 1.87–327.8, *P*=0.01494], and elevated LDH level were identified as independent significant prognostic factor for PFS in the female patients with DLBCL. On the other hand, PS ≥2 was identified as the only significant prognostic factor for OS (HR: 44.27, 95% CI: 6.71–292.2, *P* <0.001), but not for PFS in the male patients with DLBCL. Five out of seven female patients with DLBCL and *MYC* rearrangement died from lymphoma progression. The median OS in the female patients with DLBCL and *MYC* rearrangement was 8.0 months (range: 1–35 months) compared to 21.5 months in those without *MYC* rearrangement (range: 1–79 months, *P*=0.003). On the other hand, in the male patients (n=13) with DLBCL, *MYC* rearrangement was not significantly associated with poor OS (Figure 1).

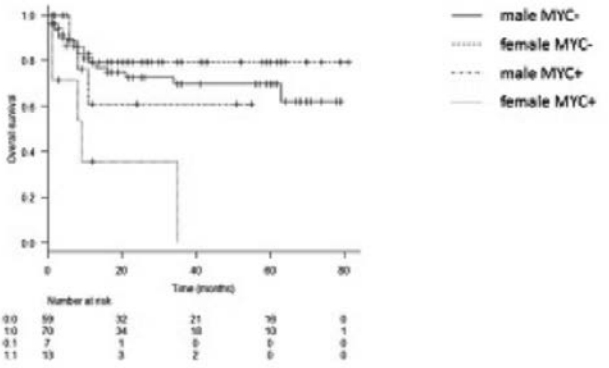

Figure 1. Overall survival.

Summary/Conclusions: These results suggest that *MYC* rearrangement by FISH is significantly associated with very poor OS and PFS in the female patients with DLBCL but not the male patients with DLBCL. On the other hand, PS ≥2 is significantly associated with poor OS in the male patients with DLBCL.

PB1725

ASSESSING THE RISK FOR PERFORATION IN DIFFUSE LARGE B-CELL LYMPHOMA INVOLVING THE INTESTINES USING COMPUTED TOMOGRAPHY CHARACTERISTICS.

N. Sarid[1,*], A. Sherban[1], U. Bendet[1], E. Luttwak[1], Y. Herishanu[1], C. Perry[1], I. Avivi[1]
[1]Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel

Background: Around 40% of all Diffuse Large B-Cell Lymphoma (DLBCL) cases involve extra-nodal sites, the most common being the gastro-intestinal (GI) tract. DLBCL patients with intestinal involvement are particularly prone to develop GI perforation, which might be life threatening and entail significant morbidity. Identification of patients at risk for perforation may promote the performance of pre-emptive surgical resection of the involved segment. Although computed tomography (CT) scan is widely used at diagnosis, incorporation of CT results into the risk stratification of perforation has not yet been performed.
Aims: To determine risk factors for perforation in patients with DLBCL and intestinal involvement, with an emphasis on CT findings.
Methods: A retrospective single center study, including all consecutive DLBCL patients that presented with intestinal involvement between 2005 and 2016. The analysis included clinical, laboratory, pathological and radiological parameters. Cases with DLBCL of the stomach were excluded.
Results: Forty-nine cases (30 men, 19 women) were included. Median age of the entire cohort was 64 years (54.5-77 IQR). Early stage (1, 2) according to the Lugano system was reported in 35% of cases. Small intestine involvement was most frequent (61%), followed by large intestine and ilio-cecum (23 and 16%, respectively). Forty-three (88%) patients underwent CT scan at diagnosis. Most lesions were defined radiology as concentric (n=27, 63%) (as opposed to eccentric), and transmural (n=31, 74%) (as opposed to non-transmural). Of note, 96.3% of the 27 concentric lesions were also transmural, compared with 31% (5/16) of the eccentric lesions. The median length and wall thickness of the involved site were 9.3 cm (5.8-13.5) and 15 mm (10-20), respectively. Ten (20%) patients developed an intestinal perforation. Six of the perforations (60%) involved the small intestine, 3 (33%) occurred at diagnosis prior chemotherapy, and 4 (40%) occurred within the first 21 days post therapy. All perforated lesions were concentric and transmural, with a median length of 11.2 cm. Eight (80%) patients underwent an urgent operation due to GI perforation, including 3 that resulted in an ostomy. Perforation led directly to 2 (20%) deaths. Perforation resulted in delayed administration of chemotherapy in 50% of cases (n=5). A univariate regression analysis found a higher risk of perforation in patients presenting with a concentric lesion (p=0.001. HR=46, CI 31.5-78.5), a transmural lesion (p=0.001. HR=34.6, CI 25.9-53.3) and a longer involved GI segment (p=0.008. HR=1.06, CI 1.017-1.116). Each extra centimeter to the length of the GI segment involved was associated with a 6% increase in the risk for perforation. There was no association between sex, age, performance status, hemoglobin, LDH, albumin, iron, ferritin, KI67, disease stage, anatomical location nor the involved site wall thickness and risk of perforation.
Summary/Conclusions: DLBCL patients presenting with an involvement of a long intestinal segment, especially with a concentric, transmural lesion, are at higher risk for perforation. These patients should be considered for a preemptive surgical resection, dependent on lesion site and operative risk.

PB1726

DOUBLE-HIT AND TRIPLE-HIT LYMPHOMAS: TREATMENT AND CLINICAL OUTCOME IN A SINGLE INSTITUTION

L. Martínez Serra[1,*], E. Gimeno[2], F. García Pallarols[2], I. Vázquez[3], B. Sánchez-González[2], E. Abella[2], C. Pedro[2], A. Ferrer[45], M. Ferraro[2], I. Parraga[1], B. Espinet[5,6], C. Besses[2], L. Colomo[3], A. Salar[2]
[1]Hematology department, Hospital del Mar, [2]Hematology department, Hospital del mar, Barcelona. Grup de recerca aplicada en Hematologia PSMAR, [3]Hematopathology United, [4]Laboratori de citologia hematològica, Servei de Patologia, [5]Grup de Recerca Translacional en Neoplàsies Hematològiques, Programa de Recerca en Càncer, Institut Hospital del Mar d'Investigacions Mèdiques (IMIM), [6]Laboratori de Citogenètica. Servei de Patologia, Hospital del Mar, Barcelona, Spain

Background: Five to 15% of patients with diffuse large B cell lymphoma (DLBCL) present *MYC* and *BCL2* and/or *BCL6* rearrangements which are detected by fluorescence *in situ* hybridization (FISH) or standard cytogenetic. This rearrangement defines a subgroup of DLBCL so-called double hit or triple hit lymphomas (DHL/THL) which are included in the 2016 WHO classification revision of lymphoid neoplasm in a new category "High-grade B-cell lymphoma with rearrangements of *MYC* and *BCL2* and/or *BCL6".* DHL/THL have an aggressive clinical course and poor response to standard chemotherapy and a median overall survival of 0.2-1.5 years. The best therapeutic option in these patients is not yet well established.
Aims: To evaluate retrospectively the incidence, clinical-biological characteristics, type of treatment, overall survival (OS) and progression-free survival (PFS) of patients diagnosed with DHL/THL and to compare them with patients with DLBCL without double/triple-hit genotype (DLBCL-noDH/TH) in a single institution.
Methods: From January 2000 to April 2016, we analized 18 patients with DHL/THL and 312 patients with DLBCL-noDH/TH. DHL/THL cases were identified using FISH for *MYC, BCL2* and *BCL6* in the tumor tissue (11 lymph node biopsy, 2 gastrointestinal biopsy, 1 bone marrow biopsy, 3 skin biopsy and 1 cerebrospinal fluid).
Results: The incidence of DHL/THL was 5.5%. The median age was 70 years [range 53-93]. The patients included in DHL/THL group had a higher prevalence of advanced disease and higher IPI (p=0.002). Thirteen patients received anthracyclines containing chemotherapy, 3 citoreductive treatment and 2 palliative care. No stem cell transplantation was performed in any patient as a consolidation therapy. Four out of 13 patients achieved complete remission, 3 patients partial response and 6 patients were refractory. At last follow up, 13/18 patients were dead (11 lymphoma progression; 2 infectious complications). Median follow-up 63 months. OS in DHL/THL was 9 months and in DLBCL-noDH/TH was not reached (p=0.001). The PFS in DHL/THL and in DLBCL-noDH/TH was 5.4 and 63 months, respectively (p<0.001) (Figure 1).

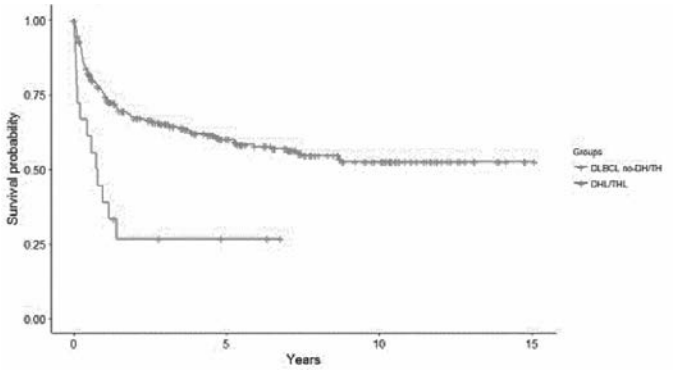

Figure 1. Overall survival.

Summary/Conclusions: 1)The incidence of double or triple hit lymphomas in our institution is consistent with the literature. 2)The most common regimen used in double or triple hit patients was anthracycline-cointaining chemotherapy achieving more than 50% of overall responses in our series. Nevertheless, the majority of patients relapse, showing a short PFS and worse outcome than DLBCL without double or triple hit, as reported previously.

PB1727

EFFECTIVE TREATMENTS ARE REQUIRED FOR PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA WITH PRIMARY REFRACTORY DISEASE

M.Q. Salas[1,*], D.D. Eva[2], M. Santiago[1], O. Ana[1], C. Aguilera[3], E. De la Banda[4], F. Climent[5], N. Garcia Muñóz[1], L. Anna[6], F.D.S. Alberto[1], S.B. Anna[2], G.B. Eva[2]
[1]Hematology, ICO-Duran i Reynals, [2]Hematology, ICO Duran i Reynals, [3]Hematology, ICO-Duran i Reinals, [4]Hematology, [5]Pathological anatomy, Hospital Universitario de Bellvitge, [6]Oncology Radiation Therapy, ICO-Duran i Reynals, Barcelona, Spain

Background: DLBCL is a heterogeneous disease; it has been described that around 30% of patients present a refractory/relapsing disease following R-CHOP treatment. Rituximab-containing salvage chemotherapy followed by high-dose therapy and autologous stem cell transplant (ASCT) in chemosensitive patients remains the standard of care for these patients.
Aims: We aimed to study the clinical features and outcome of patients diagnosed of DLBCL, homogeneously treated with R-CHOP/R-CHOP-like first line regimen, who have primary refractory disease (PRD).
Methods: Three hundred and sixty-seven patients were diagnosed of DLBCL between January 2004 to August 2016 in our center, 317/367 (86,3%) were treated with R-CHOP or R-CHOP-like in first line. Forty-four (13.9%) patients had PRD and 39 (12.3%) progressed during the follow up. Survival curves were estimated using the Kaplan-Meier method and compared using the Log-Rank test. Risk factors at diagnosis for PRD to R-CHOP were assessed. Univariate analyses were performed by Chi square test and multivariate analyses by Cox proportional hazard regression model.
Results: Among the 44 primary refractory patients, 15 (34%), with a median age of 76 years (range 63-91), were considered unfit, 11 received supportive care and 4 were treated with palliative chemotherapy (cyclophosphamide and prednisone). Twenty nine (66%) were eligible for salvage therapy and consolidation with ASCT. Characteristics of those 29 patients at the time of salvage therapy were: median age 50 years (range 21-71), males 19 (65.5%), ECOG 2-4 16 (55.2%), Ann Arbor stage III-IV 23 (79.3%), B-symptoms 9 (31%), bulky disease (20.7%), extranodal involvement 20 (69%), leptomeningeal infiltration 4 (13.8%), high LDH 19 (65.5%), IPI 3-5 21 (72.4%). Salvage therapies used were: R-ESHAP 23 (79.4%), R-ICE 1 (3.5%), MTX-ARAC 4 (13.8%) in patients with leptomeningeal infiltration andintensive burkitt-like therapy 1 (3.4%) in a double hit patient. Twelve (41.4%) did not complete the treatment: 2 (6.8%) for toxicity (1 cardiac event and 1 septic shock) and 10 (34.4%) for progression. The intention-to-treat response rate was: CR 1 (3.5%), PR 4 (13.8%), refractory disease/progression 22 (75.8%) and not evaluable 2 (6.9%). Five patients underwent an ASTC (BEAM as conditioning regimen). One died during transplant due to septic shock and 4 progressed with a median follow-up of 5 months. One patient was rescued with a third line of treatment (R-ICE) and allogeneic transplant, and he is currently in CR at 7 months. Median PFS was 2 months (CI 95% 1.2-2.7) and median OS was 5 months (CI 95% 3.4-6.6). Among the 15 primary refractory patients who were treated with palliative intention, median PFS was 1 month (CI 95% 0.19-1.80) and median OS 1 month (CI 95% 0.19-2.42). Among the 317 patients treated with R-CHOP, risk factors at diagnosis for having PRD to R-CHOP were: B-symptoms (HR 1.94, 95% CI: 1.05-3.61, p=0.034) and elevated LDH (HR 3.92, 95% CI: 1.61-9.51, p=0.003) (Table 1).

Table 1.

Risk factors at diagnosis for primary refractory DLBCL to R-CHOP

	Univariate (χ^2 test)	Multivariate (Cox regression model)		
	P value	HR	CI 95%	*P value*
Gender	0.226	0.55	0.299-1.04	0.067
Aged ≥ 60 years	0.757	1.05	0.567-1.962	0.865
ECOG ≥ 2	0.089	1.45	0.76-2.78	0.256
Ann Arbor stage III-IV	**0.002**	2.04	0.85-4.88	0.107
B-Symptoms	**0.005**	**1.94**	**1.05-3.61**	**0.034**
Bulky mass (>5cm)	0.053	1.67	0.88-3.18	0.116
Extra nodal involvement	0.453	0.71	0.36-1.40	0.326
High LDH	**0.000**	**3.92**	**1.61-9.51**	**0.003**

Summary/Conclusions: Patients with DLBCL refractory to first line R-CHOP are not rescued with current salvage therapies, and in this settingDLBCL must be considered an incurable disease with a very short survival, similar to that of patients treated with palliative care. Patients with B symptoms and elevated LDH at diagnosis have a significant higher risk to be refractory to R-CHOP. It is imperative to identify early these patients and to design new therapies for them.

PB1728

RITUXIMAB BENDAMUSTINE CYTARABINE IS A FEASIBLE AND SAFE INDUCTION REGIMEN PRIOR TO ASCT IN FRONTLINE MCL: A SINGLE CENTER RETROSPECTIVE REAL LIFE EVALUATION

I. Gianesello[1], M. Nabergoj[1,*], A. Branca[1], T. Berno[1], F. Lessi[1], M. Riva[1], E. De March[1], R. Zambello[1], L. Trentin[1], F. Piazza[1], G. Semenzato[1]
[1]Dept of Medicine, Hematology and Clinical Immunology section, University of Padua, Padua, Italy

Background: Mantle cell lymphoma (MCL) is an uncommon, still incurable subtype of non Hodgkin lymphoma. The routine use of high dose Cytarabine and high dose chemotherapy followed by autologous stem cell transplant (ASCT) markedly improved the outcome and has become the standard treatment for fit, young (<65 years) patients. Recently, two phase II studies demonstrated that Rituximab, Bendamustine and Cytarabine (RBAC) combination has a remarkable activity with a favorable safety profile both in untreated and relapsed/refractory elderly MCL patients (Visco *et al.,* 2013 and 2017). These studies suggested that RBAC combination (with Cytarabine 800 mg/mq) is safe and effective as a CD34+ stem-cell mobilizing regimen. No data are available on RBAC with Cytarabine 500 mg/mq as mobilizing regimen in transplant-eligible patients.
Aims: To assess the efficacy and safety of RBAC as induction therapy and as a peripheral blood progenitor cell mobilization therapy in combination with granulocyte colony stimulating factor (Lenograstim) in newly diagnosed transplant-eligible mantle cell lymphoma patients.
Methods: From November 2009 to March 2016, 10 newly diagnosed MCL patients (median age 65 years; range 55-72) were treated as induction immunochemotherapy according to RBAC schedule (Rituximab 375 mg/mq day 1, Bendamustine 70 mg/mq day 2-3, Cytarabine 500 mg/mq day 2-3-4) for 4 cycles. 90% had a stage IV disease; MIPI score was high in one patient (10%), intermediate in 5 patients (50%) and low in 4 patients (40%). Stem cell harvest was performed after 2 cycles. Successful mobilization was defined as achieving physician-determined target PBSC yield which was CD34+ cells >= 2 x 10^6/Kg. The G-CSF (Lenograstim) infusion started per protocol at day 6 at the dose of 5 umg/kg.
Results: All patients completed the scheduled treatment (4 cycles). The ORR was 90%: CR 90% and PD 10% (1 patient). Overall, the rates of successful mobilization and the proportion of patients achieving a total PBSC yield of ≥2x10^6/kg were 100%, and the median PBSC yield was 10 x 10^6/kg (range 3-20x10^6/kg). The median time to stem cell harvest was 17 days (range 14-19). The median number of apheresis to achieve the PBSC target was 1 and only 1 patient (10%) required a second collection procedure. Plerixafor was not used. 80% of patients underwent high dose chemotherapy according to FEAM protocol (Fotemustine 150 mg/mq on days -7, -6, Etoposide 200 mg/mq) and Cytarabine 400 mg/mq on days -5, -4, -3, -2 and Melphalan 140 mg/mq on day -1) with infusion of at least 5 x10^6 /Kg of PBSC. The median day for neutrophils and platelet recovery (ANC >500/mmc, Plts >50,000/mmc) was 11 and 26 (range 10-29 and 14-34), respectively. There was no engraftment failure. Most frequent adverse events (according to CTCAE grading) during therapy were hematological: neutropenia (100%, all 3-4), thrombocytopenia (100%, 60% G3-4), anemia (100%, 50% G3-4). Among non hematological toxicities, 20% of patients had febrile neutropenia (G3-4), 20% mucositis (G1-2), 20% lung infections (G3), 10% hyperglycemia (G3). After a median follow up of 43 months the OS and PFS were 90% and 80% respectively.
Summary/Conclusions: As in the relapsed/refractory setting and in MCL patients ineligible for high dose chemotherapy, RBAC has been proven to be an efficacious induction and mobilization regimen also in transplant eligible MCL patients with an encouraging safety profile. Further investigations are needed to assess the optimal role of RBAC within the standard first line treatments.

PB1729

THE SAFETY OF LIPOSOMAL CYTARABINE IN CENTRAL NERVOUS SYSTEM INFILTRATION BY HAEMATOLOGIC MALIGNANCIES

P. García-Ramírez[1,*], D.P. Millacoy[1], T. Galicia[1], M.C. Mateos[1], J.M. Arguiñano[1], M. Alvarellos[1], M.C. Montoya[1], B. Signes[1], M.L. Antelo[1]
[1]Hematology, Complejo Hospitalario de Navarra, Pamplona, Spain

Background: Central nervous system (CNS) involvement, both leptomeningeal and parenchimatous conveys a poor prognostic in haematological malignancies. As well as systemic chemotherapy that crosses hematoencephalic barrier, intrathecal (IT) chemotherapy has become an attractive approach because of direct action in the cerebrospinal fluid (CSF). Liposomal cytarabine (Depocyte®) is a convenient formulation that maintains cytotoxic concentrations of cytarabine in CSF for an extended period of time (>14 days). This permits to decrease the frequency of lumbar punctures, without losing efficacy and minimizing the patient´s discomfort.

Aims: The objective of this retrospective, observational study is to evaluate the efficacy and safety of liposomal cytarabine in patients with CNS infiltration by haematological malignancies.
Methods: 36 consecutive patients with haematological disease and risk of CNS infiltration underwent flow cytometry (FC) analysis of CSF in a single center from December 2014 to December 2016. CNS involvement was assessed by using standard CSF cytology, 8-color flow cytometry or MRI imaging. Along with systemic therapy, all patients considered positive were treated 50 mg of IT Liposomal cytarabine administered by lumbar puncture every 2 weeks for 4 doses and every 4 weeks thereafter. Concomitant dexamethasone for arachnoiditis prophylaxis was added both i.v. and IT. We analysed the rate of adverse events (AE) and the time for CSF clearance. Short follow up precluded assessment of cumulative incidence of CNS relapse/progression.
Results: Data from 36 patients were analysed. A total of nine patients were considered to have CSF involvement, all of them detected by FC. Of note, all of them were considered negative for CSF infiltration by standard cytology. Three additional patients received IT therapy as prophylaxis since MRI imaging showed brain involvement by the malignancy. The median age of this 12 patients was 52 years (range16-69), 58.3% were female. Diagnosis were B-cell lymphoproliferative disorder 41.7% (CLL, Burkitt, DLBCL), ALL 25%, AML 25% and multiple myeloma 8.3%. The median number of doses per patient was 6.5 (SD 1.7). CSF clearance was achieved after a median of 1 dose (range 1-3) or 20 days (range 16-86). Overall rate of CNS response was 100%. Two patients (16.7%) had leptomenigeal relapse during the IT treatment. The overall AE incidence was 66.7%. The most common AE include: headache, peripheral sensory neuropathy, back pain and nausea. Severe neurotoxicity has been encountered in four patients: cauda equina syndrome (2), encephalitis (1) and arachnoiditis (1). Treatment had to be discontinued in 3 patients because of side effects but this did not lead to relapse. The median time to AE occurrence was 6 cycles (range 4-7) or 110 days (range 33-227). The incidence and severity of AE seemed to increase with the cumulative number of cycles administered. In most patients neurological complications resolved or improved with time.
Summary/Conclusions: use of liposomal formulation of cytarabine for IT administration has become an effective option for the treatment of leptomeningeal involvement by haematological malignancies. Neurological AE are reversible; however, they accumulate and worsen with time, thus precluding long-term use.

PB1730

RETROSPECTIVE ANALYSIS OF OUTCOMES FOR ELDERLY PATIENTS WITH STAGE 3 AND 4 DISEASE HIGH-GRADE DLBCL WITH REDUCED CYCLES OF R-CHOP OR R-GCVP : A 7 YEARS SINGLE-INSTITUTE EXPERIENCE.

K. Joshi[1,*], K. Leung[2], C. Page[2], A. Rajic[3], F. Masieri[4], N. Gill[2], J. Morgan[2], A. Hodson[1], M. Prahladan[1]
[1]Haemato oncology, Ipswich Hospital/ Addenbrookes Hospital, Cambridge, [2]Haemato oncology, Ipswich Hospital, [3]Molecular Biotechnology Unit., University of Suffolk., Ipswich, [4]Molecular Biotechnology Unit., University of Suffolk, Cambridge, United Kingdom

Background: The most common high-grade lymphoid malignancy in adults is Diffuse Large B-Cell Lymphoma (DLBCL), which has an increasing incidence with age (1). Over 40% of patients with DLBCL are above the age of 70, and the co-morbidities in this age-group present significant challenges and complexities with regards to selecting and implementing treatment regimens (2).
Aims: We present a retrospective analysis of outcomes for patients with high-grade DLBCL (stage 3 or 4 disease) who have received fewer than 6 cycles of full dose R-CHOP or R-GCVP because of poor tolerability or disease progression with treatment.
Patients and Methods: Retrospective data were collected from the cancer registry for all newly-diagnosed DLBCL patients who received R-CHOP or R-GCVP chemotherapy, with data collected from Jan 2010 to Feb 2017 from Ipswich Hospital NHS trust, United Kingdom. Patients who completed 6 cycles of chemotherapy were excluded. Interim PET-CT scan/staging CT scan was done to assess the disease response to therapy after 2 cycles of chemotherapy. The main baseline characteristics collected were age, sex, ECOG Performance Status, Ann-Arbor Stage and IPI risk stratification. The primary end point was progression-free survival (PFS) from completion of treatment. Secondary end points were overall response rate (ORR), overall survival (OS), and the reasons for premature ceasing of treatment based on graded toxicity according to NCI-CTCAE 4.0.
Results: Out of 87 patients, 12 patients were identified that fulfilled the inclusion criteria. The median age of patients was 72 years (range: 64-88 years), sex distribution was 7 male: 5 female, ECOG PS was 0-2 in 10 (83%) and ≥3 in 2 (17%) of the patients, Ann-Arbor Stage was 3 in 6 patients (50%) and 4 in 6 patients (50%), and IPI score was 3 in all 12 patients. 11 patients received R-CHOP and 1 patient received R-GCVP. The median length of treatment was 3.5 cycles (range: 1-5 cycles). The overall response rate was 50% on interim assessment and 75% at end of treatment assessment scan. The complete and partial response rates at the end of the treatment were 58% and 17% respectively. Progression free survival was 73% at 2 years (8 out of 11 patients) and 50% at 3 years (4 out of 8 patients). The median overall survival of deceased patients (4 out of 12) was 9.5 months (range: 2-42 months) and the median overall survival of living patients (8 out of 12) is at 40.5 months (range: 27-84 months). The most common reasons for stopping the treatment were intolerance of side-effects (4 out of 12) or neutropenic sepsis (3 out of 12). 2 out of 12 patients received an incomplete course of chemotherapy due to non-response or progression of disease with treatment.
Conclusions: DLBCL treated with less than 6 cycles of full dose R-CHOP or R-GCVP chemotherapy may achieve sustained long-term remission in selected patients with high IPI and significant co-morbidity. Further research on disease characteristics including molecular profile is needed to elucidate selected populations who may achieve long-term remission with shorter cycles of chemotherapy. Further insights may derive, for example, from analysis of polymorphism of folate pathway genes and /or of NF-kB,which have been previously suggested as pharmaco-genomic targets in lymphoid neoplasm. A risk stratification model needs to be developed to reduce drug toxicity and other short and long term treatment related complications so as to improve patient experience, and pharmaco-economic benefits.

PB1731

MULTIPLE NEOPLASMS CONSIST OF SOLID CANCER AND NON-HODGKIN LYMPHOMA

K. Natori[1,*], D. Nagase[1], S. Ishihara[1], A. Shibuya[1], Y. Mitsui[1], Y. Kuraishi[1], H. Izumi[1]
[1]hematology and Oncology, Toho University Medical Center, Oota city, Japan

Background: Malignant lymphoma is a nineth cause of death in Japan. And non-Hodgkin lymphoma(NHL) occupied more than 90%. We experienced cases and will report that we reviewed multiple neoplasms consisting non-Hodgkin lymphoma. We experienced 176 cases.
Aims: We aimed for epidemiology and prognosis improvement of malignant neoplasms including NHL. We want to look for a hint of the early detection.
Methods: We intended for multiple neoplasms 340 cases including hematological malignancy. We reviewed 190 cases of multiple neoplasms including malignant lymphoma. In 190 cases, NHL case were 176 cases. The examination factors are type of the hematological malignancy, gender, the age at onset of the first cancer, interval with the second cancer, treatment strategy. The definition of multiple neoplasms followed Warren & Gates theory. And as for the definition of synchronous type, a diagnosis interval is less than 6 months, metachronous type interval is more than 6 months. About statistical examination, we used SPSS statistics ver21.
Results: All cases are 176 cases, consist of male 108 cases, female 68 cases, synchronous type 45 cases, metachronous type 131 cases. Double neoplasms 149 cases, triple neoplasms 25 cases, quadple neoplasms 2 cases. The median age was 71yrs (ranged51-93yrs), the synchronous type 70yrs(ranged 51-88years), the metachronous type was 73yrs(ranged 57-93yrs). The counterpart of malignancies, Hodgkin's lymphoma 1 case, myelodysplastic syndrome 3 cases, acute myeloid leukemia 8 cases, multiple myeloma 4 cases, gastric cancer 38 cases, colon cancer 32 cases, lung cancer 26 cases, renal cell carcinoma 6 cases, prostate cancer 12 cases, breast cancer 14 cases, urinal bladder cancer 5 cases, uterin cancer 7 cases, esophangeal cancer 9 cases, hepatocellar carcinoma 12 cases. In double neoplasms was 149 cases, metachronous type was 112 cases. The median age of first diagnosis, 68yrs (ranged43-85yrs), the second cancer were 74yrs (ranged57-89yrs), About interval between solid cancer and NHL, median interval time was 58M, solid cancer precedence case was 53 cases, interval was 81M (ranged 7-564M), hematological malignancy precedence case was 59 cases interval was 55M (ranged 8-364M). The cause of death was that 15 cases were solid cancer, 72 cases were hematological malignancy and 6 cases were accident. The median overall survival was 18M(ranged 1-211M), synchronous type 14M(ranged 2-132M), metachronous type 22M (ranged1-116M).
Summary/Conclusions: In the case of a double cancer including solid cancer and NHL, the first cancer occurs in elderly. Diagnosis of malignant neoplasms within 3 years were 48 cases out of 149 cases(32.2%). The important point is that 3 years are required for careful observation at the time of malignancy diagnosis. It is nessessary to discover at the early stage. So it could be a lot of treatment options formalignant neoplasms. We think that a prognosis is improved.

PB1732

RETROSPECTIVE EVALUATION ON EFFICACY AND FEASIBILITY OF R-CODOX-M/IVAC REGIMEN IN AGGRESSIVE DLBCL

E. Coviello[1,*], P. Minetto[1], F. Guolo[1], D. Guardo[1], M. Gambella[1], F. Ballerini[1], R. M. Lemoli[1], M. Gobbi[1]
[1]Haematology, IRCCS San Martino, Genova, Genova, Italy

Background: Diffuse Large B Cell Lymphoma (DLBCL) is an heterogeneous group of diseases. The aggressive behavior can be predicted by clinical risk scores, immunohistochemistry and cytogenetic. Among DLBCL, double hit lym-

phomas (DHL) and double or triple-protein-expression lymphomas (DPLs, TPLs) display a worse outcome. R-CHOP, which is the frontline treatment for DLBCL, showed a poor outcome in high risk IPI patients and DHLs or DPLs. From January 2011 in our centre (IRCCS AOU San Martino Hospital–IST, Genoa, Italy) R-CODOX-M/IVAC regimen has been adopted as first line in patients with aggressive DLBCL, defined by at least one among these features: high tumour burden, DPLs, IPI score >3 or by the presence of at least 1 extranodal site.

Aims: Our aim was to define the efficacy and feasibility of this frontline strategy and eventually identify the subgroups of patients who may benefit from this approach.

Methods: We retrospectively analyzed 20 patients affected by aggressive DLBCL treated with R-CODOX-M/IVAC. R-CODOX-M consists of rituximab 375 mg/sqm day 1, cyclophosphamide 800 mg/sqm day 1, 200 mg day 2-5, doxorubicin 40 mg/sqm day 1, vincristine 1,4 mg/sqm, methotrexate 6700 mg/sqm. IVAC-R contains rituximab 375 mg/sqm, iphosphamide 1500 mg/sqm day 1-5, etoposide 60 mg/sqm day 1-5, cytarabine 2000 mg/sqm bid day 1-2. In both cycles CNS prophylaxis was administered. According to Ann Arbor classification, 11 patients were on stage IV, 1 on stage III, 3 in stage II and 5 in stage I. Twelve patients had B symptoms. Median IPI score was 3. Eleven patients had DPLs and 4 of them had TPLs. Overall survival (OS) was calculated from the time of diagnosis to the dime of death or last follow-up.

Results: After a median follow-up of 28 months, 5 patients died (25%), OS at six and twelve months was 89,4 and 70,4%, respectively, median not reached (NR). Complete remission was achieved in 11 patients (69%), partial remission in 2 patients (13%). The overall response rate was 82%. Three patients (18%) were primary refractory. Among DPLs, OS at six and twelve months was 88,9 and 64,8%, respectively, not significantly lower than non DPLs patients (p=n.s., median NR). In patients with Ann Arbour stage III or IV, OS at six and twelve months was 90,9 and 60,6% (median NR). In patients with IPI score >3, OS at six and twelve months was 78,8 and 45% (median 12 months). The main toxicity during CODOX-M was grade >2 mucositis, 63% of patients. Infections occurred in 71% of patients. Renal and liver toxicity was mainly of low grade and was observed respectively in 38% and 50% of patients. Median severe neutropenia was 4,5 days (range 0-16) and median severe thrombocytopenia was only 1 day (range 0-21). Most patients (56%) needed transfusion support. In IVAC regimen the main toxicity was the haematological one with 7 days of median duration of severe neutropenia (range 3-10), and 7 days (range 6-23) of thrombocytopenia. Seventy-five patients required transfusion support. Infections occurred in 42% of patients. We observed few case of grade >2 mucositis (17%), renal toxicity (8%) and liver toxicity (17%).

Summary/Conclusions: R-CODOX-M/IVAC is a generally well tolerated regimen, with acceptable toxicity profile in the setting of aggressive DLBCL. Results in our cohort suggest a potential benefit for DPLs, whereas higher IPI scores retains a negative prognostic impact. The next step of the study will be retrospective FISH evaluation of C-MYC, BCL2 and BCL6 translocations, for lacking patients in our cohort, in order to disclose a potential benefit for double or triple hit lymphomas.

PB1733

OLDER PATIENTS WITH DLCLB- BODY MASS INDEX AS A PREDICTOR OF SURVIVAL

M. Purić[1,*], N. Milanović[1], D. Gavrilović[2]
[1]Department of Hematology, [2]Department of Statistics, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia

Background: There are contradictory results of earlier studies regarding the impact of body mass index (BMI) on overall survival (OS) or progression-free survival (PFS) of diffuse large B cell lymphoma (DLCLB). Many factors like drug distribution and drug metabolism might influence the outcome in patients with excess body weight. The best method to predict outcome and adjust therapeutic approach is not known and elderly DLCLB patients do not always receive the appropriate therapeutic regimen.

Aims: To evaluate if BMI at diagnosis can predict clinical outcome in older patients with DLCLB receiving the first– line chemotherapy.

Methods: Patients at the Institution for Oncology and radiology of Serbia between 2005 and 2015 who were diagnosed and received first-line chemotherapy for DLCLB, older than 65 years were enrolled. Clinical and treatment data were recorded including BMI at the diagnosis. Patients were stratified into BMI groups according to WHO guidelines: underweight (BMI<18.5kg/m^2), normal weight (BMI 18.5 to<25kg/m^2), overweight (BMI 25 to<30kg/m^2), obesity class I (BMI 30 to<35kg/m^2). Survival time was estimated using the Kaplan- Meier (KM) method, and Cox proportional hazard model was used to evaluate the risk factors significance for survival. A p-value <0.05 was considered significant.

Results: 87 patients were included in the study. 23 (26.44%) patients were older than 75 years, 52 (59.77%) were female, 38 (43.67%) were Ann Arbor stage 1 and 2, 28 (32.18%) were International prognostic index (IPI) score 0-1. The majority of patients were diagnosed as normal weigth (39.08%) and overweight (31.03%), less were in obesity class I group (14.94%) and only 2,3% underweight. 38 (43.68%) patients received CHOP, 27 (31.03%) mCHOP, 12 (13.79%) CVP and 10 (11.49%) CEOP regimen, with or without Rituximab. In the whole group, obese patients had shorter OS and PFS. After a median follow-up of 43 months (range, 1-128), median OS times were 19 months (4-not reached) for obese, 54 months (not reached) for underweight, 90 months (53-not reached) for normal weight and not reached for overweight. PFS was 18 months (4-not reached) for obese, 67 (51-not reached) and 91 months (53-not reached) for overweight and normal weight. In the treatment of normal weight and overweight patients, the same chronological age, frequently was used anthracyclin based regimen (CHOP, 27 patients; mCHOP, 22 patients; CVP, 7 patients; CEOP, 7 patients). There was no difference in the frequency of different regimens in obesity group. In the group of patients treated with anthracyclin based regimens, obese patients tended to have shorter survival, the median OS was 33 months (9-not reached), while normal weight patients tended to have a longer OS, the median OS-not reached. The worse survival among non-anthracyclin regimen treated patients, had obese patients, median OS 26 months (9-not reached). Overweight females and men with normal weight exhibited the best median OS and PFS (not reached). In obese patients, females tended to have a longer OS and PFS (median OS/PFS 19/18 months for women *versus* 9/9 months for men), although the difference was not statistically significant (p=0.77).

Summary/Conclusions: Obesity was associated with shorter survival among older patients with DLCLB treated with different chemotherapy regimens. The impact of gender on PFS and OS varied with BMI. The use of anthracyclin did not influence the outcome of obese patients. This study suggests that BMI may predict survival in older patients with newly diagnosed DLCLB.

PB1734

STOMACH DIFFUSE LARGE B-CELL LYMPHOMA: A SINGLE CENTER EXPERIENCE

M.-T. Sung[1,*], L.-W. Chiou[1], S.-N. Huang[2], A.-C. Feng[2], M.-C. Wu[1], P.-Y. Chen[1], C. Hsiao-Hsiang [1], T.-D. Tan[1]
[1]Department of Hematology and Medical Oncology, [2]Office of Epidemiology and Biostatistics, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, Republic of China

Background: Primary gastric diffuse large B cell lymphoma is a relative rare type of diffuse large B cell lymphoma. Immunochemotherapy followed by consolidation radiation is the mainstay of treatment. However, the cycles of chemotherapy and the role of consolidation radiation are still under debate.

Aims: To review and analyze the treatment experience of newly diagnosed primary gastric diffuse large B cell lymphoma. We presented the treatment outcome of our institution.

Methods: We retrospectively reviewed medical records from Jan 2005 to Dec 2014 from our institution. 30 patients with primary gastric diffuse large B cell lymphoma were included. Clinical characteristics, treatment regimens, treatment response, treatment modality, and survival were analyzed.

Results: From Jan 2005 to Dec 2014, there were 30 patients with primary gastric diffuse large B cell lymphoma. Median age was 65 years of age. 53%(n=16) of patients were male. All 30 patients (100%) have received chemotherapy. 13 of them (43%) have received involved field radiation therapy(IFRT). RCHOP or RCEOP was administered in 86%(n=26) of patients. Complete response(CR) rate was 80%(n=24). 5-year survival was 69%. In patients who achieved complete response(n=24), 5-year survival for 4 cycles of chemotherapy *vs* 6 cycles of chemotherapy were 88% *vs* 86%(p=0.42), respectively. For addition of IFRT in CR patients, 5-year survival for IFRT *vs* no IFRT were 83% *vs* 90%(p=0.93), respectively. Treatment-related mortality(TRM) was 10%(n=3) and primary refractory disease was 10%(n=3). All of them are non-CR patients. Gastrointestinal bleeding which required admission occurred in 10%(n=3) of patients. In patients who developed GI bleeding, 2 of them were non-CR patients and they all died. No patient died of disease relapse after complete response.

Summary/Conclusions: In our series, the 5-year survival was good. In patients who achieved CR, cycles of chemotherapy and consolidation radiation did not make significant difference to the survival. Prevention of early mortality may improve the outcome of this disease. Gastrointestinal bleeding in treatment is rare but with high mortality.

PB1735

IMMUNOHISTOCHEMISTRY BIOMARKERS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: A RETROSPECTIVE STUDY

T. Mendes[1,*], F. Mousinho[1], P. Sousa E Santos[1], E. Viegas[2], A. P. Gomes[1], F. Falcão[2], F. Lima[1]
[1]Clinical Hematology, [2]Pharmacy Department, Phaculty of Pharmacy, Centro Hospitalar de Lisboa Ocidenal; Phaculty of Pharmacy,University of Lisbon, Hospital de São Francisco Xavier, Centro Hospitalar de Lisboa Ocidental, Lisboa, Portugal

Background: Diffuse Large B-Cell Lymphoma (DLBCL) is a heterogeneous disease with variable clinical course. The International Prognostic Index (IPI) is the most important tool to identify subgroups with different survival, however, certain biological markers seem to have a prognostic value relevant and independent of IPI.

Aims: To analyze the evolution of patients diagnosed with DLBCL and the expression of BCL2, BCL6 and MYC.
Methods: We conducted a retrospective study that included hospitalized patients with *de novo* CD20+ DLBCL, with expression of BCL2+, BCL6+, BCL2/BCL6, MYC/BCL2, MYC/BCL6 treated with regimens containing rituximab, from February 2012 to November 2016. Samples were analyzed by immunohistochemistry. Statistical analysis with the SPSS V17.0 program.
Results: We included 43 patients with a median age of 65 years (22-87), 59.5% male, 45,2% had IPI 0-2, 54,8% had IPI 3-5, 26,2% stage I-II, 73,8% stage III-IV, 61,9% had extranodal disease and 23,8% bulky disease. Ki-67 was elevated in all patients who did this evaluation (n=28). In 13 patients was identified BCL2+, BCL6+ in 6, and 21 patients had co-expression of BCL2/BCL6, 1 patient had MYC/BCL2 and 1 had MYC/BCL6. The R-CHOP regimen was first line treatment in 92,8% of patients. The ORR was 82,5%, with 65% of CR, 15% PR and 17,5% PD. Of those patients who received second line treatment, 8 expressed BCL2/BCL6, 4 BCL2, 2 BCL6, 1 MYC/BCL2, and 1 MYC/BCL6. Of the 5 patients who had third line treatment 3 expressed BCL2/BCL6, 1 BCL2, and 1 MYC/BCL6. The average time to next treatment (TNT) was 5,2 months (0,5-19) for second line and 4,9 for third line. Mortality rate was 45,2%. With a median follow up of 18,6 months (3-58,6), the overall survival was 24,6 months (3-62).
Summary/Conclusions: The identification of biomarkers by immunohistochemistry is a relatively inexpensive process, which, when well elaborated and interpreted, allows to find in a safe way, subgroups of patients at high risk, who benefit from more aggressive 1st line therapy and, whenever possible, from the Inclusion in clinical trials with new drugs.

PB1736

INVESTIGATION ON TREATMENT STRATEGY, PROGNOSTIC FACTORS, AND RISK FACTORS FOR EARLY DEATH IN ELDERLY TAIWANESE PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

S.-F. Cho[1,*], Y.-C. Liu[1], H.-H. Hsiao[1], Y.-F. Tsai[1], H.-C. Wang[1], T.-C. Liu[1]
[1]Division of Hematology and Oncology, Department of Internal Medicine, Kaohsiung Medical University Hospital,Kaohsiung city, Taiwan, Kaohsiung city, Taiwan, Republic of China

Background: Given that the population of elderly cancer patients, including those with diffuse large B-cell lymphoma(DLBCL), is increasing, the management of cancer in the elderly has emerged as an increasingly common problem.
Aims: This study aimed to investigate the treatment strategy, prognostic factors, and risk factors of early death in elderly patients (age ≥65 years) with DLBCL in the rituximab era.
Methods: Elderly patients diagnosed with DLBCL between 2008 and 2014 were enrolled for analysis.
Results: There were 145 elderly patients with DLBCL diagnosed between 2008 and 2014. After excluding patients with primary central nervous system DLBCL (n=9) and incomplete data (n=3), a total of 133 patients (64 male and 69 female) with a median age of 74 years (range 65 to 94 years) were enrolled in the present study. Patients at a younger age and with better performance status were more likely to receive intensive frontline treatment. The median progression-free survival (PFS) and overall survival were 15 and 21 months, respectively. Anthracycline-containing chemotherapy achieved a higher remission rate and showed a trend toward better overall survival at the expense of a higher risk of severe neutropenia. Multivariate analysis revealed that very old age (≥81 years), a high-risk age-adjusted international prognostic index (aaIPI) score, and bone marrow involvement were associated with poorer PFS and overall survival. Progression of lymphoma was the major cause of death in the study population. In addition, approximately 25% of patients died within 120 days of their diagnosis. The risk factors for early mortality included very old age, a high-risk aaIPI score, and bone marrow involvement. The appearance of symptoms or signs of tumor lysis syndrome at diagnosis was associated with a trend toward early death.
Summary/Conclusions: Treatment of elderly patients with DLBCL remains a challenge in clinical practice, and comprehensive evaluation to tailor therapeutic interventions and offer the best supportive care may reduce complications and improve the clinical outcome of these patients.

PB1737

TREATMENT OUTCOME OF MONOMORPHIC EPITHELIOTROPIC INTESTINAL T-CELL LYMPHOMA: EXPERIENCE FROM AN ASIAN CANCER CENTER

M.-T. Sung[1,*], M.-Y. Lee[2], M.-C. Wu[1], T.-D. Tan[1]
[1]Department of Hematology and Medical Oncology, [2]Department of Pathology and Laboratory Medicine, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, Republic of China

Background: Monomorphic epitheliotropic intestinal T-cell lymphoma (MEITL), previously type II enteropathy-associated T-cell lymphoma(EATL), primarily occurred in Asian countries. It is refractory to chemotherapy and the prognosis is poor. Intensive chemotherapy has been proposed to improve treatment outcome.
Aims: We examined the treatment outcome of MEITL in our institution.
Methods: We retrospectively searched our institutional database from 1996 to 2014 for intestinal T-cell lymphoma. Medical records were reviewed and the patients were classified on the basis of WHO-2016 classification. Patient's characteristics, treatment modalities, response and survival were collected and analyzed.
Results: Ten patients with intestinal T-cell lymphoma were identified. One patient had enteropathy-associated T-cell lymphoma (EATL) presenting with celiac sprue. Five patients had intestinal T-cell lymphoma, NOS. Four patients were diagnosed with monomorphic epitheliotropic intestinal T-cell lymphoma (MEITL). For patients with MEITL, median overall survival was 7.9 months (4.2-15.0 months). Median age was 46 years of age. Bowel perforation was the initial presentation in 3 patients (3/4, 75%). One patient was treated with chemotherapy with CHOP regimen, while another patient underwent surgery alone. The remaining two patients (2/4, 50%) received surgery followed by chemotherapy (one with CHOP, the other with BFM-90 protocol). Only one patient (1/4, 25%) entered complete response. Of concern, the unique patient achieved complete response received surgery followed by chemotherapy with Berlin-Frankfurt-Munster(BFM)-90 protocol. Remission duration was 10.3 months. He passed away 15.0 months after remission because of relapsed lymphoma.
Summary/Conclusions: Though the prognosis of MEITL is poor, operation followed by high dose chemotherapy such as BFM-90 protocol may have better treatment response, response duration and survival. It deserves further investigation.

PB1738

OSTEOPONTIN AS PRONOSTIC FACTOR OF DIFFUSE LARGE B-CELL LYMPHOMA

G.I. Barranco Lampón[1,2,*], E.B. Ruiz García[2], E.A. Fernández Figueroa[2,3], M.S. Rivas Vera[1], C. Lome Maldonado[4], R. Quezada López[4], E. Cortés[4], J.L. Aguilar Ponce[5]
[1]Hematology, [2]Translational Medicine, Instituto Nacional de Cancerología, [3]Facultad de Medicina, Universidad Nacional Autónoma de México, [4]Pathology, [5]Internal Medicine, Instituto Nacional de Cancerología, Ciudad de México, Mexico

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common type of lymphoma. It is a heterogeneous disease whose prognosis depends on the histological subtype (centralgerminal, non-centrogerminal), as well as other factors such as age, clinical stage, extranodal disease, ECOG scale and levels of lactate dehydrogenase (LDH) identified by established scales (IPI, NCCN-IPI). Osteopontin (OPN) a protein that is secreted by various cells and fulfills physiological functions, when produced by neoplastic cells favors tumor growth and metastasis. This has been corroborated in different types of cancer and there are few reports of cases of patients with DLBCL in which the tumor cell expresses osteopontin, characteristically these cases have presented an aggressive clinical behavior with extranodal disease.
Aims: To evaluate the expression of osteopontin in neoplastic lymphocytes and their association with overall survival; the percentage of patients who expressed osteopontin at diagnosis; the association between the expression of osteopontin and the histological subtype (germinal center, not centrogerminal, unclassifiable); the association between osteopontin expression and age, elevation of DHL, ECOG scale, clinical stage, extranodal invasion and the application of the IPI and NCCN-IPI scales.
Methods: Tissue samples were obtained from DLBCL patients diagnosed at the Instituto Nacional de Cancerología between December 2014 and January 2016. Morphologic and immunochemistry features were studied on paraffin-embedded tissue microarray (TMA). Single antibody staining was performed for OPN. OPN expression was semiquantitatively assessed by three different pathologists scoring the proportion and intensity of stained cells. Positive cases were those that showed any degree of expression in the nucleus or cytoplasm of the tumor cell. Age, ECOG, clinical stage, LDH, extranodal invasion, histological subtype, IPI and NCCN-IPI score were independently documented. Overall survival (OS) analysis was performed by the Kaplan-Meier method, the comparison between different curves was performed using the log-rank test; for the analysis of the relationship between variables we used the X^2 test with a statistical significance of $p < 0.05$.
Results: 81 patients were evaluable. 43.2% of the cases were positive for OPN in neoplastic cells. The mean survival of patients with positive OPN was 14.8 months *versus* 16.5 months for patients with no OPN expression (p=0.628). OPN positivity was not significantly associated with increased age, impaired functional status (ECOG 2,3,4), advanced clinical stage (III, IV), increased LDH or extranodal invasion (including central nervous system); neither was it associated with a specific histological subtype. Survival significantly decreased in patients with increased LDH (p=0.000137), ECOG 2,3,4 (p=1,7374E-7). Survival decreased significantly as the risk measured by the IPI and NCCN-IPI scales increased (p=0.000001, p=0.000013 respectively) with an average survival of 18.6 months for the low-risk group, compared with 6.4 months for the high-risk group (Figure 1).

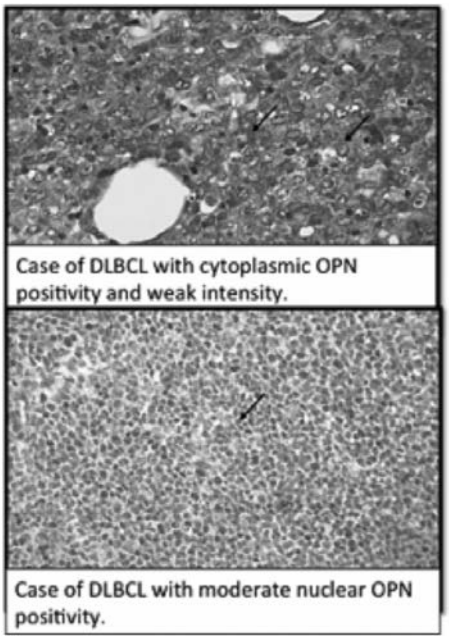

Figure 1.

Summary/Conclusions: Our findings demonstrate that approximately half of the cases evaluated express OPN at diagnosis and tend to have a lower survival rate, however, a longer follow-up time is needed, as well as other studies that discriminate between different isoforms or post-translational modifications of osteopontin to determine if this trend can reach significance. By demonstrating OPN expression by neoplastic cells we can devise new protocols that evaluate its usefulness as a surrogate marker of tumoral activity in DLBCL using non-invasive techniques (*e.g.*, quantification of serum levels), which would improve surveillance of these patients.

PB1739

TREATMENT OF NEWLY DIAGNOSED CENTRAL NERVOUS SYSTEM LYMPHOMA PATIENTS BASED ON COMORBIDITIES & PERFORMANCE STATUS: A SINGLE-CENTRE EXPERIENCE

Y.J. Lim[1,*], J. Smith[1]
[1]Haematology, Aintree University Hospitals NHS Foundation Trust, Liverpool, United Kingdom

Background: Combination chemotherapy incorporating high dose methotrexate (HD-Mtx) and high dose cytarabine (Ara-C) is the standard chemotherapeutic approach for newly diagnosed primary CNS lymphoma (PCNSL). However, patients >60 years old account for 50% of cases and combining HD-Mtx with Ara-C can be associated with high toxicity and early mortality. The management of secondary CNS lymphoma (SCNSL) is less clear, but is often based upon a similar approach.
Aims: We present a tertiary centre experience in management of primary (PCNSL) and secondary CNS lymphoma (SCNSL), with therapy based on comorbidities and performance status.
Methods: We performed a retrospective analysis of patients with a diagnosis of CNS lymphoma seen at our centre between 2011 and 2016. These were categorized into 3 groups, Group 1: treatment of newly diagnosed PCNSL prior to September 2014 where majority of patients received HD-Mtx & Ara-C combination chemotherapy, Group 2: treatment of PCNSL after September 2014 where patients were selected based on co-morbidities to receive Mtx with or without Ara-C, Group 3: treatment of newly diagnosed SCNSL. The median survival for each group was estimated using the Kaplan-Meier method and log-ranked test. Overall response rates, 30 day and 90 day survival between groups 1 & 2 were compared using unpaired t test.
Results: 60 pts with a median age of 65 years old were recruited. 40 pts were diagnosed to have PCNSL at presentation, while 20 patients had SCNSL. 5 pts were excluded from this study as they did not receive any treatment. In group 1, 21 pts (84%) received combination chemotherapy incorporating HD-MTX and Ara-C, 3 pts (12%) received HD-MTX monotherapy and 1 pt (4%) received radiotherapy only. In group 2, 7 pts (53.8%) received HD-MTX and Ara-C as part of MATRix protocol or with single agent rituximab, 3 pts (23%) received HD-MTX as part of RMP protocol or with single agent rituximab, 1 pt (7.7%) received a single alkylating agent and 1 pt (7.7%) received radiotherapy only. In group 3 15 pts (88.3%) received chemotherapy incorporating HD-MTX and Ara-C, 2 pt (11.8%) received HD-MTX without Ara-C. 30 day mortality was 7 (28%) in group 1 and 0 in group 2 (0%) (p=0.03). 90 day mortality was 7 (28%) in group 1 and 2 in group 2 (15.4%) (p=0.39). Overall response rate was 9 (36%) in group 1 and 8 (61.5%) in group 2 (p= 0.13). A Kaplan Meier curve of all 3 groups is illustrated in Figure 1 below.

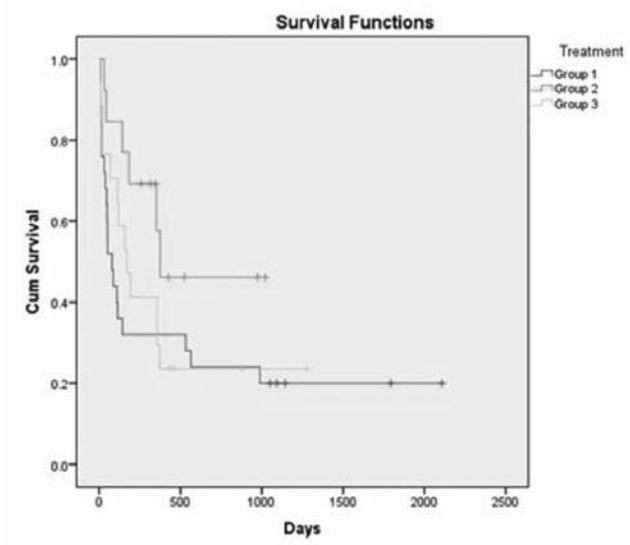

Figure 1.

Summary/Conclusions: This single centre study demonstrated that patient selection, based upon comorbidities and performance status, for high dose combination chemotherapy in the treatment of PCNSL improves 30 day mortality, often associated with death from myelosuppression due to chemotherapy. The overall response rate, with appropriate selection of combination chemotherapy regimens, was improved. This also applies to patients with SCNSL in subgroup analysis. Longer follow up of patients will be needed to further demonstrate an overall survival benefit.

PB1740

AN AUDIT OF THE USE OF RASBURICASE FOR THE PREVENTION AND TREATMENT OF TUMOUR LYSIS SYNDROME IN PATIENTS RECEIVING TREATMENT AT THE NORTHERN CENTRE FOR CANCER CARE, NEWCASTLE UPON TYNE, UK

E. Watts[1,*], S. Gabriel[1], G. Jones[1], R. Clark[2], S. Holmes[1]
[1]Haematology, [2]Renal Medicine, Freeman Hospital, Newcastle Upon Tyne, Newcastle upon Tyne, United Kingdom

Background: Tumour Lysis Syndrome (TLS) is a known complication of haemato-oncological treatment. Although clinical TLS is rare, the consequences are significant, with one third of affected patients requiring dialysis and an overall mortality rate of around 15%[1,2]. A new British Society for Haematology (BSH) guideline was published in April 2015 to guide physicians on how to risk stratify patients (based upon the Cairo Risk Stratification 2010[3]), choice of prophylaxis, and treatment of established TLS[4]. We audited all patients who received rasburicase at the Northern Centre for Cancer Care from 16th April 2015 to 3rd February 2016, and compared their management with BSH guidelines[4].
Aims: To compare our practice with BSH guidelines.
Methods: Retrospective review of electronic patient presciption records, biochemistry results, and paper notes.
Results: 27 patients received rasburicase in the study period. 20 patients met Cairo criteria/BSH criteria as having High Risk Disease (HRD) or Intermediate Risk Disease(IRD)/Low Risk Disease (LRD)with renal impairment, and therefore should have received 3mg rasburicase prophylaxis if no evidence of TLS according to the guideline. Of those 20, 11 had laboratory TLS, and therefore BSH guidelines would recommend 0.2mg/kg/day [JG1] rasburicase, however only 3/11 were given the drug at treatment doses. 1/3 had clinical TLS at presentation and received treatment according to the guideline. The 2 other patients received larger doses of rasburicase but less than the BSH would recommend. A further 7 patients with IRD received rasburicase prophylaxis but on review did not meet the criteria for rasburicase as set out in the guidelines. 5 patients died during the study period. 2 patients died on ITU of multi-organ failure <7 days into chemotherapy. A third patient died of sepsis, and the other 2 deaths were in deteriorating patients where a decision was made to palliate.
Summary/Conclusions: When assessed against BSH standards, all patients in this cohort who should have received rasburicase prophylaxis, were given the drug. 2 patients with lab TLS developed clinical TLS. 8 others with lab TLS received lower doses than the BSH would recommend, but did not progress to clinical TLS. Although there were 5 deaths in our cohort, none were directly attributable to TLS. In order to comply with the guidelines, particular importance must placed on formally assessing the TLS risk score as per Cairo

criteria at the outset and analyzing the possible features of laboratory TLS. Although dosing did not always follow BSH guidelines, we did respond to biochemical deterioration. The majority of patients with HRD developed acute kidney injury despite rasburicase. Doses were increased in response to creatinine increases, albeit not as per guideline. It is notable that despite lower than the recommended doses of rasburicase, 6/8 patients with lab TLS did not progress to clinical TLS, and none required dialysis. The guideline is a good tool for the risk stratifcation and treatment of patients at risk of TLS. In clinical practice 100% compliance is hard to achieve. Responding to trends in creatinine may explain why, despite lower than recommended doses, our outcomes were still good. It would be interesting to see if further work with larger numbers of patients would support this. Since this audit was completed, the ePrescribing system has been altered to improve practice and a re-audit is planned.

PB1741

IMPLICATION OF BASIC VALUES OF VITAMIN D IN THE CLINICAL COMPLICATIONS OF PATIENTS WITH NO HODGKIN LYMPHOMA IN ACTIVE CHEMOTHERAPY TREATMENT

R. Martos[1,*], D. Morillo[1], M. Yuste[1], L. Bermejo[2], A. Pascual[2], P. Beltran[2], N. Patrignani[2], P. Llamas[3]
[1]Hematology, Hospital General Villalba, Collado Villalba, [2]Hematology, Hospital Universitario "Infanta Elena", Valdemoro, [3]Hematology, Hospital Universitario "Fundación Jimenez Díaz", Madrid, Spain

Background: The incidence and prevalence of Non-Hodgkin's Lymphoma B (NHL-B) has increased in recent years, reaching approximately 3-7 cases / 100,000 habitants. For this reason, the number of patients who receive chemotherapy treatment is also considerably higher; this implies a greater presence of adverse events. In many of these patients, baseline vitamin D values at the time of diagnosis are decreased, and may be related to the development of the tumor pathology, also to the severity of the adverse events.
Aims: To assess the implication of vitamin D values in the development of relevant clinical complications in patients diagnosed with NHL-B receiving chemotherapy. To determine its clinical evolution after correcting the vitamin deficit.
Methods: Retrospective study (January2013/January2017),which includes patients diagnosed with NHL-B with histological confirmation. We analyze demographic parameters (age, sex), histological subtype of NHL-B according to WHO classification, laboratory values of vitamin D (cut-off values:optimal 25-66pg/mL; low 25-18pg/mL or very low<18pg/mL), adverse effects:hematological toxicity,infection,gastrointestinal toxicity,hospital admissions and exitus.A subanalysis of complications was performed in patients with vitamin D deficiency who received corrective treatment.
Results: 68patients were analyzed, and 57cases (84%) were valid because they had vitamin D determination in the 8weeks near the diagnosis. The distribution was:58% ♂(n=33)/42%♀(n=24),with median age 59years (range:29-91 years).The subtypes of LNH-B:Follicular n=23(40%),Diffuse large cell n=21(37%), Mantle n=6(11%), Marginal n=4(7%) and others n=3(5%).Patients were included in 3 groups according to serum vitamin D levels: patients with optimal levels (n=23;40%),low levels (n=27; 48%) and very low levels (n=7;12%). Hematological toxicities were higher for the subgroup with decreased vitamin D levels *vs* subgroup with level in range (28%*vs*72%) (p<0.01). Neutropenia was more severe (grade>2) in patients with very low levels of vitamin D(p<0.01).No patient with optimal vitamin D levels had severe anemia(Hb<8g/dl) or thrombopenia<70000/mm3, in relation to 28cases of severe toxicity diagnosed in vitamin D deficient groups. In this group were documented the two infections of the study (both pneumonias), a gastrointestinal toxicities(86%),hospitalizations for complications(69%) and only one exitus. After treatment, it was found that 74%(n=25patients) corrected levels, presenting a lower incidence of toxicity to the treatment *vs.*26%(n=9) who did not correct levels and presented more complications (especially hematological toxicity) more complex and durable.
Summary/Conclusions: Vitamin D deficiency in the diagnosis of patients with NHL-B has been correlated with a higher incidence of medical complications due to the treatment of chemotherapy. In our series, patients had greater hematological toxicity and greater severity (p <0.01), more infectious episodes and a higher hospital admission rate. These adverse effects are even more pronounced the lower the vitamin D levels (<18pg/mL). A study conducted by *Drake et al. (JCO, 2010)* on 980patients presents similar data, with a significantly higher incidence of complications in vitamin D deficient patients. After treatment with vitamin D, patients who corrected levels had a more favorable evolution with fewer hematological and infectious complications (p<0.01) in relation to those patients in whom the vitamin deficit persisted despite the treatment. At this time, the monitoring period is not completed, so the data related to OS and SLE still have to be updated and will be presented at the next congress. We believe that the determination of vitamin D levels should be routinely included in the diagnosis in patients with NHL-B because could be a modifiable risk factor in the complications of this patients.

PB1742

PROGNOSTIC IMPACT OF SYNCHRONOUS MULTIPLE PRIMARY MALIGNANT TUMORS ON NEWLY DIAGNOSED LYMPHOMA PATIENTS

S. Nishiwaki[1,2,*], S. Okuno[1], K. Suzuki[1], S. Kurahashi[1], I. Sugiura[1]
[1]Division of Hematology and Oncology, Toyohashi Municipal Hospital, Toyohashi, [2]Center for Advanced Medicine and Clinical Research, Nagoya University Hospital, Nagoya, Japan

Background: Synchronous multiple primary malignant tumors (sMPMTs) are occasionally diagnosed during screening for a newly diagnosed malignant neoplasm. Lymphoma is one of the most common hematological malignancies, and number of lymphoma patients with sMPMTs seems to grow as the population ages. Since the standard chemotherapy for lymphoma takes a few months, treatment strategy sometimes comes to an issue.
Aims: To answer a clinical question of how to handle sMPMTs in the treatment of lymphoma, we investigated prognostic significance of sMPMTs and suitable treatment strategy for a newly diagnosed lymphoma with sMPMTs.
Methods: We retrospectively analyzed patients with malignant lymphoma newly diagnosed between 2009 and 2015. The definition of sMPMTs was patients who were also diagnosed as a solid tumor within 6 months of the diagnosis of lymphoma. Therapeutic strategy was according to physician's choice. Impact of sMPMTs on treatment outcome of lymphoma was analyzed. Also, relation between treatment of lymphoma and concomitant solid tumors was closely analyzed.
Results: Total of 505 lymphoma patients was included. Median age was 69 (range20-99). The most common diagnosis was diffuse large B-cell lymphoma (63%), and patients with aggressive lymphoma accounted for 77% (391/505). High risk disease, which was defined as international prognostic score 3 or higher, accounted for 36% (184/505). sMPMTs were identified in 16 patients (3.2%). There was no difference of distribution between patients with and without sMPMTs regarding age, grade of lymphoma, and disease risk. The overall survival (OS) and disease-free survival (DFS) were not significantly different between the two groups (with sMPMTs: 53% and 47% *vs* without sMPMTs: 77% and 61% at 3 years, P=0.20 and P=0.31). Cumulative incidence of lymphoma relapse was similar between the two groups (with sMPMTs 29% *vs* without sMPMTs 27% at 3 years, P=0.28). In multivariate analyses, age (75 years<) and disease risk (high) were identified significant risk factors for OS, and age was an only significant risk factor for DFS. Existence of sMPMTs was not a significant risk factor for either OS or DFS (OS: HR 1.29, 95%CI 0.52-3.20, P=0.58; DFS: HR 1.06, 95%CI 0.49-2.27, P=0.88). Among 16 patients with sMPMTs, half of the patients had high-risk lymphoma, and half of the solid tumors were gastric cancer. Treatment was initiated for the disease which was diagnosed earlier in all patients except one. Interval from diagnosis to the first treatment was significantly shorter in patients whose lymphoma was treated earlier (median 11 days *vs* 38.5 days, P=0.004). OS was not significantly different according to the sequencing of treatment (lymphoma earlier: 59% *vs* Solid tumor earlier: 40% at 3 years, P=0.84). In 8 of 10 patients whose lymphoma was treated earlier, treatment of lymphoma was interrupted for the treatment of comorbid solid tumor. Interruption of treatment had no significant effect on OS (interruption+: 60% *vs* interruption-: 50% at 3 years, P=0.13).
Summary/Conclusions: Existence of sMPMTs was not a significant risk factor for newly diagnosed lymphoma patients. It is important to provide adequate treatment for both lymphoma and solid tumor at physician's discretion.

Bleeding disorders (congenital and acquired)

PB1743

GLOBAL HEMOSTATIC ASSAY AT DIFFERENT TARGET ACTIVITY OF FACTOR VIII AND FACTOR IX

K. Yoo[1,*]
[1]Korea Hemophilia Foundation, Seoul, Korea, Republic Of

Background: Based on reports addressing hemophilia B patients bleed less common and less intensively than hemophilia A, it has been expected that the hemostatic level of factor IX (FIX) activity can be lowered than that of factor VIII (FVIII) activity.
Aims: We compared the hemostatic efficacy of the different hemostatic level of FIX and FVIII activity using global hemostatic assay.
Methods: A total of 17 severe hemophilia patients without inhibitor, aged more than 15 years old were subjected; 12 hemophilia A patients and 7 hemophilia B patients. Factor concentrates were injected to reach the target activity of 60% in hemophilia A and 40% in hemophilia B which is given by Korean health insurance guideline. All patients were in non-bleeding state and kept the wash-out period of 3 days for hemophilia A and 5 days of hemophilia B. Before and on 15 minutes after injections, we conducted one-stage factor assay, thrombin generation assay (TGA), thromboelastography (TEG) and clot-wave form analysis (CWA).
Results: Median ages of hemophilia A and hemophilia B patients were 28 and 33 years old. Baseline FVIII:C and FIX:C were 0.6% and 1.8% and they rose after injection rose to 70.8% and 49.8%. The dosage of FVIII concentrates and recombinant FIX concentrates were 28.4 IU/kg and 50.7 IU/kg. In-vivo recovery (IVR) in hemophilia A and hemophilia B patients recorded 2.43%/U/kg and 0.91%/U/kg. Peak thrombin of FVIII and FIX were 451.3 nM and 376.6 nM (P=0.108, normal range, 458 nM±60). TEG index of FVIII and FIX were -1.60 and -3.77 (P=0.004, normal range, -2~+2). MIN2 of CWA of FVIII and FIX were 0.62 and 0.59 (P=1.000).
Summary/Conclusions: Global hemostatic assay indicates even though IVR of FVIII and FIX are normal, less amount of FIX is insufficient to normalize hemostatic parameters in comparison with FVIII.

PB1744

THE RATE OF SUCCESSFUL IMMUNOTOLERANCE INDUCTION IN HAEMOPHILIA A BOYS TREATED WITH OCTOCOG ALFA - THE EXPERIENCE OF POLISH PAEDIATRIC HAEMOPHILIA CARE CENTRES

A. Kołtan[1,2,*], A. Klukowska[3], P. Laguna[3], W. Badowska[4], W. Balwierz[5], G. Karolczyk[6], D. Pietrys[5], H. Bobrowska[7], M. Kostrzewska[8], T. Ociepa[9], T. Urasinski[9], I. Woznica-Karczmarz[10,11]
[1]Department of Peditrics, Hematology and Oncology, Collegium Medicum in Bydgoszcz, Nicoaus Copernicus University Torun, [2]Antoni Jurasz University Hospital No 1, Bydgoszcz, [3]Department of Peditrics, Hematology and Oncology, Warsaw Medical University, Warsaw, [4]Clinical Department of Hematology and Onkoloogii for children, Faculty of Medical Sciences at the University of Warmia and Mazury, Olsztyn, [5]Department of Oncology and Hematology, Institute of Pediatrics, Jagiellonian University Medical College, Krakow, [6]Onkology and Hematology Unit, Regional Hospital in Kielce, Kielce, [7]Department of Pediatrics and Hematology, Children Hospital in Poznan, Poznan, [8]Department Pediatric, Oncology, Hematology, Diabetology, Medical Univercity of Lodz, Lodz, [9]Department of Pediatric Hematology and Oncology, Pomeranian Medical University in Szczecin, Szczecin, [10]Department of Pediatric Hematology, Oncology and Transplantology, Lublin Medical University, [11]Department of Transfusion Medicine, Childrens Unversity Hospital in Lublin, Lublin, Poland

Background: Development of neutralizing anti-factor VIII alloantibodies (inhibitor; INH) is the most challenging complication of haemophilia replacement therapy (HRT). It occurs in up to 30% of severe haemophilia A (HA) patients. Data published recently indicate that immunotolerance induction (ITI) is effective in 62–87% of cases.
Aims: To assess the rate of successful ITI in boys with severe HA treated with full length recombinant FVIII (octocog α) in all Polish Paediatric Haemophilia Care Centres between 2011-2016.
Methods: From 2011 to 2016 in all Polish Paediatric Haemophilia Care Centres 14/88 (15.9%) boys with severe HA on prophylaxis or on demond treatment with octocog α developed INH after 3 - 489 (median 20) exposure days (EDs). Twelve of them (85.7%) were high responders with the peak inhibitor titre (PIT) 5,88 - 716.8 (median 20.1) BU/ml. Two patients were low responders (14,3%) and had PIT 2.8 and 3.02BU/ml. All except one boys were Caucasians and only one had a positive family history of INH formation. Characteristics of patients is given in Table 1.
Results: INH titres prior to ITI were 1.2 - 37 (median 6,75) BU/ml. One of low responders eliminated INH spontaneously, 1 patient is waiting for ITI initiation. ITI with octocog α was initiated in 12/14 boys after 0.2 to 8.2 (median 2.0) months from INH diagnosis and completed in 9 patients. Three patients are still on ITI. INH eradication was observed in 7/9 (77.8%) of those who completed ITI. Eradication of INH was not achieved in 2 patients; both have already started prophylaxis with activated prothrombin complex concentrate (APCC). The remaining 3 patients are still on ITI. All 7 patients after successful ITI were put back on prophylaxis with octocog α.
Summary/Conclusions: 1. Octocog α is effective in induction of immunotolerance in severe haemophilia A boys who developed inhibitor on prophylaxis with octocog α.

Table 1. Characteristic of patients.

Patient	Age at: 1st dose of FVIII / start of prophylaxis [mth]	Peak inhibitor titer BU/ml	Number of EDs at INH diagnosis	Type of treatment	Surgery	High doses of FVIII due to bleeding	Factor VIII given on: first day of infection / day of vaccination

APPROACH TO PREGNANCY IN NIEMANN PICK DISEASE TYPE B PATIENT

D. Agić[1,2,*], V. Dinic Uzurov[1], I. Miloševi[1], O. Rankov[3], P. Milosevic[4], G. Mitic[5], I. Kavecan[6], S. Stojic[3]
[1]Clinic for hematology, Clinical Center Vojvodina, [2]Medical Faculty, University of Novi Sad, [3]Clinic for gynecology and obstetrician, [4]Clinic for abdominal and endocrine surgery, [5]Department for trombosis, hemostasis and hematology diagnostic, Clinical Center Vojvodina, [6] Center for Medical Genetics, Institute for Children and Youth Health Care of Vojvodina, Novi Sad, Serbia

Background: Niemann Pick Disease type A and B is a rare autosomal recessive disorder caused by sphingomyelinasa deficiency resulting in sphingomyelin accumulation in macrophages of varies organs. In type B usually patients survive in adulthood. Usually, they have hepatosplenomegaly, thrombocytopenia, and dyslipidemia. Lung and liver function are influenced, and they have bleeding risk.
Aims: Pregnancy in this situation is always risky and multidisciplinary approach is needed. Searching on Medline we found only two case reports of childbirth by women with this condition.
Methods: We presented a case of pregnancy in 34 year old women with Nieman Pick disease type B. She had marked splenomegaly, mild thrombocytopenia and partial respiratory insufficiency. Previously, she had two artificial abortions without more than expected bleeding. Also she had surgery of left side inguinal hernia and after that she was given platelet concentrates. Risk factors for pregnancy were presented to her.
Results: Laboratory controls were done periodically, ultrasound examination of abdomen and portal vein system, lung capacity and echocardiography were performed, too. Results of CBC were stable. Repeated tests of hemostasis were normal. Hyperlipoproteinaemia type IIb with hypoHDL cholesterolemia was present. We assumed that platelets dysfunction could exist, therefore before planned amniocentesis we performed platelets aggregation tests with ADP, TRAP and collagen. All of them were below lower limit: ADP 43 (55-117), TRAP 71 (92-151), col. 30 (61-108). Ultrasound examination of abdomen and portal vein sistem revieled liver diameter 17cm, craniocaudal diameter of spleen 22cm, portal vein had not been seen. There were no sign of trombosis in portal branches. Amniocentesis was done without complication and there was no need for platelet substitution. Normal male kariotype was found. We prepare her for planned caesarian section with platelet concentrates. She was given corticosteroids for lung maturation. In 35^{th}+5d gestational week she was operated. Before surgery platelets count was $87x10^9$/l, she was given seven concentrates of platelets (1 per 10 kg body weight) before and seven during procedure. She also received antibiotic prophylaxis. Newborn was 47cm, 2490g weight and Apgar score was 7/8. There was no major blood loss and no need for red blood cell transfusion or platelets transfusion in follow up period. We decided not to make splenectomy or partial resection because there were no significant differences in spleen measurements before and during the pregnancy, and there was no sign of spleen trauma. Also, in literature we found data about worsening lung function after this procedure caused by more shingomyelin accumulation in pulmonal tissue. Published data and findings of abnormal platelet function in our patient and experience with previous abdominal surgery led our decision to give her platelet concentrates before section and according to obstetrician's estimation during the operation. Pregnancy did not cause health state deterioration in our patient and there are no clinical findings of Niemann Pick disease in newborn.
Summary/Conclusions: We presented a case of pregnancy in 34 year old women with Nieman Pick disease type B. Marked splenomegaly, mild thrombocytopenia and partial respiratory insufficiency existed before this pregnancy. Decisions about diagnostic assesment, platelet transfusion, splenectomy, and

dyslipidemia treatment were made upon data from literature and patient's findings. Multidisciplinary approach in this setting is needed. Bleeding risk is not connected only with platelet count, but also with their function and degree of splenomegaly. Liver function can also be disturbed and can influence hemostasis. Pregnancy in our patient did not cause health state deterioration and there were no clinical findings of Niemann Pick disease in newborn.

PB1746

SINGLE CENTRE FX DEFICIENCY EXPERIENCE

Z. Baslar[1,*], S. Sadri[1], I. Erdogan[1], M.C. Ar[1]
[1]Internal medicine- Hematology, Istanbul University, Cerrahpasa Medical Faculty, istanbul, Turkey

Background: Factor X is a vitamin K–dependent serine protease that works at the crossroads of the extrinsic and intrinsic pathways to cleave prothrombin into thrombin. Inheritance pattern of factor X deficiency is autosomal recessive, with heterozygote patients most often remaining asymptomatic or having only a mild bleeding phenotype. (1) Homozygous individuals may experience haemorrhagic symptoms, including easy bruising, haematuria, soft-tissue haemorrhages, haemarthroses, recurrent epistaxis, and menorrhagia (2) Congenital factor X deficiency is among the most rare factor disorders. We present here our experience with patients having congenital factor X deficiency.
Aims: We aimed to present our experience with rare FX deficiency in our centre.
Methods: There are currently 4 patients with factor X deficiency (F/M: 3/1) that are followed at our centre.
Results: First patient is 40 years old man who got his diagnosis at the age of 31 years following a gastrointestinal bleeding. He was treated with fresh frozen plasma (FFP) at that time. His FX was found:%0. Two years later underwent a planned tooth operation under the coverage of prothrombin complex concentrate (PCC) (Table 1). Three years after the tooth extraction he underwent an intraocular lens operation under PCC prophylaxis. No complication was observed while on PCC treatmet.

Table 1.

weight : 70 kg	PCC
Operation day	750 unit
2nd day	500 unit
4th day	500 unit
6th day	250 unit

Our second patient is a woman who was diagnosed at the age of 3 because of recurring gum bleeding. She has been treated with FFP replacement throughout her childhood and adolescence due to recurring nose and soft tissue bleeds as well as menorrhagia. She was first referred to our hospital at the age of 42 due to soft tissue bleeding. Given the lack of health insurance she mainly received FFP and tranexamic acid tablets during most of her bleeding attacks. However, PCC of 1000 unit for two days had to be used for her excessive vaginal bleeding irresponsive to FFP. Her number of annual bleeding is 15-20 times in a year and most of them are gum bleeding and rarely vaginal bleeding. Third and 4th patients were referred to our centre because of prolonged the prothrombin time (PT) and the activated partial thromboplastin time (aPTT) and received the diagnosis of FX deficiency.
Summary/Conclusions: Bleeding phenotype differs in a wide range in patients with congenital FX deficiency. Secondary causes including amyloidosis should be excluded especially in patients receving diagnosis at advanced ages. Usually the factor level does not correspond to the severitiy of the bleeding phenotype. Therefore bleeding pattern of the patients with FX deficiency should be carefully observed and considered while planning a prophylactic treatment with PCCs to prevent the risk for thrombosis and unnecessary utilisation of PCCs. FFP and PCCs replacement continue to be the source for FX in bleeding patients or in individuals requiring prophylaxis. Recently, a FX concentrate has entered the market in the USA and the Europaen Community.

PB1747

IMPROVEMENT OF THE SURVIVAL FOR LIFE-THREATENING HEMORRHAGE WITH HEMOPHILIA PATIENT

K.S. Lee[1,*], J.Y. Kim[2], J.K. Seo[2], S.Y. Hyun[3]
[1]Kyungpook National University School of Medicine, [2]Kyungpook National University Children's Hospital, Daegu, [3]Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic Of

Background: In life threatening hemorrhage such as brain and abdomen, several important factors are affect for improving the survival. One tenth (223) of hemophilia patients in Korea lived in Daegu city and Kyungpook province and have treated in our regional treatment center.
Aims: We reviewed the result of life threatening hemorrhage and our unique care of hemophilia patients for 34 years.
Methods: Korea Hemophilia Foundation was established in 1991. After that all factor concentrates were free to all hemophilia patients. Home treatment are available for rapid administration of factor concentrate of full required amount. Rapid transportation to emergency room are available for immediate operation. Hot line of mobile phone between patient and doctor for 24 hours are available for emergency care. Monthly group education has done. Prophylactic treatment was started to all who had a life threatening hemorrhage history in our hospital since 1996. But HIRA permitted officially since 2011.
And then recovery rate test was done for the optimal blood level for life threatening hemorrhage patient. Continuous infusion with every 2 to 4 hours reconstitution dilution fluid has been done for preserve *in vitro* factor activity to all surgery cases.
Results: Thirty five events were intracranial hemorrhage in 17, general surgery in 9 and orthopedic surgery in 9. Age distribution was 0-32 yr (mean; 24.8 yr). Severity was severe (16), moderate (7) and mild (5). Time interval between first symptom and arrival at ER were 15 min to 10 days (mean; 1.7days). We confirmed *in vivo* factor activity within permissible level in all patients. All recovered from hemorrhage or surgery and are healthy, but one had limping gate and one had mild neurologic sequela for more than 10 years follow-up period.
Summary/Conclusions: Education, financial support, home and prophylactic treatment, hot-line, individual pharmacokinetics with effective blood level and fresh concentrate during continuous infusion are important factors to improve the survival of surgery case.

PB1748

CAN BLEEDING SCORE AND FACTOR LEVELS DETERMINE HEMOPHILIA CARRIERS?

Y. Ay[1,*], A. Çakıl[2], S. Okur Acar[1], E. Töret[3], T. Hilkay Karapınar[1], Y. Oymak[1], S. Gözmen[1], C. Vergin[1]
[1]Division of Pediatric Hematology, [2]Depatment of Pediatrics , Dr. Behçet Uz Children Disease and Surgery Training and Research Hospital, Izmir, [3]Division of Pediatric Hematology, Balıkesir Atatürk State Hospital, Balıkesir, Turkey

Background: Hemophilia A and B are X-linked recessive hemorrhagic disease. Due to this type of inheritance, males are usually affected, but girls are carriers. Factor levels are usually detected around 50% because only one chromosome is affected in carriers. Inconsistently, it has been reported that factor activity can be detected in a wide range of 22% -116% as a result of random inactivation (lyonization) of one of two X chromosomes. It is specified that factor levels may be very low due to excessive inactivation in a significant part of the hemophilia carriers, which creates a risk of bleeding in carriers.
Aims: In this study, we aimed to investigate the role of bleeding score and factor levels in detecting hemophilia carriers.
Methods: Bleeding Assessment Tool (BAT) for hereditary factor deficiencies of the International Society on Thrombosis and Haemostasis (ISTH/SSC) were applied to the mother and sisters of 32 hemophilia patients who were followed-up in Dr Behçet Uz Children's Diseases and Surgery Training and Research Hospital. Mothers whose at least one of the other members of the family and their sons had hemophilia, mothers with more than one hemophilic son and girls whose father had hemophilia were evaluated as an obligate carrier. Sisters or mothers who do not meet the obligatory carrier criteria but whose siblings or sons are hemophilic were identified as possible carriers. Factor activity of obligate or probable carriers was studied after their informed consent was obtained.
Results: Thirty-two mothers and 13 sisters of hemophilia patients were included in this study. The mean age was 31.6 (4-57) years. Three of the patients were mild, 3 were moderate, 23 were severe hemophilia A; 2 were severe and 1 had moderate hemophilia B. Twelve were obligate and 33 were probable carriers. Only seven in 45 (15.5%) probable and obligate hemophilia carriers had high bleeding scores (≥4). Those with high bleeding scores, three were obligate carriers and four were probable carriers. The mean factor activity of 12 obligate and 18 probable carriers were 78.9% (20.8%>189%). Factor activities of the three obligate carriers with high bleeding scores were 77%, 80% and 98%, respectively. Factor activities of the three probable carriers with high bleeding scores were 58.8%, 69.3% and 112%, respectively. The median bleeding scores of four probable and one obligate carriers with low factor activity (<60%) were 2.8 (1-4).
Summary/Conclusions: Measurement of factor activity seems to be insufficient to detect hemophilia carriers**.** ISTH/SSC-BAT may help to determine the carriers. However, a larger study is needed to understand the diagnostic value of the BAT.

PB1749

FETAL INTRACRANIAL HEMORRHAGE AS A PRESENTING FEATURE OF SEVERE CONGENITAL FACTOR VII DEFICIENCY: THE NEED FOR EARLY PROPHYLAXIS

M. Elshinawy[1,*], A. Alrawas[2], Y. Wali[2]
[1]Pediatric Hematology, SQUH, University of Alexandria, Oman, Egypt, [2]Pediatric Hematology, Sultan Qaboos University Hospital, Muscat, Oman

Background: Congenital factor VII (FVII) deficiency is a rare autosomal reces-

sive bleeding disorder, with an estimated prevalence of 1:300,000. Compared to western countries, rare bleeding disorders (RBDs) are relatively commoner in Oman, owing to high rate of consanguineous marriage.
Aims: To discuss an interesting case fo severe congenital factor VII deficiency and to explore the need for early prophylaxis.
Methods: Case report and retrospective data analysis of all children diagnosed with inherited coagulation factor deficiencies in Pediatric Hematology Unit, Sultan Qaboos University Hospital, Muscat, Oman from January 2009 till December 2016.
Results: We report a male full term baby, delivered by cesarean section. His older sister is a known case of severe congenital factor VII deficiency. Antenatal scans of this baby revealed two intracerebral hematomas and dilated cerebral ventricles. Postnatally, the diagnosis of severe congenital FVII deficiency was confirmed. CT scan revealed obstructive hydrocephalus at the level of aqueduct of Sylvius (Figure 1). At day 10 of life, ventriculo-peritoneal shunt has been done successfully under cover of recombinant activated factor VII replacement therapy. Afterwards, the patient has been initiated on rFVIIa prophylaxis at a dose of 30 ug/kg three times weekly. In our center, deficiencies of fibrinogen, FV, FVII, FX and FXIII were diagnosed in 22 pediatric patients (10 males and 12 females), accounting for 11.1% (22/198) of all children with inherited coagulation factor deficiencies. The age ranges from 1 day to 6 years and consanguinity is found in 19/22 cases (86.4%). Hypofibrinogenemia, FV and FVII deficiency are the commonest RBDs, diagnosed in 8, 6 and 5 patients respectively. As an initial presentation, intracranial hemorrhage occurred in 7/22 cases (31.8%). Three patients with FV, FVII and FXIII deficiencies suffered from global developmental delay due to severe intracranial hemorrhage. As regards management, 4 patients with severe FV deficiency and one with severe FXIII deficiency are on fresh frozen plasma (FFP) and recombinant FXIII prophylaxis respectively. Other patients receive on-demand therapy.

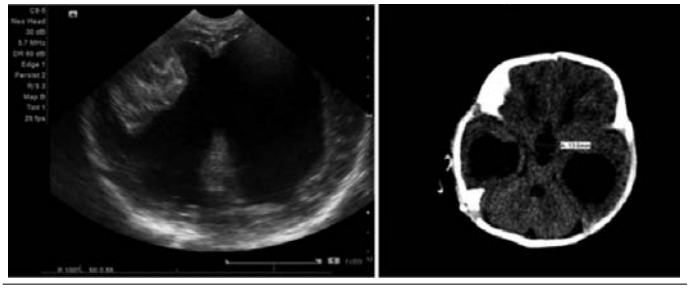

Figure 1.

Summary/Conclusions: Children with RBDs constitute more than one tenth of cases of hereditary coagulation factor deficiencies in our center. They have some unique features in terms of severity, clinical profile and the need for prophylaxis early in life. We recommend establishing a national/regional registry of RBDs to identify the magnitude and the peculiar genotype-phenotype correlations of such rare, yet significant disorders.

PB1750

THE ASSOCIATION OF BLOOD TYPE WITH THE NEED FOR TRANSFUSIONS IN PATIENTS WITH VENTRICULAR ASSIST DEVICES

T. Kanellopoulou[1,*], M. Aliberti[1], A. Apostolou[1], M. Fidirikou[1], S. Georgantis[1], E. Kabana[1], M. Katafigioti[1], P. Litras[1], A. Makrigianni[1], N. Matoula[1], E. Papadaki[1], G. Soufla[1], E. Zalachori[1], T. Kostelidou[1]
[1]Department of Haematology and Blood Transfusion, Onassis Cardiac Surgery Centre, Athens, Greece

Background: Patients who have implantation of continuous flow ventricular assist devices (VAD) as a bridge to heart transplantation are subjected to complications secondary to pump support. The use of antiplatelets either alone or in combination with acticoagulation is necessary to avoid clot formation and pump thrombosis. However, a proportion of patients reveal an increasing risk of bleeding episodes. A possible reason of this situation could be that high shear forces lead to devastation of high molecular weight von Willebrand factor (vWF) making it functionally inactive and resulting in acquired von Willebrand disease (vWD). People with blood type O have lower baseline vWF levels and this abnormality could exacerbate the bleeding risk of patients with blood type O with VAD, resulting in more frequent bleeding episodes and need for transfusions.
Aims: The aim of current study was to investigate the possible association of blood type with acquired vWD induced by VAD, with the need for transfusions.
Methods: In this retrospective study, 17 patients who had a VAD implant in our hospital in a six-month period were included for analysis. The investigation of underlying vWD was estimated by ristocetin-induced platelet aggregation (RIPA) using classical light transmission aggregometer.
Results: Six patients (35.3%) had left-VAD (L-VAD) implantation while the others had biventricular VAD implantation (BiVAD). The mean age was 42.41 years (SD±15.33) and 9 patients (52.9%) were male. Female patients had VAD implantation at younger age than male ($p<0.001$). The mean follow-up after VAD implantation was 15 months (SD±11.88). At the time of analysis, 13 patients (76.5%) were alive, 2 patients (11.8%) had died while 2 patients (11.8%) had been heart-transplanted. Eight patients (47.1%) had blood type O, 8 patients (47.1%) had blood type A and a patient (5.9%) had AB. Mean RIPA before VAD implantation was 59.3% (SD±14.76) while after VAD implantation was 47.29% (SD±15.47), whereas the decrease was no statistically related. No statistical correlation was found between RIPA among different blood types. Among patients with blood type O, the need for blood transfusions was associated with the duration of having the VAD implantation in months ($p<0.001$) while the need for fresh frozen plasma (FFP) transfusions was associated with RIPA before VAD implantation ($p=0.016$). In non-blood O type patients no statistical correlation was found with the need for transfusions with RIPA percentage or median follow-up of patients.
Summary/Conclusions: It has been shown by several studies that patients with VAD show a decrease in vWF increasing the bleeding risk. Thus the best antiplatelet treatment and/or anticoagulation that those patient needs, remains challenging. In our study, there was a decrease in mean RIPA percentage after VAD implantation and patients with blood type O had lower RIPA before implantation. However, none of these measurements was statistically significant. The blood type O patients showed an increased need for transfusions in correlation with the duration of VAD implants and an increased need for FFP in correlation with RIPA baseline. Our study has limitations due to the small population and the fact that vWF was not estimated within the different blood groups at baseline and after VAD implantation.

ACQUIRED PURE RED CELL APLASIA ASSOCIATED WITH LYMPHOPROLIFERATIVE DISEASES IN ERYTHROPOIETIN-REFRACTORY ANEMIA PATIENTS ON DIALYSIS

K. Yoshinaga[1,*], N. Mori[1], M. Ohwashi[1], M. Ishii[1], M. Shiseki[1], J. Tanaka[1]
[1]Department of Hematology, Tokyo Women's Medical University, Tokyo, Japan

Background: Erythropoietin-refractory anemia is a serious problem and complicated causes should be ruled out in patients on dialysis. Acquired pure red cell aplasia (PRCA) may be hidden behind anemia of chronic kidney disease. Recently it was reported that PRCA patients with large granular lymphocyte frequently had *STAT3* mutations (Oie ZY *et al.* J Hematol & Oncol 2013, Ishida F *et al.* Cancer sci 2014). Molecular or flow-cytometric analysis is useful for detecting a small amount of abnormal lymphocytes.
Aims: We conducted this study to determine the clinical characteristics and *STAT3* mutations of patients with acquired PRCA on dialysis with lymphoproliferative diseases.
Methods: In our hospital, 4 patients were diagnosed as having acquired PRCA on dialysis with lymphoproliferative diseases after 2005. Patients were retrospectively studied for presenting feature, laboratory data, and clinical course. Surface markers of lymphocytes were examined by flow cytometric analysis, and T-cell receptor (TCR) rearrangements were examined by Southern blot analysis. Mononuclear cells were separated after obtaining written informed consent. *STAT3* (Y640F and D661Y) mutations were examined by allele-specific PCR. Current study was conducted within the guidelines and with the approval of the institutional ethical committee.
Results: In spite of adequate administration of erythroid colony-stimulating factor, all 4 patients required blood transfusion due to erythropoietin-refractory anemia. Median leukocyte and lymphocyte counts at diagnosis were 4650/mL (range, 3180-4850) and 1794 mL (range, 1183-2859), respectively. Two patients (Cases 1 and 2) had low percentage of CD4+ CD8+ by flow-cytometry and TCR C beta1 and gamma rearrangements by Southern blot analysis. Another patient (Case 3) had high percentage of gamma-delta T cell component (66.2%) with TCR delta rearrangement. The other patient (Case 4) had high CD16+CD56+ NK cell percentage without TCR receptor rearrangement. The median duration from the start of dialysis to onset of PRCA was 13 years (range, 5-19 years). Of the 4 patients, only one patient (Case 3) had the mutations of the *STAT3* gene (Y640F). This patient first received cyclophosphamide but he did not respond to the therapy. He subsequently received cyclosporine (CyA). The other three patients received CyA as an initial therapy, and it was effective in all 4 patients. Median follow-up were 7 years from diagnosis, and two patients died during follow-up period. One patient (Case 4) died of cardiac failure 7 years from the diagnosis. Another patient (Case 2) developed diffuse large B-cell lymphoma 5 years after the administration of CyA. He was treated with R-CHOP chemotherapy and complete remission (CR) was achieved. Although he had been in CR, he died of refractory pancytopenia with infection, 2 years after the lymphoma onset. The other two patients are still alive without blood transfusion for 6 and 7 years.
Summary/Conclusions: A proportion of erythropoietin-refractory anemia patients on dialysis have acquired PRCA associated with lymphoproliferative diseases. The combined analyses of flow-cytometry and TCR rearrangement of lymphocytes were useful for diagnosis of acquired PRCA associated with lymphoproliferative diseases. Further accumulations of patients were required for understanding the pathogenesis of lymphoproliferative diseases causing acquired PRCA on dialysis.

PB1752

ADULT PATIENTS WITH ACQUIRED PURE RED CELL APLASIA: TREATED BY CYCLOSPORINE A OR CORTICOSTEROIDS□SIMILAR EFFICIENCY

X. Wu[1,*], S. Wang[1], W. Shen[1], G. He[1], J. Li[1]
[1]Hematological Department, The First Affiliate Hospital, Nanjing Medical University , Jiangsu Province Hospital, Nanjing, China

Background: Adult pure red cell aplasia (PRCA) is a syndrome characterized by a severe normocytic anemia, reticulocytopenia, and absence of erythroblasts from an otherwise normal bone marrow. Immunosuppressive therapy has been used as the initial treatment foracquired chronic PRCA.
Aims: This article aims to evaluate the efficacy of cyclosporine A, and/or corticosteroids, and possible factors influencing it.
Methods: 34 cases of PRCA were retrospectively analyzed at our institution. Clinical data of 23 inpatient cases and 11 outpatient cases since 2009 October were collected. These patients were treated by cyclosporine A (CsA), and/or corticosteroids (CS), or other immunosuppressive agents if become refractory and relapsed.
Results: 31 patients were evaluated in our institution (one patient lost to follow-up and two patients with short observation period). The remission induction therapy included CsA (n=13), CS (n=13), or a simultaneous combination of CsA and CS (n=5). The initial response rate of CsA alone, CS alone, combination of CS and CsA were 69.2%, 46.2%, 80%, respectively (*P=0.422*). There was no statistical difference in response rate and CR rate between CsA-containing group and CS group, although the patients treated with CsA had a better response than those treated with CS (response rate 72.2%*vs* 46.2%, *P=0.262*; CR rate 33.3% *vs* 23.1%, *P=0.696)*. Including patients who had crossed over from other treatment groups, the cumulative response rate of CsA, CS, combination of CS and CsA, was 73.7% (14/19), 46.7% (7/15), 83.3% (5/6), respectively (*P=0.193*); the cumulative rate of CR was 26.3% (5/19), 26.67% (4/15), 66.7% (4/6), respectively (*P=0.202*). In 23 refractory and relapsed PRCA patients, 8 out of 12 (66.7%) refractory patients and 4 out of 11 (36.4%) relapsed patients achieved remission. The response rate of treatment with traditional immunosuppressive agents (CS and/or CsA) was higher than other immunosuppressive agents (65.0% *vs* 20%, *P=0.014)*.
Summary/Conclusions: CsA and/or CS are effective similarly in treating PRCA. For patients with relapse or refractory PRCA, there were no satisfactory treatment measures if CsA and/or CS were not be administered or un-effective. It was still needed to explore a more effective therapy for them.

PB1753

REACTIVATION OF HEPATITIS B VIRUS INFECTION IN APLASTIC ANEMIA PATIENTS

S. Wang[1,*], X. Wu[1], G. He[1], W. Shen[1], J. Li[1]
[1]Hematological Department, The First Affiliate Hospital, Nanjing Medical University , Jiangsu Province Hospital, Nanjing, China

Background: There is litter data about the influence of infection of HBV impact on the therapy of aplastic anemia.
Aims: This article is aimed at assessment the HBV reactivation risk in HBsAg-positive or HBsAg-negative, antihepatitis B core antigen antibody (anti-HBc) - positive patients with AA receiving CsA and/or ATG.
Methods: We analysis the clinical data of 60 AA patients with HBV infection out of 201 cases of AA from our center at AA diagnosis during the recent 3 years, and laboratory test data such as levels of liver enzyme, HBV DNA in serum, HBsAg anti-HBs and anti-HBc were monitored. Entecavir (ETV) or lamivudine □LAM□ was started when HBV reactivation (defined as detectable HBV DNA) was encountered or as a antiviral prophylaxis regimen for some HBVsAg-positive patients.
Results: Among 60(29.8%) AA patients, 12 were chronically infected (HBsAg positive) and 48 were previously exposed (HBsAg negative/anti-HBc positive). 5 patients (8.33%) who were HBsAg positive and not given any rophylactic antiviral therapy suffered HBV reactivation. 7 patientswho were HBsAg positive but given were found no HBV reactivation. All the 48 patients with negative HBsAg and positive anti-HBc were found no HBV reactivation during the follow-up.
Summary/Conclusions: Antiviral prophylaxis should be recommended for HBsAg-positive patients who will receive IST with AA as they had high rate (41.6%) of HBV reactivation. HBV infection were found no influence to the clinic course in AA and antiviral therapy had no influence to the effect of IST.

MULTICENTER RESULTS OF SCHWACHMAN-DIAMOND SYNDROME PATIENTS

S. Unal[1,*], N. Kalkan[1], T. Celkan[2], G. N. Ozdemir[2], N. Ozbek[3], N. Yarali[4], H. F. Cakmakli[4], I. Yenicesu[5], S. F. Celik[6], H. Kizilocak[2], M. Gokce[7], N. Guleray[8], M. Cetin[1], F. Gumruk[1], N. Akarsu[8]
[1]Hacettepe University, Divison Of Pediatric Hematology, Ankara, [2]Cerrahpasa Universiry, Department of Pediatric Hematology , Istanbul, [3]3Ankara Çocuk Sagligi ve Hastalıklari Hematoloji Onkoloji Egĭtim ve Arastırma Hastanesi , [4]Ankara Çocuk Sagligi ve Hastalıklari Hematoloji Onkoloji Egĭtim ve Arastırma Hastanesi , [5]Gazi University, Department of Pediatric Hematology, [6]Hacettepe University, Medical Faculty , Ankara, [7]Istanbul Saglik Bilimleri University, Department of Pediatric Hematology, Istanbul, [8]Hacettepe University, Deparment of Medical Genetics, Ankara, Turkey

Background: Shwachman-Diamond syndrome (SDS) is an autosomal recessively inherited disease characterized with neutropenia, exocrine pancreas insufficiency, failure to thrive and skeletal abnormalities. In approximately 90% of the patients, the molecular defect is related to SBDS gene mutations. The classical triad is present in one-forth of the patients and a high degree of suspicion is required in order to make the diagnosis. In this study, molecular work-up to patients with suspected SDS were made and the clinical and laboratory findings that predict the SDS diagnosis were investigated.
Aims: Aim of the study was to find out the predictive clinical and laboratory characeteristics of SDS patients.
Methods: The patients who were sent to Hacettepe Inherited Bone Marrow Failure Center for molecular work-up between June 2015 and August 2016 were evaluated with clinical and laboratory data obtained from a standardized patient registry form.

Results: Molecular work-up was performed in 20 patients referred to our center with a suspected diagnosis of SDS. Of these 20 patients (12 girls), 4 (20%) (3 boys) were found to have mutation in SBDS gene. The median age of these patients was 3.2 years (1-18). Of the 4 patients with genetically verified SDS, 1 (25%) had history of chronic diarrhea and pancreas atrophy was detected in ultrasonography of that patient Another patient (25%) with SDS had skeletal abnormality, and 3 (75%) of the patientshad failure to thrive. Three patients (75%) had anemia associated to neutropenia, and 1 patient (25%) had pancytopenia at presentation. On the other hand of the patients who were referred with a suspicion of SDS but was found to have no mutation, 43% had neutropenia, 25% had bicytopenia, 10% had pancytopenia. The patientsin the latter group had failure to thrive in 25% of the patients and chronic or persistent diarrhea was present in 25% of this group. There was no statistically significant difference in the clinical and laboratory parameters of the genetically verified SDS patients and patients without SDS but was referred with SDS suspicion.
Summary/Conclusions: Although, there was no statistically significant difference in the clinical and laboratory parameters of the genetically verified SDS patients and patients without SDS but was referred with SDS suspicion, this might be attributed to the small sample sizes. Compatible with the previous literature data, SDS is a cryptic disorder and the classical triiad is not commonly fulfilled in most of the patients. On the other hand, failure to thrive/growth retardation was three times more common in patients with SDS. Thus, in patients neutropenia, accompanying failure to thrive/growth retardation might be an indicative to make molecular work-up for SDS. Additionally, not only neutropenia, but bicytopenia or pancytopenia might be the hematological presentational findings of SDS.

Universitario La Paz , Madrid, [3]Hematology, Hospital Universitario Cruces, Bilbao, [4]Hematology, Hospital Clínico San Carlos, Madrid, [5]Hematology, H. Universitario Vall d´Hebron , Barcelona, [6]Hematology, H. Universitario Príncipe de Asturias, Madrid, [7]Hematology, H. Universitario Miguel Servet , Zaragoza, [8]Hematology, H. Clínico Universitario Virgen de la Arrixaca, Murcia, [9]Hematology, H. Universitario Donostia , Bilbao, [10]Hematology, H.Universitario Germans Trias i Pujol, [11]Hematology, H. Parc Tauli , Barcelona, [12]Hematology, SEHH, Madrid, Spain

Background: Aplastic anaemia (AA) and Paroxysmal Nocturnal Hemoglobinuria (PNH) are included, together with other pathologies, within the bone marrow failure syndromes (BMFS). In the present time, these clinical entities cannot be understood as independent pathologies, due to the extremely frequent evolution among them and with other BMFS, along with the development of new clones in the context of haematopoietic stem cell's kinetics.
Aims: The aims of this study were analyzing and comparing the behaviour of patients who suffered from PNH with pancytopenia with respect to that of patients who were initially diagnosed of AA and who later developed a PNH clone.
Methods: A clinical form was elaborated and distributed among the investigators of the PNH Spanish Registry. Clicnical, laboratory and treatment data of the patient were asked. Soon after, a descriptive analysis of the data was performed.
Results: 34 patients were recruited and analyzed (12 women and 22 men). Their age interval ranged from 2 to 87 years, and all of the patients suffered from either PNH with pancytopenia and/or AA with a developing PNH clone. The average age at the time of initial diagnosis was 28,5 years old (4m-72y). The initial diagnosis was: PNH with pancytopenia (1), moderate AA (16), severe AA (10), very severe AA (7). 15 patients presented a PNH clone in their granulocytes and/or monocytes at the time of diagnosis, being 24% the average of such clone (0-08-95%) and less than 2% in 7 patients. All of the cases that showed hemolitic signs at diagnosis presented clones >20%. The time of the clone's development in the remaining cases was 8,7 years (5m-28y), appearing in 2 patients just after resolution. Patients with AA received an average of 3 treatments, mostly cyclosporine with/without ATG (anti-thymocyte globulin). 10 patients underwent HCT (7 allogeneic HCT and 3 matched unrelated-donor HCT). 14 patients received eculizumab, being 88.2% the average size of the PNH clone at diagnosis (65-99%). Treatment response with eculizumab was total in 11 cases and partial in 3. The following complications were observed: cholelithiasis (3), renal failure (6; 50% secondary to treatment), iron overload that required chelation therapy (3), transient aplastic crisis due to parvovirus B19 (1), HCV infection (1), thrombosis (6). 4 patients started anticoagulant treatment prior to eculizumab with no evidence of further thrombosis once the treatment was initiated. 28 patients remain alive (26 of them with very good quality of life). 3 of them died due to HCT-complications and follow-up was lost in the 3 remaining cases.
Summary/Conclusions: Clonal evolution in AA is frequently associated with the development of a PNH clone at the time of diagnosis, throughout the pathology' natural course or even after disease's resolution. The development of such clone has been related to better prognosis in AA right after the immunosuppressive therapy (IST). Our experience demonstrated the presence of hemolisis in at least half of the cases, making it necessary in these patients treatment with eculizumab, generally obtaining a very good response.

PB1756

AUTOIMMUNE CYTOPENIAS IN PRIMARY IMMUNODEFICIENCY DISEASES: SINGLE CENTER EXPERIENCE

T. Patiroglu[1,*], M. Cansever[2], F. Bektas[2]
[1]Pediatric Hematology, [2]Pedıatric Immunology, Erciyes University Medical Faculty, Kayseri, Turkey

Aims: Primary immunodeficiency diseases (PID) are associated with hematologic complications such autoimmune hemolytic anemia (AIHA) and thrombocytopenia (ITP). The most common autoimmune cytopenia is ITP. Although ITP is observed in 7.6% of patients with PID, AIHA is seen at 4.8%. Also, we aimed to present the patients who had autoimmune cytopenias and PID.
Methods: Fifty six PID patients who were followed at the Pediatric Immunology Department of Erciyes University Medical Faculty (they were analyzed genetically) were evaluated retrospectively. Autoimmune cytopenias such as ITP and AIHA were detected in 9 (%16. 07) of the patients (combined immunodeficiency:4 patients, common variable immunodeficiency: 2 patients, hyper immunoglobulin E syndrome:1 patient, X-linked lymphoproliferative :1 patient, chronic granulomatous disease:1 patient). ITP was detected in 8 of 9 patients and AIHA was also detected in 6 patients. In four patients (LRBA deficiency: 2 patients, hyper IgE syndrome:1 patient and CGD:1patient), both ITP and AIHA were observed. Immunosuppressive therapy with steroid, cyclosporine, mycophenolate mofetyl and intravenous immunoglobulin were given to all patients. Bone marrow transplantation was performed to the four patients. However, five patients died because of immunodeficiency.
Results: There is a paradoxal situation between PID and autoimmunity. The reduction of central and peripheral tolerance is held responsible for autoimmunity in PID.
Summary/Conclusions: As a conclusion, we wanted to point out autoimmune cytopenias in patients with PID and the requirement of multidisciplinary approach for treatment.

PB1757

HEAVY METAL LEVELS IN PATIENTS WITH FANCONI APLASTIC ANEMIA

T. Bayhan[1,*], O. Erdem[2], S. Unal[1], F. Gumruk[1], S. Cetinkaya[2], E. Cirak[3], I. Eker[4]
[1]Division of Pediatric Hematology, Hacettepe University, [2]Department of Pharmaceutical Toxicology, University of Health Sciences, [3]Pharmacoligist, Retired, Ankara, [4]Division of Pediatric Hematology, University of Afyon, Afyon, Turkey

Background: Fanconi aplastic anemia (FAA) is a rare, autosomal recessively inherited bone marrow failure disorder. Various congenital anomalies may accompany disease and various complications including malignancy and endocrinopathies may develop during the course.
Aims: Heavy metal levels in patients with different chronic disorders have been investigated, however, up to our knowledge there is no literature data on the heavy metal levels in patients with FAA. Heavy metal levels in patients with different chronic disorders have been investigated, however, up to our knowledge there is no literature data on the heavy metal levels in patients with FAA.
Methods: Study was performed between July 2015 and April 2016 among patients with FAA and the results were compared with age and gender matched control group**.** Plasma copper (Cu), iron (Fe), zinc (Zn), and whole blood chromium (Cr), cobalt (Co), selenium (Se) levels were measured in patients with FAA.
Results: Total of 17 patients with FAA were included in the study. Median age was 9 years (1 – 30), female to male ratio was 8/9. One patient had undergone stem cell transplantation, four patients were transfusion dependent. When we compared patients with FAA and age/sex matched healthy group (16 volunteers) Cr and Cu levels were higher and Se level was lower in FAA group significantly (Table 1). However, all patients had chromium level within normal range, two patients with FAA and two volunteers had copper levels higher than the normal ranges (Table 2).

Table 1. Heavy metal levels in patients and control group.

	FAA	Control	*p*
Chromium (mcg/L) (2.8-45)	8.5 (6.3 – 26.2)	6.5 (4.2 – 13.5)	**0.09**
Cobalt (mcg/L) (0.5-3.9)	1.6 (0.09 – 3.2)	1.6 (1.1 – 3.3)	0.84
Copper (mcg/dL) (70-150)	111.2 (65.3 – 181.3)	80.7 (49.5 – 204.9)	**0.01**
Iron (mcg/dL) (50-150)	187.2 (119.7 – 391.2)	254.2 (91.7 – 353)	0.62
Selenium (mcg/L) (0-150)	46.4 (30.6 – 68.5)	65 (44 – 112)	**0.00 1**
Zinc (mcg/dL) (70-120)	86 (53 – 124)	77.1 (47.3 – 131)	0.34

Low	3	6
Normal	13	7
High	1	3

FAA; Fanconi aplastic anemia.

Summary/Conclusions: In our study we found chromium and cobalt levels higher in patients with FAA than control group. In-vitro studies have revealed that FAA cells are more sensitive to chromium toxicity. With larger number of patients chromium level and clinical association should be investigated in further studies. Lower Se level in patients with FAA may be related with oxidative stress in these patients.

PB1758

CLINICAL IMPACT OF AGE AND COMORBIDITY IN PNH PATIENTS

E. Colado[1,2,*], M. Morado Arias[2,3], A. Gaya Valls[2,4], M. López Rubio[2,5], B. Arrizabalaga Amuchastegui[2,6], E. Lavilla Rubira[2,7], E.J. Salido Fiérrez[2,8], S. de la Iglesia Iñigo[2,9], P.A. Urquía Plazaola[2,10], I. Jarque Ramos[2,11], Á. Urbano Ispizua[2,4], A.M. Villegas Martínez[2,12]
[1]Hematología, Hospital Universitario Central de Asturias, Oviedo, [2]Grupo Español de Hemoglobinuria Nocturna, Sociedad Española de Hematología y Hemoterapia, [3]Hematología, Hospital Universitario La Paz, Madrid, [4]Hematología, Hospital Clinic, Barcelona, [5]Hematología, Hospital Universitario Príncipe de Asturias, Madrid, [6]Hospital Universitario Cruces, Bilbao, [7]Hospital Universitario Lucus Augusti, Lugo, [8]Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, [9]Hospital Universitario de Gran Canaria, Las Palmas, [10]Hospital Universitario Donostia, San Sebastián, [11]Hospital Universitario La Fé, Valencia, [12]Hospital Clínico San Carlos, Madrid, Spain

Background: PNH is an ultra-rare disorder affecting mainly young adults, but can be diagnosed in geriatric population. Comorbitidy is more prevalent in general geriatric population and can either hamper diagnostic evaluation or increase the complexity of PNH patient care.
Aims: To identify geriatric-age PNH in Spanish PNH registry. To study the clinical characteristics at diagnosis and evolution of geriatric-age PNH and compare them to non-geriatric PNH population. To analyse the impact of both age and prognosis in the PNH setting. To evaluate the use of eculizumab in geriatric age patients.
Methods: In a multicentric retrospective study, Cumulative Illness Rating Scale for Geriatrics (CIRS-G) and clinical and biological variables have been collected from a Spanish PNH Group patient cohort. Statistical analysis was performed using GraphPad Prism v5 (La Jolla, CA).
Results: 44 patients from 11 centres in Spain have been included up to date. 8 patients (17,8%) were diagnosed in geriatric age (equal or older than 65 years) (Age range for the complete cohort: 17-83 years) and 9 patients presented with high comorbidity, arbitrary defined as CIRS-G score >10. (Range for the complete cohort: 3-13) Age and comorbidity were poorly correlated (p= 0.0187, R-square 0.15) No differences in clinical presentation (Classic, PNH in the setting of another bone marrow failure syndrome or Subclinical PHN or high disease activity) when stratifying by age or comorbidity were observed. 4 patients had a concomitant myeloid clonal disorder (3 myelodisplastic syndrome and 1 myeloproliferative neoplasm), 3 of them (75%) in geriatric age.
Median follow up was 7,2 years. Both age equal or older than 65 years and CIRS-G >10 were associated to poorer overall survival (HR: 0.0134 and 0.045 & p= 0.0015 and 0.0103 respectively). Regarding PNH with high disease activity, 18 patients were identified, 4 of them in geriatric age. In 2 of them (50%), Eculizumab was used, which contrasts with eculizumab use in younger patients (78,6% in the same indication) Regarding comorbitidy impact on eculizumab therapy outcome, 2 patients had CIRS-G score >10 and had similar overall survival as patients with lower comorbidity in this cohort.
Summary/Conclusions: Age and comorbidity are associated with poorer overall survival in PNH. Older age and comorbidity may not preclude the use of effective treatment in PNH patients, including those with high disease activity. Prospective evaluation of comorbidity in PNH patients, regardless of age is warranted.

PB1759

A RARE ASSOCIATION: EBSTEIN-BARR VIRUS ASSOCIATED LYMPHOPROLIFERATIVE DISORDER AND PURE RED CELL APLASIA

S. Berk[1,*], M. Günaltılı[2], S. Sadri[1], M. C. Ar[1], T. Soysal[1]
[1]Haematology, [2]Internal Medicine, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Lymphoproliferative disorders (LPD) constitute a heterogeneous group of diseases related to expanding polyclonal or monoclonal lymphoid cells in the setting of immune dysfunction. Ebstein-Barr virus (EBV) has been implicated in the development of a wide range of B-cell LPD spectrum. EBV associated LPDs (EBV-LPD) are more commonly encountered after stem cell and organ transplantations.
Pure red cell aplasia (PRCA) is an uncommon disorder characterized by a severe normocytic anemia due to erythroblastopenia in an otherwise normal bone marrow. PRCA may be primary or develop secondary to viruses, autoimmune diseases, hematological malignancies, thymoma, solid tumors and drugs.
Aims: A case, who was diagnosed with EBV-LPD and developed PRCA during follow-up, is presented.
Methods: A 75-year-old woman with pain in upper and lower extremities applied to our center in February 2016. Her past medical history was unremarkable except for rheumatoid arthritis. On physical examination bilateral cervical, submandibular, axillary lymphadenopathies (LAP) and splenomegaly were detected. Laboratory tests revealed normochromic normocytic anemia, elevated serum lactate dehydrogenase and acute phase reactants. Positron emission tomography (PET) showed supra- and infradiaphragmatic malignant lymph nodes and splenic involvement. An excisional biopsy of cervical LAP was performed. Pathological examination showed CD20 (+) and CD30 (+) large B cells in the interfollicular area. EBV early RNA signals were ckecked by in-situ hybridization and viral transcripts were detected. Diagnosis of EBV-LPD was made. During diagnostic work-up deepening of anemia with reticulocytopenia, increased transfusion requirement and inadequate response to transfusion necessitated a bone marrow aspiration and biopsy. Pathological examination of the bone marrow was compatible with PRCA. Parvovirus IgM and DNA was negative; IgG was found to be positive. Because of the lack of response to steroids, Rituximab was given (375 mg/m2, weekly). Anemia and patient's clinical condition improved after 8 weeks of treatment.
Results: In the pathogenesis of LPD polyclonal lymphoid response to an antigenic trigger is thought to be followed by development of monoclonal neoplastic diseases. In our case, this trigger was thought to be EBV as it is known as one of the main causative agents for LPD in the literature. Clinical complaints and physical examination findings are common among all patients and frequently not leading to a definitive diagnosis in most of them as it is the case in our patient. Compared to the strong association of secondary PRCA with parvovirus B19 its association with EBV is rare. PRCA can develop before the diagnosis, during the course and after the remission of LPD. In our case we observed PRCA in the follow-up period of EBV-LPD.
Summary/Conclusions: On the basis of EBV-LPD being more common in transplant setting our case was thought to be unique due to the absence of transplantation or immunosuppression history. This case report points out to the possibility of oexistence of two rare diseases, EBV-LPD and PRCA.

Businco, Cagliari, [16]Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, [17]Ospedale C. G. Mazzoni, Ascoli Piceno, Italy

Background: Patients affected by chronic lymphocytic leukemia (CLL) that have trisomy 12 (+12) on FISH analysis have unique clinical and biological features. In a prior analysis (*Autore F, ASH 2016*) of 487 patients with +12 compared to 816 patients with negative FISH, patients with +12 had a significantly higher prevalence of elevated LDH, β-2-microglobulin, ZAP70 positivity, CD38 positivity, CD49d positivity and unmutated IGHV as compared to patients with negative FISH. They also showed shorter progression free survival (PFS), treatment free survival (TFS) and overall survival (OS).
Aims: To identify clinical and laboratory features that predict disease progression, time to treatment and survival in treatment-naive patients with +12 CLL.
Methods: This study included 487 treatment-naive patients with +12 CLL from 16 academic centres, diagnosed between January 2000 and July 2016. A cohort of 250 patients with +12 CLL followed at a single US institution was used as external validation. Data were summarized as medians and 25th and 75th percentiles. Chi-square test or Fisher's exact test were used to compare categorical variables, while Wilcoxon-Mann-Whitney-Test was applied for continuous variables. The survival analysis was based on the Kaplan-Meier method and the log-rank test was used to compare survival curves. A Cox model was used for multivariate analysis of the impact of different factors on survival. P values lower than 0.05 were considered statistically significant (STATA 12.0) and reported as two-sided. We analysed also CLL-specific survival considering events deaths due to the haematological disease.

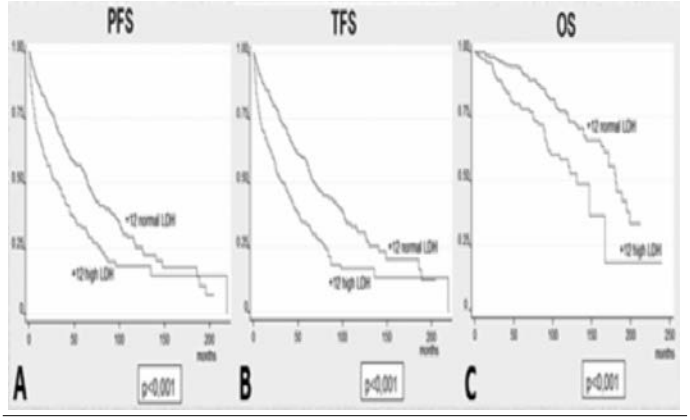

Figure 1.

Results: Parameters associated with shorter PFS, TFS, OS and CLL-specific survival on univariate analysis were IGHV, LDH, β-2-microglobulin and Rai stage; age, ZAP70 and CD38 associated with OS only; on multivariate analysis, high LDH and unmutated IGHV remained significantly with shorter PFS, TFS, OS and CLL-specific survival, higher Rai stage with shorter PFS and elevated β-2-microglobulin with shorter OS. Considering interestingly the association of a simple and new laboratory parameter such as LDH to the outcomes, confirmed on multivariate analyses for PFS (hazard ratio [HR] 1.55, 95% confidence interval [CI] 1.2 to 2.1; p=0.004), TFS (HR 1.62, 95% CI 1.2-2.2; p=0.002), OS (HR 1.69, 95% CI 1.1-2.7; p=0.034) and CLL-specific survival (HR 3.86, 95% CI 2.0-7.5; p<0.001), we divided our +12 CLL cohort according to LDH levels available at diagnosis: 103 patients showed LDH levels above the normal limit and 184 within normal range. Patients with high LDH levels showed shorter PFS (30 months *vs* 65 months, p<0.001; Figure 1A), TFS (33 months *vs* 69 months, p<0.001; Figure 1B), OS (131 months *vs* 181 months, p<0.001; Figure 1C) and CLL-specific survival with a rate of attributable mortality of 29% *vs* 11% (p<0.001). In the validation cohort, 104 patients had high LDH levels and 145 patients had normal LDH levels; factors significantly associated with PFS and TFS on univariate analysis were LDH, β-2-microglobulin, Rai stage and ZAP70; LDH, β-2-microglobulin and age associated with OS. On multivariate analysis high LDH was the sole parameter significantly associated with all shorter outcomes, along with elevated β-2-microglobulin, which associated with shorter OS.
Summary/Conclusions: Our study on 487 patients with +12 CLL and the analysis on 250 patients of the validation cohort showed that patients with +12 and elevated LDH have shorter PFS, TFS, OS and CLL-specific survival.

THE PERCENTAGE OF CELLS WITH ABNORMALITIES IN FISH STUDIES CONFERS PROGNOSTIC INFORMATION IN CLL PATIENTS

I. González-Gascón Y Marín[1,*], M. Hernández-Sánchez[2], A.E. Rodriguez-Vicente[2], C.C. Muñoz Novas[1], M. S. Infante[1], C. Heras[1], M.A. Foncillas[1], K. Marín[1], J.M. Hernández Rivas[2], J.Á. Hernández[1]
[1]Hospital Universitario Infanta Leonor, MADRID, [2]IBSAL, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Genomic aberrations detected by FISH have become one of the most important and widely used prognostic factor for chronic lymphocytic leukemia (CLL) patients. In addition several publications have described that patients with a higher percentage of abnormal nuclei have a worse outcome.
Aims: To analyze the effect of the percentage of abnormal nuclei detected by FISH (13q deletion (13q-), 11q deletion (11q-), 17p deletion (17p-) and trisomy 12 (+12)) in overall survival (OS) and time to first treatment (TTFT).
Methods: We studied a non-selected cohort of 650 consecutive CLL cases from a local database with a median follow up time of 50 months (0-346). The cut-off point for the percentage of abnormal nuclei for each alteration was detected by dividing the variable into deciles, and selecting the most efficient cut-point, and based on previous publications.
Results: FISH detected aberrations in 68% of the cases (442/650). The most frequent abnormality was 13q-, observed in 302 patients (47%), but as a sole alteration in 212 cases, followed by +12 (106 patients, 16%), 11q- (83 patients, 13%), and 17p- (33 patients, 5%). As expected, the group of patients with 13q- as a sole abnormality was the one with the better OS (195 months) followed by the group of patients with normal FISH (160 months), +12 (124 months), 11q- (56 months) and 17p- (46 months), consistent with the Dohner hierarchical classification (Döhner H *et al.* NEJM 2000). Similar results were observed in TTFT: 13q- as sole abnormality (106 months), normal FISH (112 months), +12 (29 months), 11q- (10 months), 17p- (10 months). The best predictive cut-off point that divided patients according to its prognosis was different for each alteration. We confirmed that a high percentage of cells carrying the deletion is associated with a significantly worse TTFT in cases with 17p, 13q, and 11q deletions, and a significantly shorter OS in cases with 17p deletion. We observed a similar trend for OS in cases with 13q and 11q deletions, probably not significant because of the low number of patients included, compared to previous studies. We observed the same trend in patients with +12. The Table 1 summarizes these findings. Probably with a higher number of cases and a longer follow up, it could have also been possible to reach statistically significant differences in the subgroups in which it was not objected.

Table 1.

FISH abnormality	Number of cases	Overall survival (months)	P	Time to first treatment (months)	P
13q-(sole abnormality) < 75% ≥ 75%	212	195 (CI 95%, 162-228) 275 (CI 95%, not reached) 157 (CI 95%, 126-188)	0.06	106 (CI 95%, 69-143) 122 (CI 95%, 91-153) 40 (CI 95%, 16-64)	0.001
11q- < 40% ≥ 40%	83	56 (CI 95%, 33-79) 71 (CI 95%, 50-92) 39 (CI 95%, 24-53)	0.08	10 (CI 95%, 3-17) 37 (CI 95%, 26-48) 7 (CI 95%, 4-9)	0.025
17p- < 20% ≥ 20%	33	46 (CI 95%, 24-68) 65 (CI 95%, 50-80) 32 (CI 95%, 22-41)	0.02	10 (CI 95%, 1-18) 40 (CI 95%, 16-63) 5 (CI 95%, 0-12)	0.026
+12 < 60% ≥ 60%	106	124 (CI 95%, 31-164) 130 (CI 95%, 66-194) 98 (CI 95%, 54-141)	0.9	29 (CI 95%, 18-40) 38 (CI 95%, 15-61) 24 (CI 95%, 11-36)	0.085

Summary/Conclusions: Not only the type of cytogenetic abnormality but also the percentage of abnormal nuclei detected by FISH are important factors in the prognosis of CLL patients.

PB1762

METHYLATION STATUS OF RAD21 GENE IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Ioannidou[1,*], S. Zachaki[2], M. Karakosta[1], A. Daraki[1], P. Roussou[3], K. Manola[1]
[1]Laboratory of Health Physics, Radiobiology & Cytogenetics, National Center for Scientific Research (NCSR) "Demokritos", [2]Genesis Genoma Lab, Genetic Diagnosis, Clinic Genetics and Research, [3]Hematology Unit, Third University Department of Medicine, "Sotiria" General Hospital, ATHENS, Greece

Background: Chronic Lymphocytic Leukemia (CLL) pathogenetic mechanisms have not been fully elucidated yet. However, genetic and epigenetic alterations seem to be involved in the pathogenesis and extensive clinical heterogeneity of the disease. DNA methylation in CpG sites of a gene promoter, which may affect the chromatin structure as well as gene transcriptional activity, is a crucial epigenetic modification in CLL. *RAD21* gene is involved in DNA repair and its encoded product acts as basic subunit of the Cohesin protein complex that regulates the cohesion and proper separation of sister chromatids during mitosis or meiosis.
Aims: We investigated the methylation status of *RAD21* gene promoter and its possible implication in CLL pathogenesis and the formation of CLL cytogenetic aberrations.
Methods: The study included 105 CLL patients and 17 healthy donors (controls)**.** Total genomic DNA extraction was performed from bone marrow or peripheral blood samples of all patients and controls. Methylation analysis of *RAD21* gene promoter was carried out using the new techology of MethylScreen™ in the CFX96Biorad Real-Time PCR system. For this purpose, we used EpiTect Methyl II PCR Assay which enables us to calculate the methylated and unmethylated fraction after simultaneous digestions with specific restriction enzymes. Karyotypic analysis was performed on unstimulated and stimulated with CpG-oligonucleotide DSP-30 bone marrow cells of CLL patients. FISH analysis was carried out using the commercial CLL set probes for detection of the most common abnormalities of the disease including deletions of 17p13 (TP53), 11q22.3 (ATM) and 13q14.3/13q34.3 (D13S319/13q34) regions and trisomy 12 (CEP 12).
Results: Among the105 CLL patients, 21 patients exhibited a normal karyotype also confirmed by FISH and 84 patients showed chromosome abnormalities detected by karyotypic or/and FISH analysis. Methylation study was successful in all healthy donors and in 101 out of 105 CLL patients. All healthy donors had non-methylated *RAD21* gene promoter. On the contrary, 25.74% (26/101) of CLL patients carried >10% cells with methylated CpG islands in *RAD21* promoter, which was significantly increased compared to controls (p=0.039, χ^2=4.25, *df*=1). RAD21 methylated cell fraction varied among patients. More specifically, 9.9% of patients (10/101) showed 11-50% methylation rate, 10.89% (11/101) 51-89% and 4.95% (5/101) showed high methylation rate score, >90% of the analyzed cells. Stratification of patients according to cytogenetic findings showed that the promoter of *RAD21* was methylated in 28.57% of patients (6/21) with normal karyotypes and 25% of patients (20/80) with abnormal karyotypes. In detail, methylation in *RAD21* promoter was present in 33.33% of patients (5/15) with abn(14q32), in 33.33% (4/12) with abn(8), in 31.25% (5/16) with -17/del(17p), in 27.78% (5/18) with trisomy 12, in 25.81% (8/31) with del(13q), in 20% (2/10) with del(6q) and in 12.5% (2/16) with del(11q). Based on karyotypic complexity, *RAD21* promoter was methylated in 18.18% (4/22) of patients with a single chromosome aberration, 26.09% (6/23) with two chromosome aberrations and 25.71% (9/35) of patients with complex karyotype (≥3 aberrations).
Summary/Conclusions: Methylation of *RAD21* gene promoter, which leads to transcriptional inactivation and consequently inhibition of *RAD21* expression, seems to be implicated in CLL pathogenesis and the formation of specific chromosome aberrations. Clarification of the epigenetic landscape of CLL may help in the design of new targeted therapeutic agents.

PB1763

ROLE OF KEAP1-NRF2 PATHWAY GENETIC VARIABILITY IN THE SUSCEPTIBILITY AND PROGNOSIS OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

S. Marini[1,*], J. Carda[1,2,3], J. Antunes[2], A. Ribeiro[1,2,3], R. Tenreiro[1], L. Ruzickova[1], R. Alves[2,3,4], J. Jorge[2,3], A. Pires[2,3], L. Jorge[5], G. Marques[5], L. Ribeiro[1], A. Gonçalves[2,3,4], A.B. Sarmento Ribeiro[1,2,3,4]
[1]Hematology Department, Coimbra University Hospital - CHUC, [2]Medicine Department, Faculty of Medicine of Coimbra University , [3]Center of Investigation in Environment, Genetics and Oncobiology, [4]CNC-IBILI - Coimbra University, [5]Pathology Department, Coimbra University Hospital - CHUC, Coimbra, Portugal

Background: Chronic lymphocytic leukemia (CLL) is the most prevalent leukemia in the western adult population. Although advanced age, white ancestry, and family history of hematologic malignancies are risk factors, the etiology of CLL still unknown. One of the mechanisms associated with the development of this pathology is related to the oxidative stress (OS) resulting from an imbalance between the production of reactive oxygen species (ROS) and their disposal by the antioxidant defenses. The nuclear factor erythroid 2-like gene - type 2 (*NFE2L2*) and its suppressor, the Kelch-like ECH-associated protein 1 (*KEAP1*) gene, plays a central role in ROS balance. Changes in these genes, whether due to somatic mutations or genetic variants (SNPs), have been associated with some hematological diseases. However, the role of *NFE2L2* and *KEAP1* genes polymorphisms in susceptibility and prognosis of CLL is not studied.
Aims: To assess the role of two SNPs in the NFE2L2 and KEAP1 genes on CLL susceptibility, their influence on prognosis/survival, and their correlation with clinical and laboratory characteristics of patients.
Methods: Genetic variants rs13001694 (NFE2L2) and rs11085735 (KEAP1) were genotyped by tetra-primers-AMRS-PCR in 176 patients with CLL and 261 controls. The role of these genes polymorphisms in CLL susceptibility and their association with clinical and laboratory characteristics as well as with therapy response was assessed by logistic regression analysis and/or by Fisher's exact test. The influence on prognosis and survival was performed through Kaplan-Meier curves by estimating the progression free survival (PFS) and the overall survival (OS).
Results: The results showed that individuals with the GG genotype (NFE2L2) are at higher risk of developing CLL [Odds ratio (OR): 2.032; 95% confidence interval (CI): 1,234-3,351; P=0.004]. In addition, the genotypic profile (GP) GG / CC (NFE2L2 / KEAP1) is a risk factor (OR: 2.186; 95% CI: 1.279-3.744; p=0.003) for the development of CLL while the AA / CC profile constitutes a protective factor (OR: 0.634, 95% CI: 0.407-0.984, p=0.037). In contrast, patients with genotype AG (NFE2L2) and/or CC (KEAP1) had a higher rate of complete response to rituximab therapy regimens (NFE2L2 AG: OR 1.6, 95% CI 1.063-3.933, p=0.037; KEAP1 CC, OR 1.2, 95% CI 1.041-3.477, p=0.045, NFE2L2 / KEAP1 AG / CC: OR 1.9, 95% CI, 1.843-4.485, p=0.017) and with fludarabine (NFE2L2 / KEAP1 AG / CC: OR 1.5, 95% CI, 1.119-3.887, p=0.026). Finally, the overall survival of CLL patients appears to be influenced by the genotypic profile of NFE2L2 / KEAP1 [GP AG / AC patients have a lower mean survival (72.5±13.8 months) than patients with other GPs (139.4±10.2 months, p=0.037)], while progression-free survival seems to be influenced by the KEAP1 genotype [patients with CC genotype have a longer mean survival (198.0±13.6 months) than patients with AA and AC genotypes (85.3±13.4 months; P=0.022)].
Summary/Conclusions: This study suggest that genetic polymorphisms in *NFE2L2* and *KEAP1* genes might be risk factors for CLL development and may constitute novel genetic markers for therapy response (namely regimes with rituximab and fludarabine) as well as prognostic markers, by influencing overall survival and progression free survival in CLL patients.
The authors declare no conflicts of interest.

EVALUATION OF BASAL CHROMOSOME ABERRATIONS AND MICRONUCLEUS FREQUENCY IN UNTREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA AND THEIR ASSOCIATION WITH PROGNOSTIC MARKERS

M. Palmitelli[1,*], C. Stanganelli[2], P. Dos Santos[3], B. Brizuela[3], F. Stella[3], R. Bezares[4], I. Slavutsky[3], M. González Cid[1]
[1]Laboratorio de Mutagénesis, Instituto de Medicina Experimental, CONICET-Academia Nacional de Medicina, [2]División Patología Molecular, Instituto de Investigaciones Hematológicas, Academia Nacional de Medicina, [3]Laboratorio de Genética de Neoplasias Linfoides, Instituto de Medicina Experimental, CONICET-Academia Nacional de Medicina, [4]Servicio de Hematología, Htal. Teodoro Álvarez, Buenos Aires, Argentina

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease, with variable clinical presentation and evolution. Two major subtypes can be distinguished, mutated (M) and unmutated (UM), characterized respectively by a high or low number of somatic hypermutations in the variable region of immunoglobulin genes and different outcome. Cytogenetic and FISH (fluorescence *in situ* hybridization) studies have proved to be important tools in the biologic characterization of this disease, allowing the identification of distinct risk groups. Genomic instability involves a process prone to the accumulation of chromosome alteration in somatic cells and is a major driving force of tumorigenesis. The analysis of chromosome aberrations (CA) and micronucleus (MN) represent different forms to evaluate genomic instability.
Aims: In this study, we have analyzed the basal frequency of CA and MN in untreated CLL patients. Results were evaluated in relation to different prognostic factors.
Methods: A total of 67 untreated CLL patients (36 males; mean age: 66.6 years; range: 42-83 years; Rai stage: 0: 27%; I-II: 59%; III-IV: 14%), and 6 normal controls, were studied. Chromosome analysis was performed on stimulated peripheral blood lymphocytes cultures. For each patient, CAs were evaluated on 50 cells stained with 10% Giemsa and the MN frequency was assessed on 250 interphase nuclei. FISH analysis was performed using the CLL panel according to manufacturer´s protocol. *IGHV* (immunoglobulin heavy chain variable region) mutational status was analyzed by RT-PCR and bi-directional sequencing. The study was approved by the local Ethics Committee. All individuals provided their informed written consent.

Results: An increased number of CAs, including chromatid breaks and dicentrics, in CLL patients (6.59±5.3%) compared to controls (0.25±0.04%) (p=0.021) was observed. A tendency to increased CA frequency in cases with abnormal (8.18±6.1%) compared to normal karyotypes (5.67±4.4%) (p=0.08) was also found. The analysis taking into account FISH risk groups showed a higher frequency of CA in patients with deletions 11q22 and/or 17p13 associated to poor outcome (8.54±6.1%), than those with no alterations or 13q14 deletion related to a better outcome (5.64±3.9%) and cases with +12 with an intermediate prognosis (4.54±3.5%). By MN analysis, an increased frequency in CLL patients (2.81±1.5%) compared to controls (0.67±0.3%) (p=0.0001) was found. Patients with +12 presented the highest percentage of MN compared to the other two groups (~1.3-fold), indicating the aneugenic effect of this alteration. The evaluation according to the *IGHV* mutational status showed similar frequencies for CAs and MN in M-CLL (6.2±5.2% and 2.82±4.9%, respectively) and UM-CLL (6.2±5.8% and 2.7±1.3%, respectively). No association between CA and MN frequencies and clinical parameters was found.
Summary/Conclusions: Our results confirm the presence of basal genomic instability in untreated CLL patients as measured by both CA and MN techniques. To our knowledge, this is the first analysis of these parameters taking into account prognostic factors of the disease. Cases with deletions 11q22 and/or 17p13 had the highest value of CA and those with +12 showed the highest frequency of MN, reflecting different mechanism of DNA damage.

PB1765

B CELLS RESISTANT TO CD20 MONOCLONAL ANTIBODIES DISPLAY SPECIFIC ALTERATIONS IN GENE EXPRESSION PROFILE

A. Ledererová[1,*], V. Kozlová[1], V. Vakulová[1], M. Doubek[1,2], J. Mayer[1,2], Š. Pospíšilová[1,2], M. Šmída[1,2]
[1]Central European Institute of Technology (CEITEC), Masaryk University, [2]Department of Internal Medicine - Hematology and Oncology, Medical Faculty of Masaryk University and University Hospital Brno, Brno, Czech Republic

Background: CD20 monoclonal antibodies (mAb) are a standard of care for B-lymphoid malignancies. Yet, their clinical efficacy is quite variable and many patients relapse, while their malignant cells express very low density of CD20 on the cell surface. In spite of being used for 20 years as a therapy target, little is known about the biology and regulation of CD20 inside the cell.
Aims: The aim of this proposal was to investigate the intracellular mechanisms regulating expression of CD20 antigen.
Methods: Diverse cell and molecular biology techniques were used, including flow cytometry analysis, real-time PCR and RNA sequencing.
Results: We show that treatment of B cells with different CD20 mAbs initiates a signaling cascade within the cells that is partially distinct from classical B-cell receptor signaling machinery and does not involve BCR proximal proteins. Importantly, it results in a prompt downregulation of CD20 expression. Through chronic exposure to gradually increasing doses of monoclonal antibodies, we have generated cell lines that are resistant to additional treatment with mAb. Notably, these cells are resistant also to any other of the available anti-CD20 antibodies even at very high concentrations as shown by dose-response experiments. This resistance is sustained for long period and maintained even upon many rounds of cell passages. We could confirm that these cells have downregulated CD20 protein from the cell surface and that this effect was not just due to its internalization. Instead, we detected a defect in CD20 transcription as measured by quantitative real-time PCR. Flow cytometry analysis of other surface markers showed a strong upregulation of CD55 and CD59, known inhibitors of complement activation. The combination of CD20 loss together with the increase of CD55 and CD59 is responsible for the complete resistance to the mAbs. We have then analyzed changes in overall gene expressions by performing RNA sequencing and quantitative real-time PCR. We have identified several interesting genes whose expression was altered in our resistant cells when compared to their control counterparts. Among the most interesting hits was a strong downregulation of the transcription factor NFkB, which was expressed more than 10-fold lower in the rituximab or ofatumumab resistant cells. We could confirm this result in multiple independent experiments. We have postulated that anti-CD20-triggered signaling results in the inactivation of NFkB and this may lead to the block in CD20 transcription. To confirm our hypothesis, we have treated the cells with phorbol ester PMA, which nonspecifically activates NFkB. Indeed, cells treated with PMA managed to rapidly upregulate CD20 on their cell surface.
Summary/Conclusions: In summary, CD20 triggering by therapeutic mAbs initiates complex intracellular changes that result in downmodulation of CD20 expression. Further analysis of detailed intracellular mechanisms regulating CD20 is warranted in order to propose novel interrogation nodes that might modulate CD20 surface density and thereby enhance the therapeutic potential of CD20 monoclonal antibodies.

DIFFERENTIAL EXPRESSION PATTERNS OF CHEMOKINE RECEPTORS IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Petrackova[1], G. Manukyan[1,2], T. Papajik[3], V. Kraiczova[1], R. Fillerova[1], Z. Mikulkova[1], G. Gabcova[1], R. Urbanova[3], P. Turcsanyi[3], P. Ryznerova[3], L. Kruzova[3], E. Kriegova[1,*]
[1]Department of Immunology, Palacky University Olomouc, Olomouc, Czech Republic, [2]Laboratory of Molecular and Cellular Immunology, Institute of Molecular Biology NAS RA, Yerevan, Armenia, [3]Department of Hemato-Oncology, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic

Background: Chemokines and their receptors are involved in the regulation of cell recruitment, survival, proliferation, and trafficking, all these processes crucial in the pathogenesis of chronic lymphocytic leukemia (CLL). Comprehensive profiling of chemokine receptors in CLL and its subgroups according prognostic relevance is missing.
Aims: To characterize the chemokine expression pattern in CLL patients and subgroups according to clinical course and cytogenetic aberrations.
Methods: We studied the gene expression pattern of 16 canonical and 4 atypical chemokine receptors in peripheral blood mononuclear cells (PBMC) of CLL patients (n=88) and healthy subjects (n=34) by using SmartChip quantitative RT-PCR (WaferGen Bio-systems). The expression of CXCR3, CXCR4, CXCR5, CXCR7, and CCR7 was confirmed by flow cytometry.
Results: Among deregulated receptors, 5 receptors (CCR7, CCR10, CXCR3, CXCR4, CXCR5) were up-regulated and 9 receptors (CCR2-CCR6, CCR8, CCRL2, CXCR1, CXCR2) down-regulated in CLL; the expression of others did not differ between CLL and controls (P>0.05). In patients with del(17p) associated with a poor prognosis, we observed higher mRNA levels of CXCR6, CXCR7 and CCR10 comparing to del(13q). On protein level, the percentage of neoplastic B cells positive for CXCR4, CXCR5, and CCR7 was higher and percentage of CXCR7 lower than on normal B cells (P<0.05). In patients with CLL a marked increase in MFI of CXCR4 (P<0.001) and CCR7 (P<0.001) on CLL cells was detected comparing to healthy subjects.
Summary/Conclusions: Our results provide a complete picture of expression patterns of chemokine receptors in PBMC of CLL patients and prognostically relevant subgroups. Further studies are needed to clarify how chemokine receptor network affects neoplastic development and progression.

RESIDUAL SERUM CONCENTRATIONS OF RITUXIMAB ARE ASSOCIATED WITH RELAPSE RISK IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Tempescul[1,*], C. Berthou[1], H. Saad[1], V. Olivier[1], B. Boutahar[2], M. Zdrenghea[3], Y. Renaudineau[2], C. Bagacean[2]
[1]Clinical Hematology, [2]Laboratory of Immunology, Teaching Hospital Brest, Brest, France, [3]Clinical Hematology, Oncology Institute "Ion Chiricuta", Cluj-Napoca, Romania

Background: Rituximab is an anti-CD20 chimeric monoclonal antibody approved in first-line treatment of patients with chronic lymphocytic leukemia (CLL), in association with chemotherapy. Rituximab displays a time-dependant pharmacokinetic with a high variability between patients that is primarily related to target mediated elimination.
Aims: Rituximab pharmacokinetics has been associated with clinical response but there is no data on its association with patients' evolution after immunochemotherapy, which is the aim of the present study.
Methods: Residual serum concentrations of rituximab were determined by an enzyme-linked immunosorbent assay (ELISA) for 35 CLL patients before each infusion, administrated every 28 days at T0, T1, T2, T3, T4, T5. Response and relapse criteria were evaluated according to the International Workshop on Chronic Lymphocytic Leukemia guidelines.
Results: Patients were assigned to two groups related to time to relapse. The first group (n=7), had an early relapse in less than 3 years, the second group (n=28), in more than 3 years. A lower residual serum rituximab concentration was observed in patients with an early relapse and statistical significance was reached for the values obtained after the 3rd cycle (T3) (p=0.02). Concerning the area under the curve (AUC), the difference was significant across all the cycles, an early relapse being associated with a low AUC (AUC_{mean}A=1.28 ±1.01 mg/L*day, AUC_{mean}B=2.79±1.93 mg/L*day, p=0.02). Additionally, the residual rituximab serum concentration between T2 and T5, superior at 70µg/ml, is associated with a long response time, with a sensibility of 100% and a specificity of 52%. Low residual serum rituximab concentrations in the early relapse group were associated with a higher expression of CD38 and a more frequent administration of the chemotherapy rituximab-bendamustine than rituximab-fludarabine-cyclophosphamide. On the other hand, there was no association with age, sex, cytogenetics, tumour burden or with FCGR3A-158VF polymorphism.
Summary/Conclusions: In conclusion, serum residual rituximab concentration in patients with CLL has an impact on clinical evolution after treatment. This study provides data that sustains the need of rituximab serum concentration adaptation in certain CLL patients, in order to reduce relapse risk.

ACTIVITY OF THE CD19 ANTIBODY MOR208 IN COMBINATION WITH IBRUTINIB, IDELALISIB OR VENETOCLAX *IN VITRO*

R. Boxhammer[1,*], B. Bauer[1], S. Steidl[1], J. Endell[1]
[1]Pharmacology, MorphoSys AG, Planegg, Germany

Background: CD19 is broadly expressed across B-cell malignancies, including chronic lymphocytic leukemia (CLL). MOR208 is an Fc-enhanced CD19 antibody mediating potent antibody-dependent cellular cytotoxicity (ADCC), antibody-dependent cellular phagocytosis (ADCP) and direct cytotoxicity. Single agent MOR208 has shown promising activity in clinical studies.
Aims: We investigated the *in vitro* cytotoxicity of MOR208 when combined with the tyrosine kinase inhibitors (TKIs), ibrutinib and idelalisib, and the BCL-2 inhibitor, venetoclax.

Methods: The CLL cell line MEC-1 was treated with 0.3–10 µM ibrutinib, idelalisib or DMSO (control) for 7 days or 3–10 µM venetoclax or DMSO for 24 hours. Inhibition of proliferation, cytotoxicity and impact on CD19 expression were then assessed. ADCC assays with MOR208 incorporated a fixed number of primary human natural killer cells from healthy volunteers as effector cells. By contrast, the number of target cells was reduced according to antiproliferative or cytotoxic effects of the TKIs or venetoclax. Dose-dependent ADCC activity of MOR208 was analyzed by flow cytometry. Cytotoxic effects were studied in at least three independent experiments.
Results: Ibrutinib and idelalisib induced only moderate direct cytotoxicity on MEC-1 target cells but had strong antiproliferative effects. In contrast, venetoclax induced strong cytotoxicity on MEC-1 target cells within 24 hours. Both effects led to reduced tumor target cell numbers in the subsequent ADCC assays. CD19 expression was largely unaffected by all three drugs. The addition of MOR208 to ibrutinib, idelalisib or venetoclax treated target cells resulted in enhanced maximum ADCC when compared with single agent MOR208. EC50 values remained unaltered in TKI or venetoclax treated conditions compared with the DMSO control. Calculations according to Chou-Talalay yielded combination indices below 1 for all three drugs, thus confirming synergistic activity.
Summary/Conclusions: The cytotoxic effect of MOR208 was synergistically enhanced when combined with ibrutinib, idelalisib or venetoclax *in vitro*. These promising data provide a strong rationale for combination of MOR208 with these agents in future clinical trials.

PB1769

LYMPHOCYTE EXHAUSTION AND THE NATURAL HISTORY OF CHRONIC LYMPHOCYTIC LEUKEMIA – FRIENDS OR FOES?

E. Grywalska[1,*], J. Rolinski[1], M. Pasiarski[2], M. Mielnik[1], E. Fitas[1], S. Gozdz[3]
[1]Department of Clinical Immunology and Immunotherapy, Medical University of Lublin, Lublin, [2]Clinic of Hematology and Bone Marrow Transplantation, [3]Clinic of Clinical Oncology, Holycross Cancer Center, Jan Kochanowski University, Kielce, Poland

Background: Chronic lymphocytic leukemia (CLL) is a disease characterized by the accumulation of morphologically mature monoclonal lymphocytes B with CD19+/CD5+/CD23+ phenotype in lymphoid tissue, peripheral blood and bone marrow. The course of CLL is chronic by default. Of note, however, is its heterogeneity. Programmed cell death protein 1 and its ligand 1 (PD-1, PD-L1) as well as CD200 and CD200 receptor (CD200R) are major inhibitory receptors regulating T cell exhaustion, *i.e.* a state of T cell dysfunction. The role of lymphocyte exhaustion in the natural history of CLL is still a matter of discussion.
Aims: The aim of this study was to determine the percentages and absolute numbers of exhausted lymphocytes B and T in peripheral blood and bone marrow of CLL patients. Moreover, we analyzed relationship between the number of PD-1-positive, PD-L1-positive, CD200-positive, and CD200R-positive lymphocytes and established prognostic factors in CLL.
Methods: The study included 60 untreated patients with CLL and 20 healthy subjects. The immunophenotype of peripheral blood mononuclear cells (in both groups) and bone marrow cells (solely in the CLL group) was determined by means of flow cytometry.
Results: Patients with CLL showed higher frequencies and absolute number of exhausted B lymphocytes CD19+PD-1+ ($p<0.0001$), CD19+PD-L1+ ($p<0.0001$), CD19+CD200+ ($p<0.0001$) and CD19+CD200R+ ($p<0.0001$), as well as higher frequencies and absolute number of exhausted T helper lymphocytes CD4+PD-1+ ($p=0.0021$), CD4+PD-L1+ ($p=0.0032$), CD4+CD200+ ($p=0.0027$), CD4+CD200R+ ($p=0.0062$), and exhausted T cytotixic lymhocytes CD8+PD-1+ ($p=0.0036$), CD8+PD-L1+ ($p=0.0029$), CD8+CD200+ ($p=0.0038$), CD8+CD200R+ ($p=0.0073$) than the controls in the peripheral blood. Similar observations were done in the bone marrow samples ($p<0.0001$, $p<0.0001$, $p<0.0001$, $p<0.0001$, $p=0.0134$, $p=0.0183$, $p=0.0263$, $p=0.0169$, $p=0.0261$, $p=0.0362$, $p=0.0293$, and $p=0.0379$, respectively). Enhanced exhaustion of peripheral blood and bone marrow lymphocytes was associated with higher Rai stage, increased concentration of lactate dehydrogenase and beta-2 microglobulin, and more rapid progression of the disease. The number of lymphocytes B CD19+ZAP-70+ correlated positively with the number of CD19+PD-1+ B cells, CD4+PD-1+ T cells, and CD8+CD200+ T cells.
Summary/Conclusions: The study confirmed the association between unfavorable prognosis and high expression of exhaustion markers in CLL patients. Determination of PD-1+, PD-L1+, CD200+ and CD200R+ lymphocytes T and B constitutes valuable diagnostic tool, completing cytometric evaluation of CLL.

PB1770

HSP70 AND HSF1 GO HAND IN HAND AND HAVE A ROLE IN THE SURVIVAL OF CHRONIC LYMPHOCYTIC LEUKEMIA NEOPLASTIC B CELLS

F. Raggi[1,2], F. Federica[1,2], V. Martini[1,2], F. Severin[1,2], V. Trimarco[1,2], L. Martinello[1,2], A. Visentin[1,2], E. Scomazzon[1], S. Imbergamo[1], M. Facco[1,2], F. Piazza[1,2], G. Semenzato[1,2], L. Trentin[1,2,*]
[1]Dipartimento di Medicina, Università di Padova, [2]VIMM Istituto Veneto di Medicina Molecolare, Padova, Italy

Background: B-cell Chronic Lymphocytic Leukemia (CLL) is a neoplastic disorder characterized by the accumulation of clonal B cells in peripheral blood, bone marrow and lymphoid tissues. CLL is a clinically and biologically heterogeneous disease. As a consequence, novel biological and cytogenetic features have become increasingly important in predicting prognosis at the time of diagnosis and the research for molecules involved in apoptosis resistance and increased survival of neoplastic B cells is still ongoing.
Aims: We recently found that the Heat Shock Protein of 70kDa (HSP70) is overexpressed in Chronic Lymphocytic Leukemia (CLL) B cells. Considering the pro-survival role of HSP70 in cancer, we were aimed at characterizing this protein and its master regulator, the Heat Shock Factor 1 (HSF1), within the pathogenetic mechanisms leading to CLL.
Methods: HSP70 and HSF1 expression levels were evaluated by Western blotting (WB) analysis in leukemic and normal B cells. HSP70 and HSF1 protein levels were correlated to IGHV mutational status and ZAP70 protein expression in CLL patients. HSP70 and HSF1 levels were also analyzed in neoplastic cells obtained from patients undergoing Ibrutinib based regimen by WB analysis. Moreover, HSP70 and HSF1 localization was analyzed by subcellular protein fractionation followed by WB analysis. The effects of HSP70 and HSF1 inhibition (by Zafirlukast and Fisetin) were evaluated by Annexin V/Propidium Iodide flow cytometry test and WB analysis of PARP cleavage.
Results: We demonstrated that HSP70 and HSF1 are overexpressed in leukemic *vs* normal B cells and their expression levels correlate to poor prognosis in CLL. We also analyzed HSP70 and HSF1 levels in patients following *in vivo* Ibrutinib based regimen, observing a positive correlation between these two protein expression levels and moreover we observed that these two protein levels decreased after therapy. We found that at steady state both HSP70 and HSF1 are localized in the nucleus of CLL B cells. HSP70 and HSF1 inhibition was proved to be effective in inducing a dose-dependent *in vitro* apoptosis of CLL B cells.
Summary/Conclusions: HSP70 and HSF1 overexpression and correlation with poor prognosis in CLL patients underline their pivotal role in the regulation of leukemic B cell survival. HSP70 and HSF1 both correlation and reduction in CLL patients following *in vivo* Ibrutinib regimen let us hypothesize a role of these proteins in the progression of the disease. In normal B cells HSP70 and HSF1 are both localized into the nucleus after stress conditions, however we found both HSP70 and HSF1 localized into the nucleus of CLL B cells at steady state, suggesting a constitutive activation of these proteins in CLL. Although HSP70 has been extensively linked to cancer, little progresses have been made in bringing HSP70 inhibitors to the clinic, because of their potential off-target effects. For this reason we tried an alternative approach by targeting the HSP70 major regulator, HSF1. We observed that both inhibitors, Zafirlukast and Fisetin, lead to an *in vitro* dose dependent B cell apoptosis. These data demonstrate HSP70 and HSF1 involvement in the pathogenesis of CLL and identify HSP70/HSF1 axis as a target for new therapeutic strategies.

PB1771

OVEREXPRESSION OF GENE FOR HUMAN CONCENTRATIVE NUCLEOSIDE TRANSPORTER 3 IS A PREDICTOR OF RESISTANCE TO FLUDARABIN-BASED CHEMOTHERAPY IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

V. Vukovic[1,*], D. Antic[1,2], T. Karan-Djurasevic[3], N. Milic[4], M. Todorovic-Balint[1,2], J. Bila[1,2], B. Andjelic[1,2], V. Djurasinovic[1,2], A. Sretenovic[1], M. Smiljanic[1], J. Jelicic[1], M. Dencic-Fekete[1], M. Perunicic-Jovanovic[1], N. Kraguljac-Kurtovic[1], S. Pavlovic[3], B. Mihaljevic[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Medical Faculty, University of Belgrade, [3]Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, [4]Institute for Medical Statistics and Informatics, Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: Human concentrative nucleoside transporter 3 (hCNT3) belongs to a family of nucleoside transporters involved in fludarabine cellular uptake. It has been reportedthat overexpression of *SLC28A3* gene encoding hCNT3 predictspoor response to fludarabin-based chemotherapy.However, the mechanisms by which elevated expression of *SLC28A3* mediate fludarabine resistance are still elusive.
Aims: The aim of the study was to examine possible influence of *SLC28A3* gene overexpression on treatment response to fludarabine-cyclophosphamide therapy (FC) in patients with chronic lymohocytic leukemia.
Methods: We retrospectively analysed data from 54 CLL patients diagnosed and treated at Clinic for Hematology, Clinical Center of Serbia from 2003 to 2013. Blood samples were prospectively collected and analysed for biological and molecular features, as well as standard laboratory parameters. The expression of *SLC28A3* gene was analyzed in peripheral blood mononuclear cells by RQ-PCR methodology, using TaqMan chemistry and Abl as endogenous control gene. Quantification of target gene expression was made by comparative ddCt method, using HL-60 cell line as the calibrator. All analyses were done prior to any treatment.
Results: Median age at diagnosis was 57 years (range 38-75). All patients were treated with fludarabin-based chemotherapy, 45 (83%) in the first treatment line. Overall response rate to the first line therapy was 81%, equally distributed on complete and partial responses (CR and PR), while the remainder included the same number of patients with stable disease (SD) and progressive disease (PD) (5, 9.6%). Most of the patients (42, 78%) relapsed during the follow up. At the time of the last follow up 14 (26%) patients were still alive, 35 (65%) were dead, and 5 (9%) were lost to follow up. Median overal survival was 76 months.
In the group of patients who received FC in the first treatment line (43/54), median expression of *SLC28A3* mRNA in patients who experienced CR, PR, SD and PD was 0.036±0.030, 0.062±0.063, 0.030±0.025 and 0.157±0.257, respectively. The level of *SLC28A3* expression was not associated with the *IGHV* mutational status. Patients who experienced PD to FC treatment overexpressed gene for hCNT3 compared to patients who achieved CR (p=0.013) and PR (p=0.05). We detected a significantly higher level of *SLC28A3* expression in patients who experienced PD to FC treatment in comparison to patients who achieved CR (p=0.013) and PR (p=0.05).
Summary/Conclusions: Overexpression of *SLC28A3* gene is a predictor of resistance to treatment with FC chemotherapy. Further studies are warranted to confirm these findings.

PB1772

THE SPECTRUM OF TP53, SF3B1, AND NOTCH1 MUTATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS EXPOSED TO IONIZING RADIATION DUE TO THE CHORNOBYL NPP ACCIDENT

N. Bilous[1,*], I. Abramenko[1], A. Chumak[1], I. Dyagil[2], Z. Martina[2]
[1]Clinical Immunology, [2]Hematology, Research Center for Radiation Medicine, Kiev, Ukraine

Background: Generally, chronic lymphocytic leukemia (CLL) is considered to be a non-radiogenic form of leukemia. We previously found some clinical and biological features of CLL in group of clean-up workers of Chornobyl NPP accident indicated unfavorable disease course, such as high frequency of solid tumors and Richter transformation, mainly unmutated status of heavy chain variable region (*IGHV*) genes with increased usage of *IGHV1-69* and *IGHV3-21* (Abramenko *et al.*, 2008). Analysis of genetic features of leukemic cells in IR-exposed CLL patients may provide an additional data on the possible causal relationship with IR.
Aims: the aim of the study was to analyze *TP53*, *NOTCH1 and SF3B1* mutations in CLL patients, sufferers of Chornobyl NPP accident to clarify the possible pathogenetic relationship between IR and CLL development
Methods: *TP53*, *NOTCH1*, and *SF3B1* mutations were analyzed in 106 CLL patients who have been exposed to ionizing radiation (IR) due to Chornobyl NPP accident (83 clean-up workers, 16 inhabitants of radionuclide contaminated areas, and 7 evacuees) and in 130 IR non-exposed CLL patients as the control group. *TP53* gene mutation analysis was performed for exons 3 to 10. *NOTCH1* mutations and *SF3B1* mutations were analyzed in the hotspot regions of these genes were the vast majority of CLL-specific lesions were reported: in c.7282_ 7680 region in exon 34 of *NOTCH1* gene, and in exons 14, 15 and 16 of *SF3B1* gene, correspondingly.
Results: We found *TP53* and *SF3B1* mutations with similar incidence in both groups – in 11.3% and 10.0% of IR-exposed patients, and in 12.7% and 11.5% of IR non-exposed CLL patients, respectively. In contrast, *NOTCH1* mutations were found with significantly lower frequency in IR-exposed patients in comparison with the control group (6.7% *vs* 17.7%; p=0.012). Some other features were found among IR-exposed CLL patients also. Specifically, *TP53* mutations were seen with equal frequency among mutated (11.1%) and unmutated (11.8%) *IGHV* cases in IR-exposed CLL patients, while the tendency to prevalence of *TP53* mutations in unmutated compared with mutated *IGHV* cases was found in the control group (14.1% and 5.6%, correspondingly; *p*=0.178). In IR-exposed group *SF3B1* mutations were combined with mutations in *TP53* almost in half of detected cases. In opposite, in the control group we observed reported earlier mutual exclusivity between *SF3B1* and *TP53* lesions (p=0.001 in comparison between observed groups). Among IR-exposed CLL patients we found two different cases with identical rare mutation of *TP53* gene - c.665C>T substitution leading to change proline for leucine at codon 222 (Pro222Leu). This substitution is very likely to represent inherited *TP53* mutation, which may influence CLL development under IR exposure.
Summary/Conclusions: In summary, our data suggest that *TP53* abnormalities are involved in CLL development in sufferers of the Chornobyl NPP accident and also a possible interaction between inherited IR sensitivity caused by mutation in *TP53,* radiation and CLL development.

PB1773

DRUG SENSITIVITY SCREENING IN CHRONIC LYMPHATIC LEUKEMIA AND MULTIPLE MYELOMA FOR PERSONALIZED CANCER THERAPY

D.B. Thimiri Govinda Raj[1,*], S.S. Skanland[1], D. Wang[2], G.E. Tjønnfjord[3], L.A. Munthe[2], K. Tasken[1]
[1]1Centre for Molecular Medicine Norway (NCMM), Nordic EMBL Partnership, University of Oslo and Oslo University Hospital, NCMM UIO, [2]Centre for Immune Regulation, Institute of Clinical Medicine, University of Oslo, [3]Department for Haematology, Oslo University Hospital, Oslo, Norway

Background: Personalized Cancer Medicine is rapidly developing field that includes predictive medicine, preventive medicine and various personalized or individualized therapies, *e.g.* labeled "precision medicine". One particular challenge with cancer is that origin of each cancer is a clonal event evolving into tumor heterogeneity. We focus on Chronic Lymphocytic Leukemia (CLL), Multiple Myeloma and Follicular lymphoma (FL) that are currently considered incurable. Although current treatment regimens prolong life for patients, CLL and MM cancer eventually relapse. Current challenges in using therapeutics against CLL and MM includes design of optimal treatment for individual patients based on characterization the tumor and its intratumor heterogeneity as observed by whole genome sequencing. Efficient therapies require a personalized approach that combines targeting lymphoma cells and the tumor microenvironment by restoring the patient's own anti-tumor immunity. One solution to this challenge is the so-called "n-of-one" studies where protocols are organized with diagnostically based patient stratification to individualized treatments (n=1).
Aims: To introduce individualized treatment for patients against available therapies, we aim to established cell-based assays and drug sensitivity platform at NCMM, University of Oslo and Oslo University Hospital. To establish a pipeline for direct drug senstivity screening in CLL and MM (WP1-Path A). To Complement the results from WP1-Path A, with Signaling pathway analysis (WP2-Path B) towards testing in xenografted mice and implementing therapy in n-of-one clinical trials. To Offer patients with intractable CLL and MM individualized treatment with an effective combination of targeted therapies.
Methods: We culture CLL cells with combination of feeder cells that express CD40L, APRIL and BAFF for 24 hours stimulation. We perform drug sensitivity screening with Prestimulated CLL cells in 384 well formats without feeder cells. We culture MM cells in 384 well format for drug screening in response to T_{helper} cells prestimulation in the presence of IL2. To support high-throughput drug sensitivity screening , We use cell-based assays such as CellTiter-Glo® Luminescent Cell Viability Assay and CellTox™ Green Cytotoxicity Assay to define drugs that inhibit cancer cell growth. Additional methods such as cell proliferation assay, CellTox Green, apoptosis and oxidative stress (glutathione release) are also applied. We also use established cell barcoding on CLL/MM for flow cytometry (7-AAD/BrdU cell proliferation and Caspase8/9 apoptosis assay).
Results: Standard Curve for cell proliferation, CellTiter-Glo assay has been performed for MM/CLL cells. Time course measurement using cell proliferation, CellTox-Green assay for CLL cells (unstimulated and soluble CD40 ligand stimulated) has been performed. Time course measurement (0,24,48,72 hrs and 5 days) using cell proliferation, CellTox-Green assay for M2 cells has been performed. Benzalkonium chloride (BzCl) is used as Positive control. Endpoint measurement using CellTiter-Glo assay for CLL and MM cells was performed with cell density of 5000. Dose Response curve for 50 drugs has been generated for CLL patients (n=4) and MM (n=4) (Figure 1).

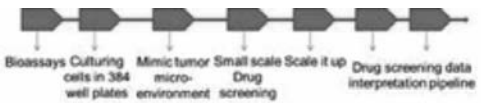

Figure 1.

Summary/Conclusions: We perform drug sensitivity screening to select potential drug candidates and pathway inhibitors through an approach where we directly assess patient samples. Selected drug candidates will first be validated by bioassays and flow cytometry to assess effects on intracellular mitogenic pathways (phosphoflow-based approach). We propose to use the drug sensitivity screening platform to identify and validate drug candidates for xenografting and "n-of-one" clinical trial studies.

PB1774

FCGR2A AND FCGR3A VARIANTS ARE NOT ASSOCIATED WITH RESPONSE TO RITUXIMAB IN PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

M. Pavkovic[1,*], S. Trpkovska-Terzieva[1], R. Angelovic[1], O. Karanfilski[1], T. Sotirova[1], L. Cevreska[1], A. Stojanovic[1]
[1]University Clinic for Hematology, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Chronic lymphocytic leukemia (CLL) is the most common form of adult leukemia in Western world with highly variable clinical outcome. Rituximab is a monoclonal chimeric anti-CD20 agent, that has demonstrated significant benefit for patients with different form of B cell lymphoproliferative disorders. Chemoimmunotherapy with rituximab, fludarabine and cyclophosphamide (R-FC) has shown to prolong progression free survival (PFS) and overall survival in CLL patients compared with chemotherapy alone. FCGR2A is polymorphic and has two alleles, FCGR2A-131H and FCGR2A-131R. This polymorphic variation is due to a single base substitution of nucleotide adenine for guanine in position 494. FCGR2A-H131 allele has a higher affinity for human IgG2, comparing to FCGR2A-R131. The gene for FCGR3A has also two polymorphic variant alleles: 158 valine (V158) and phenylalanine (F158) due to single base substitution of timidine to guanine at nucleotide position 559. FCGR3A-158V variant has higher affinity for Fc gamma receptor than 158F variant. These Fc gamma receptor polymorphisms may influence antibody-dependent cytotoxicity (ADCC), complement-dependent cytotoxicity (CDC) and direct proapoptotic effect.
Aims: The aim of our study was to investigate a possible association of these two FCGR2A and FCGR3A variants with response to R-FC therapy in CLL patients.
Methods: We have analyzed these two polymorphisms in 90 patients with CLL treated with R-FC regimen. Median age of our patients was 62.7(36-78) and 63% were male. Number of patients with stage III/IV disease was 65(72%) and median WBC count at the start of treatment was 68.5(34-173x10^9/L). Percentage of previously treated patients was 51/90 (56.6%). Average numbers of R-FC cycles were 4.3 and median PFS was 35.1 months. Median time of observation after treatment was 3.6 years (range:6 months-8 years). Response was evaluated 2 months after therapy according to National Cancer Institute (NCI) criteria. Complete response (CR) was achieved in 24/90 (26.7%), partial response (PR) in 56/90 (62.2%) and no response in 10/90 (11.1%). DNA was isolated from peripheral blood mononuclear cells and genotyping was performed by using PCR/RFLP methods. The distribution of genotypes was compared by using a chi-squared test or Fisher's exact test.
Results: Distribution of genotypes in our patients was: 33% H/H, 49% H/R and 18% R/R for FCGR2A and 43% V/V, 40% V/F and 17% F/F for FCGR3A. Rate of CR and PR were similar irrespective of the FCGR variants and our results did not demonstrate significantly different genotype distribution for FCGR2A (p=0.8001) or FCGR3A (p=0.1019) in CLL patients with complete, partial or no response to R-FC treatment (Table 1).

Table 1. Genotype distributions for FCGR2A & FCGR3A in patients with CLL.

FCGR2A/FCGR3A	Complete Response n=24(26.7%)	Partial Response n=56(62.2%)	No Response n=10(11.1%)	p-values
FCGR2A 131H/R				
(131H/H)	8(26.6%)	18(60%)	4(13.4%)	0.8001
(131H/R)	10(22.7%)	29(65.9%)	5(11.4%)	
(131R/R)	6(37.5%)	9(56.3%)	1(6.2%)	
FCGR3A 158F/V				
(158 F/F)	8(20.5%)	29(74.4%)	2(5.1%)	0.1019
(158 F/V)	11(30.6%)	21(58.3%)	4(11.1%)	
(158 V/V)	5(33.3%)	6(40%)	4(26.7%)	

Summary/Conclusions: Our results are similar with previously reported results in other studies in CLL patients, but in contrast with the results for follicular lymphoma (FL), which showed that high-affinity FCGRA-158V/V variant was associated with the highest response rates in FL patients treated with rituximab. These findings could be explained with the different mechanism of action of rituximab in CLL compared to lymphoma patients or could be due to the variations in selected patient's population.

PB1775

MUTATIONAL STATUS, IMMUNOGLOBULIN HEAVY VARIABLE GENES PATTERN AND STEREOTYPED RECEPTORS REPERTOIRE OF MACEDONIAN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

I. Panovska-Stavridis[1,*], S. Trajkova[1], M. Ivanovski[1], M. Popova-Labacevska[1], A. Pivkova-Veljanovska[1], D. Dukovski[1], A. Eftmov[2], M. Staninova-Stojovska[2], N. Matevska-Geshovska[2], L. Cevreska[1], A.J. Dimovski[2]
[1]University Clinic of Hematology-Skopje, [2]Center for Biomolecular Pharmaceutical Analyses, Faculty of Pharmacy, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: The mutational status of the immunoglobulin heavy variable (IGHV) genes is established as one of the most important prognostic molecular genetic markers in chronic lymphocytic leukemia (CLL). It divides the CLL patients into two subsets with a different clinical course, mutated (M-CLL) and unmutated (U-CLL). U-CLL is delineated with a cutoff value of 98% identity with the closest germ line of IGHV genes. The shaping of the CLL IGVH gene repertoire depends on a different genetic background and effects of the environmental factors. In addition, a strong bias in the use of individual genes and subgroups between normal and malignant B-cells and presence of highly homologous "stereotyped" heavy complementary-determining region 3 (VH-CD3) is shown, which suggests the role of a specific antigen in the pathogenesis of the disease.
Aims: In this study, we analyzed the mutation status and pattern of IGHV, IGHD and IGHJ gene usage in Macedonian CLL patients.
Methods: Ninety-seven consecutive CLL patients that presented at the University Clinic of Hematology –Skopje in the period between 2011-2013, were included in the study. IGHV mutation status and gene repertoire were analyzed using the reverse transcriptase– polymerase chain reaction (RT-PCR) and sequencing methodology. The mutational status of the IGVH genes was determined using two databases: IMGT/V-QUEST tool and IgBLAST software. The stereotyped subset assignment was performed using ARResT/AssignSubset tool (Bioinformatics Analysis Team).
Results: We found that 44.3% of the cases belonged to M-CLL and 55.7% to U-CLL, with a progressive disease dominant in the U-CLL subset. Both groups were comparable regarding the age and gender distribution. Only 39% of the M-CLL patients presented with a progressive disease, compared to 74% of the U-CLL patients (p<0.05).The comparison of median time to the first treatment (TTT) between M-CLL and U-CLL (39 months *versus* 8 months, respectively) showed a statistically significant difference between the groups (p<0.01). Most frequently expressed IGVH genes were: the IGHV3 subgroup (44.3%), followed by IGHV1 (28.9%), IGHV4 (23.7%), IGHV5 (2.0%), and IGHV2 (1.0%). Among 32 different IGVH genes, 8 genes were found (V1-46,V1-69,V3-21,V3-23,V3-30,V3-33,V3-48 & V4-34) in 58.8% of all cases, revealing a strong bias in IGVH gene expression in CLL. IGHV1-69 was the most frequently expressed gene of all genes (16.5%), and exclusively found in the U-CLL group demonstrating a frequency of 29.6%. The IGHV3-21 was detected with a low frequency of 4.1%, as reported for CLL patients from other Mediterranean countries. The distribution of IGHD subgroups was as follows: IGHD3, 52.6%; IGHD2, 17.5%; IGHD6, 13.4%; IGHD1 7.2%; IGHD4 7.2%; and IGHD5 2.09%. The most frequent IGHJ gene was IGHJ4 (49.4%), followed by IGHJ6 (239.2%), IGHJ5 (13.4%), IGHJ3 (11.4%) and IGHJ2 (3.8%), IGHJ1 (2.09%). In 10.1% of the cases, the VHCDR3 amino acid sequences belong to previously defined stereotyped clusters. Only one of the rearrangements with stereotyped VH-CD3 belonged to the M-CLL subset.
Summary/Conclusions: Our study showed a strong correlation between IGHV gene mutational status and clinical course of CLL. Results on IGHV-IGHD-IGHJ genes usage in our study are comparable to the previously reported from Mediterranean countries. The high frequency of V1-69gene and low frequency of IGVH3-21 in our CLL patients that originate from a small geographic region further promotes the geographic bias in the use of IGVH genes and points to an important role in antigen stimulation in the pathogenesis of the CLL subsets. Our findings indicated a lower expression of the stereotyped BCR region than those previously reported (~30%), but they were comparable with the results reported for the Serbian CLL patients (10.1% *versus* 15,3%, respectively), in the only previous published study of this kind from Western Balkans.

Chronic lymphocytic leukemia and related disorders - Clinical

LAMBDA LIGHT CHAIN RESTRICTION – USEFUL FOR HAIRY CELL LEUKEMIA PROGNOSTICATION?

J. Araújo[1,*], M. Sobrinho-Simões[1], S. Afonso[1], F. Príncipe[1], J.E. Guimarães[1]
[1]Hematology, Centro Hospitalar de São João, Porto, Portugal

Background: Hairy cell leukemia (HCL) patients have near-normal life expectancies since the introduction of purine nucleoside analogues. However, HCL remains a chronic, often relapsing disease in which maximizing treatment-free survival (TFS) is the main goal.
Aims: Prognostication is not standardized in HCL, emphasizing the relevance of the characterization of HCL populations.
Methods: We retrospectively analysed 40 patients (90% men), diagnosed between 1997 and 2016, with a median follow-up of 6 years.
Results: At presentation, the median age was 58 years and 69% of patients were symptomatic - fatigue (53%), B symptoms (50%), bleeding (14%), abdominal discomfort (6%) and severe infection (22%). The commonest cytopenia was thrombocytopenia (70%), with median platelet count being 66x10^9/L. Monocyte counts below 0.1x10^9/L were observed in 61% of the patients. Splenomegaly was observed in 83% of the patients and 21% had abdominal lymphadenopathies. The majority of the patients (88%) was treated with cladribine in first line, achieving an overall response (OR) rate of 100% and a complete response (CR) rate of 38%, of which 67% were classified as minimal residual disease (MRD)-negative CR. Retreatment was required in 33% of the patients, of which the majority received cladribine. The median time-to-next-treatment (TNT) from first to second line was 3 years. The OR rate for second-line treatment was 91%, 50% achieving CR, of which 33% were classified as MRD-negative CR. Only 5% of the patients required further treatment lines. Even the presence of scarce hairy cells in the bone marrow precluded classification of response as CR. This might have contributed to the low CR levels observed in our patients. As post-treatment bone marrow biopsies were available in only 24 patients, response analysis was restricted to these patients. All of these 24 patients had bone marrow fibrosis at diagnosis, which reverted when and in whom first CR was obtained. Median overall survival (OS) was not reached and, at 10 years, the OS was 90%. Four deaths occurred, all unrelated to HCL. Regarding prognostication, a trend to a longer TFS, albeit no statistically significant, was observed in patients achieving CR (namely MRD negative) and without thrombocytopenia at presentation. Excitingly, the 61% of patients with kappa (k) light-chain restriction (LCR) displayed a significantly higher TFS than the 39% with lambda (λ) LCR (p 0.034, Wilcoxon-Gehan test). To the best of our knowledge, there are no published reports on prognostic value of LCR in HCL (Figure 1).

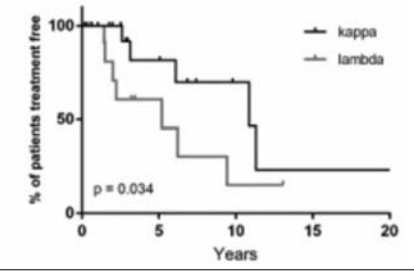

Figure 1.

Summary/Conclusions: If multicentre studies corroborate our findings, LCR may be of use in the prognostication/risk stratification of HCL. Similarly with multiple myeloma and other hematological malignancies, lambda (λ) LCR appears to correlate with worse prognosis, leading to a shorter TFS.

PB1777

CLINICAL EFFICACY AND LONG-TERM OUTCOMES OF SPLENECTOMY IN CHRONIC LYMPHOCYTIC LEUKEMIA

Y. Yevstakhevych[1,*], I. Yevstakhevych[1], O. Vygovska[1], M. Semerak[1], V. Loginskiy[1]
[1]SI "Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine" , L'viv, Ukraine

Background: Chronic lymphocytic leukemia (CLL) is often accompanied by splenomegaly. In certain cases the spleen may enlarge to a giant size, causing abdominal discomfort, regional portal hypertension, and becomes a place of malignant cells concentration. In 2.3-4.3% of cases CLL may be complicated by autoimmune cytopenias (autoimmune hemolytic anemia (AIHA), immune thrombocytopenia (ITP), Evans-Fisher syndrome). Accordingly, the effectiveness of steroid and chemotherapy in such cases may be impaired, raising the question of splenectomy advisability.
Aims: To analyze splenectomy effectiveness in patients with CLL.
Methods: Splenectomy was performed in 41 patients with CLL, 12 of which were patients with CLL and ITP, 9 with CLL and warm type AIHA, 5 patients with CLL and Evans-Fisher syndrome, along with 15 CLL patients without immune disorders. Among the patients there were 26 males and 15 females. Indications to splenectomy were following: massive splenomegaly with abdominal discomfort, immune cytopenia and regional portal hypertension. In one female patient the surgical intervention was performed urgently due to spontaneous splenic rupture and acute intra-abdominal bleeding.
Results: Splenectomy was effective in 37 patients (90.2%): abdominal discomfort disappeared, hemolysis stopped and hemoglobin levels normalized or increased, platelets numbers normalized or increased. Splenectomy was ineffective in 3 patients with CLL associated with ITP: amid elimination of abdominal discomfort the platelets number did not increase significantly (2 patients), while in 1 patient despite increase in platelets number leukemia progression was observed. One (2.4%) patient with CLL and AIHA died on 3rd day after surgery because of acute adrenal insufficiency. The analysis of late effects of splenectomy in patients with CLL showed that average life expectancy after the surgery comprised 111.6 months within observation period between 11 and 277 months. In patients with CLL with immune cytopenias the average life expectancy after surgery was shorter and equal to 60.7 months within the observation period between 2 and 361 months.
Summary/Conclusions: Splenectomy remains an effective method of treatment of patients with CLL accompanied by severe splenomegaly and immune cytopenia. Long-term results of splenectomy in patients with CLL without cytopenia are better than in patients with CLL and cytopenias. Aggressive hemolysis, large spleen covered in perisplenic adhesions, amid portal hypertension and thrombocytopenia are considered to be special surgical risk factors in this patients.

PB1778

MONOCLONAL B-CELL LYMPHOCYTOSIS IN THAI POPULATION: PREVALENCE AND IMMONOPHENOTYPIC CHARACTERISTICS

P. Kongtim[1,*], J. Chantakarm[1], W. Limvorapitak[1], N. Wanisorn[2], T. Sinthuwiwat[3], W. Udomchaiprasertkul[3], S. Issaragrisil[4]
[1]Hematology, [2]Pathology, Faculty of Medicine Thammasat University, Pathumthani, [3]Cancer Cytogenetic and Molecular Diagnostic, Chulabhorn Research Institute , [4]Hematology, Faculty of Medicine Siriraj Hospital Mahidol University , Bangkok, Thailand

Background: Monoclonal B-cell lymphocytosis (MBL) is characterized by the presence of <5X10^9 clonal B-cells/L in peripheral blood (PB) in otherwise healthy subjects, in the absence of symptoms and signs of a B-cell lymphoproliferative disorder (LPD). MBL is considered a precursor to chronic lymphocytic leukemia (CLL) and other B-cell malignancies.
Aims: To study the immunophenotypic features and prevalence of MBL in healthy Thai individuals.
Methods: Peripheral blood (PB) samples from 616 healthy Thai individuals (313 female), 18-80 year-old with normal lymphocyte counts were immunophenotyped using high-sensitive flow cytometry, based on 5-color staining and the screening for >5 × 10^6 total PB leukocytes. The initial PB samples were screened for clonal B cells using MultiMix Triple-Color Reagent (Kappa Light Chains/FITC, Lamba Light Chains/RPE and CD19/RPE-Cy5). In those cases in which a clonal B cell population was detected by imbalanced of sIgK:sIgL ratio of >3:1 or <1:3, were further tested for CD5, CD23, CD20 and CD79a expression.
Results: Of total 616 subjects, MBL was found in 8 cases (1.2%) including 3 and 5 female and male cases respectively. Among 40 years or older, MBL was found in 5 out of 448 cases (1.1%). Compared with non-MBL group, subjects in MBL group were significantly older (median age of 78 years *versus* 50 years; p=0.01) and had a significant higher number of absolute and B-lymphocyte count (median 3.1 *versus* 1.6 X 10^9/L; p=0.03 and 0.35 *versus* 0.16 X10^9/L; p=0.02, respectively) while the median white blood cell count was not different between 2 groups. Also, there were more subjects in MBL group who had family history of lymphoproliferative diseases (LPD; 37% *vs* 0%; p<0.01) and influenza vaccination within 2 years (50% *vs* 8.7%; p=0.003). Among 8 cases with MBL clone, 6 cases had low-count MBL (<0.5X10^9 clonal B-cells/L) while only 2 cases had high-count MBL (>0.5X10^9 clonal B-cells/L). All 8 cases had persistent positivity of MBL clone after tested was repeated within 3 months after the initial test. In the follow up test, only 1 case with initial high-count MBL had decrease number of B cell clone and became low count MBL. There was not significant different in age between subjects in low and high-count MBL group. Six cases had typical CLL phenotype MBL clone (CD5+, CD23+, CD20+/dim and light chain restriction). Whereas 1 case had atypical CLL phenotype MBL (CD5+, CD20+ and light chain restriction but CD23-) and 1 case had non-CLL phenotype MBL (CD20+ but CD5-). In univariate analysis, age (RR 4.19; 95%CI 1.0-17.7; p=0.049), absolute lymphocyte count (RR 2.76; 95%CI 1.01-4.87; p=0.047), family history of LPD (RR 122; 95%CI 51.1-293.4; p<0.001) and

influenza vaccination (RR 10.47; 95%CI 2.54-43.07; p=0.003) were associated with increase risk of developing MBL. After adjusted for age, only history of influenza vaccination and family history of LPD were an independent risk factor for developing MBL with age adjusted RR of 9.75 (95%CI 2.3-40.5; p=0.002) and 92 (95%CI 56.3-149.5; p<0.001), respectively.
Summary/Conclusions: MBL prevalence in Thai population is much lower than previously reported. It more frequent in elderlies and associated with family history of LPD and influenza vaccination. Although uncommon, the presence of high-count MBL warrants further investigations to define the biological and clinical significance in term of LPD transformation and long-term survival.

PB1779

SPONTANEOUS CLINICAL REGRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA: CLINICAL AND BIOLOGIC FEATURES OF 9 CASES FROM THE ERIC REGISTRY

I. Del Giudice[1,*], A. Visentin[2], L. Trentin[2], M. Flogegard[3], C. Cavallloni[4], E.M. Orlandi[4], M. Mattsson[5], S. Raponi[1], C. Ilari[1], L. Cafforio[1], M.S. De Propris[1], I. Della Starza[1], N. Peragine[1], P. Mariglia[1], G. Semenzato[2], A. Guarini[6], E. Montserrat[7], R. Foà[1]
[1]Department of Cellular Biotechnologies and Hematology, Hematology, Sapienza University, Rome, [2]Department of Medicine, Hematology and Clinical Immunology Unit, University of Padua, Padua, Italy, [3]Hematology, Medicine Clinic, Falun Hospital, Falun, Sweden, [4]IRCCS, Policlinico San Matteo, Pavia, Italy, [5]Department of Hematology, Uppsala University Hospital, Uppsala, Sweden, [6]Department of Molecular Medicine, Hematology, Sapienza University, Rome, Italy, [7]Department of Hematology, Hospital Clinic, University of Barcelona, Barcelona, Spain

Background: Spontaneous clinical regression in chronic lymphocytic leukemia (CLL) is rare (1% per year). We previously reported on the clinico-biologic features of 9 Binet stage A CLL patients from our Center in Rome who experienced a persistent spontaneous clinical regression of the disease at a median time of 11 years from diagnosis, maintained after 5 more years of follow-up. The lymphocyte count at CLL regression was 3.16 x 10^9/L (1.3-4.9), with a persistent small CLL clone (CD19+/CD5+/CD23/light chain restricted: 44%, range 5-60%). Biologic features included negative CD38, mutated IGHV, often with VH3-30 and Vk4-1 usage, and a distinctive gene expression profile.
Aims: To conduct a retrospective collection of clinical data and basic biologic information on CLL spontaneous regressions and to make them accessible for future research.
Methods: A registry of spontaneous CLL regressions (absence of lymphadenopathy, splenomegaly or constitutional symptoms, peripheral blood (PB) lymphocytes <4 x 10^9/L, in the absence of any previous treatment) was launched within the ERIC consortium.
Results: So far, 9 CLL patients showing a spontaneous regression have been reported and 8 have been formally registered, 7 from Italy and 2 from Sweden. Six were males and 3 females, with a median age of 57 years at diagnosis (range 51-82), stage Binet/Rai A/0 in 6, A/I in 2 and B/II in 1. The median lymphocyte count at diagnosis was 14.1 x 10^9/L (5.3-51.9). Biologic features included: mutated IGHV in 8/8 with VH3-30 (2), VH3-21, VH3-15, VH3-23, VH4-31, VH4-34, VH4-59; CD38 <30% in 6/6; ZAP70 <20% in 4/6; FISH (7 cases): del13q in 4, negative in 3, +12 in 1 case. No patient had undergone treatment, except for one diagnosed in 2009 who received FCR for disease progression in 2013 (lymphocytes 107 x 10^9/L), obtained a PR and 18 months later developed a Richter's syndrome - a diffuse large B-cell lymphoma clonally unrelated to CLL - with the concomitant disappearance of the CLL clone from the PB and bone marrow, that has lasted up to January 2017 (lymphocytes 3.5 x 10^9/L, CLL 0.035 x 10^9/L). An additional case diagnosed in 2013 (stage A/I, lymphocytes 37.2 x 10^9/L) reached the highest lymphocyte count 19 months later (91.2 x 10^9/L) and subsequently started a spontaneous reduction in lymphocytosis down to 39.6 x 10^9/L in 2015 and to 8.9 x 10^9/L in January 2017 in stage A/0, indicative of a partial but ongoing CLL regression. Excluding the latter cases, in the other 7, all in stage A/0, the highest lymphocyte count was 16.0 x 10^9/L (8.9-76.0), the lowest at the last follow-up was 2.8 x 10^9/L (1.8-4.4), with 0.66 x 10^9/L CLL cells (0.085-3.0) in the 4 evaluable cases. The median time from diagnosis to clinical regression was 4 years (range 2-17) and this has been maintained for 2 further years (range 0.5-7). One of these cases (mutated VH3-21, +12) seems the most dramatic: in 2008 at diagnosis, the lymphocytes were 51.9 x 10^9/L, in 2009 a peak at 76.0 x 10^9/L was recorded; in 2011, when the CLL regression started, the patient underwent several mild viral upper respiratory infections; the CLL complete regression (1.8 x 10^9/L) persists up to the last follow-up. In 5/9 cases one event - mild viral infections, a cerebral hemorrhage, a stroke, a pelvis fracture and a Richter's syndrome - occurred before the spontaneous regression, but no relevant drug intake was recorded.
Summary/Conclusions: Clinicians should be aware that spontaneous regression is a possibility, albeit infrequent, in the natural history of CLL. The collection and study of such cases within the ERIC registry may shed light on mechanisms leading to spontaneous regression and critical pathways in immunosurveillance in CLL.

PB1780

CLINICAL AND LABORATORY CHARACTERIZATION OF PLATELET DYSFUNCTION DURING IBRUTINIB TREATMENT IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA. MONOCENTRIC EXPERIENCE

I. Innocenti[1,*], M.A. Alberelli[2], F. Autore[1], S. Sica[1], E. De Candia[2], L. Laurenti[1]
[1]Department of Hematology, Catholic University of Sacred Heart, Rome/ Institute of Hematology, [2]Department of Oncology and Hematology, Catholic University of Sacred Heart, Rome/ Institute of Internal Medicine, Rome, Italy

Background: Ibrutinib (IBR) is a potent and irreversible inhibitor of Bruton's tyrosine kinase (Btk) approved by FDA for the treatment of patients (pts) affected by chronic lymphocytic leukemia (CLL) with del 17p or *TP53* mutation or for pts with relapsed/refractory (R/R) CLL. IBR is associated with bleeding events usually mild (Common Toxicity Criteria (CTC) grades 1-2), rarely severe (grade 3-4). A defect of platelet function, namely an inhibition of Btk-mediated signaling by platelet glycoproteins (GP) GPVI and GPIb, has been hypothesized to cause these bleedings. IBR associated bleedings and platelet dysfunction may be relevant in CLL pts who are usually elderly and with comorbidities requiring antithombotic therapies.
Aims: To investigate and characterize the effect of IBR on platelet function in pts with CLL.
Methods: We enrolled from May 2014 to December 2016 twenty pts with CLL treated with orally administered 420 mg daily of IBR; 18 R/R CLL pts received IBR in monotherapy and 2 pts with previously untreated CLL received IBR in association with anti-CD20 MoAb. Median age was 68 years (57-84); 13 pts had unmutated IgVH and 2 had 17p deletion. The median number of prior therapies in R/R CLL pts was 3 (2-7). Five pts discontinued IBR therapy: 2 for Richter's transformation, 1 for progressive CLL, 1 underwent allogeneic HSCT, 1 for heart disease. The platelet function was studied before and during IBR by light transmission aggregometry (LTA) using platelet-rich plasma and the following agonists: ADP 2-4 uM, PAR1-AP 25 uM, Collagen 10-3.3-2 ug /mL, arachidonic acid 1 mM, ristocetin 0.6-1.2 mg/mL. Also measurements of von Willebrand factor antigen (vWF:Ag) and ristocetin cofactor activities (RiCo) by chemiluminescent immunoassay were performed. All pts had measurements of the platelet function at the baseline and after 1, 3, 6 months initiation of IBR and then every 3 months up to 24 months. Median observation period was 9 months. No patient received concomitant antiplatelet or anticoagulation therapy.
Results: Nineteen pts achieved a partial response and an increase of hemoglobin and platelet count. We recorded CTC grade 1 or 2 bleedings (bruising, petechiae, conjunctival and retinal hemorrhage, rectal bleeding) in 15 pts; no patient needed IBR interruption or dose reduction. All pts displayed severe impairment of collagen induced aggregation upon IBR. Reduction of maximal aggregation (35.6+/- 32% *vs* 70.6+/- 21% baseline) and prolongation of the lag phase (261+/- 54 sec *vs* 72+/- 26.8 sec baseline) by 2 ug/mL collagen was measured in all pts during IBR. In 10 pts a significant improvement of the aggregation by 2 uM ADP (71+/- 31.8% *vs* basal 48.6+/- 31%) and 4 uM ADP (84+/- 11% *vs* basal 64+/- 25%) was found during IBR. The aggregation by 25 uM PAR1-AP, 1.2 mg/ml ristocetin and 1 mM arachidonic acid was unchanged before and under IBR. Finally, in 9 pts the vWF:Ag and RiCo were high at the onset of the disease (163+/- 59.8% and 181.6+/- 82.5%) and reduced up to normal values under IBR (118+/- 71% and 145+/- 65%).
Summary/Conclusions: Our study showed minor bleedings in pts treated with IBR. A severe impairment of collagen-induced aggregation was caused by IBR, which was counteracted by amelioration of ADP-induced aggregation, that could explain, at least partially, the mild clinical phenotype in treated pts. The assessment of platelet function in IBR treated CLL pts could help to predict and monitor the bleeding risk, and to guide pts through invasive procedures. In addition, pts under anticoagulant or antiplatelet treatment might need be carefully monitored by clinical and laboratory evaluation.

HAIRY CELL LEUKEMIA :A SUMMARY OF CLINICAL DATA ON 202 PATIENTS AND THE RESULTS OF THERAPY WITH CLADRIBINE IN ISRAEL

M. Inbar[1], Y. Herishanu[2], N. Goldschmidt[3], O. Bairey[4], M. Yuklea[5], L. Shvidel[6], R. Fineman[7], A. Aviv[8], O. Rouvio[9], R. ruchlemr[10], A. Braester[11], D. Najib[12], C. Ganzel[10], A. Shaulov[13], U. greenboim[9], A. Polliack[3], T. Tadmor[14,*]
[1]The Ruth and Bruce Rappaport Faculty of Medicine, Technion, Haifa, [2] Department of Hematology, , Sourasky Medical Center, , Tel-Aviv, [3]Department of Hematology, Hadassah University Hospital, Jerusalem, [4]Department of Hematology, Rabin Medical Center, Petah-Tikva, [5]Department of Hematology, Meir Medical Center, Kfar-Saba, [6]Department of Hematology, , Kaplan Medical Center, , Rehovot, [7]Department of Hematology & Bone Marrow Transplantation, Rambam Health Care Campus, Haifa, [8]Hematology Unit, Emek Medical Center, Afula, [9]Department of Hematology, Soroka Medical Center, Beer Sheva, [10]Hematology Unit, , Shaare Zedek Medical Center, Jerusalem, [11]Hematology Unit, Galilee Medical Center, Naharia, [12]Hematology Unit, Ziv Medical Center, Zefat, [13]Internal Medicine , Hadassah University Hospital, Jerusalem, [14]Hematology uNIT, Bnai Zion Medical Center, Haifa, Israel

Background: Hairy cell leukemia (HCL) accounts for approximately 2% of all leukemias and is associated with pancytopenia, splenomegaly, and recurrent infections. Therapy with the purine analogues cladribine (2CdA) or pentostatin (2'deoxycoformycin), has been most effective and both agents have achieved equivalent results in HCL. In this regard cladribine given as a single course, achieves a high response rate. Several alternative dosing schedules have been reported for 2CdA including subcutaneous (SC) or intravenous (IV) delivery, either as a "fixed daily dose" or "weight based dose" for 5 or 7 days. Seeing that excellent results are obtained using 2CDA in all schedules used, it now seems very important to focus on reducing therapy induced toxicity, related mostly to development of neutropenia, immunosupression and severe infections.
Aims: In this retrospective study, we have summarized the Israeli experience with HCL over the past 30 years, and analyzed demographic data, relevant laboratory and clinical parameters with special emphasis on outcome after first line treatment with cladribine.
Methods: We collected retrospective data on patients with HCL from 12 medical centers in Israel, followed and treated during 1985-2015. The study was approved l by local institutional IRBs of each medical center
Results: Data from the medical records of 202 patients with HCL was summarized. Mean follow up was 7.5 years (0.1-40), with a 5 and 10 years' overall survival of 96% and 90.62% respectively. The median age at diagnosis was 53 years, and most (81.77%). were males. In terms of ethnicity: 88.3% of patients were Jews with (52.2% Ashkenazi and , 36.1% Sephardic Jews) while d 11.7% were Arab, Druz or others. First line therapy with cladribine was given to 159 patients (80.71%); other therapies 9.14%, while 1.1% did not receive any treatment. The median time from HCL diagnosis to treatment with 2CdA was 5.9 years. IV therapy was given to 62% of patients and 38% received it SC. Complete remission rates, progression-free survival and overall survival were not significantly different between the two schedules. In univariate analysis: Sex, ethnicity, dose, patient weight, and treatment duration (5-7 days) had no impact on outcome, but patients older >65 years had a shorter survival. Infectious complications requiring hospitalization was reported in 50.3% of all treated patients (54%, post IV and 47% post SC delivery: p=0.4). Median days of hospitalization were 8 for both groups (0-45) (p=0.55), and the length of NADIR was 18 and 20 days for IV and SC delivery respectively (p=0.33).
Summary/Conclusions: This study is the first comprehensive summary of the national Israeli experience involving a large cohort of HCL patients with long follow up. These results serve as validation of previous reports relating to HCL and confirm that the excellent outcome achieved after a single course of treatment with 2CdA is independent of schedule and method of drug delivery. In addition, patient ethnicity was insignificant

PB1782

CHRONIC LYMPHOCYTIC LEUKEMIA: CHANGES IN CLINICAL STAGE DISCRIMINATE PATIENTS WITH DIFFERENT OUTCOME WITHIN THE IWCLL PARTIAL RESPONSE CATEGORY

E. P. Vicente[1,2,*], M. Martínez[3], A. Soler[3], C. Cuellar[1], A. Mora[1,2], R. Bosch[1,2], J. Nomdedeu[4], I. García[1], A. Esquirol[1], M. Granell[1], S. Saavedra[1], J. Sierra[1], R. Martino[1], C. Moreno[1,2]
[1]Department of Hematology, [2]Laboratory of Oncology/Hematology and Transplantation, Institute of Biomedical Research, IIB Sant Pau, Hospital Sant Pau, [3]Department of Hematology, Hospital Parc Taulí, [4]Laboratory of Hematology, Hospital Sant Pau, Barcelona, Spain

Background: Over the last decades, progress in chronic lymphocytic leukemia (CLL) treatment has resulted in an impressive increase in overall survival (OS). In CLL, as in other tumors, response to therapy overcomes negative prognostic factors and is the most important predictor of survival. Clinical stages reflect tumor load and correlate with OS both at diagnosis and over the course of the disease (Rai et al, Blood 1975).
Aims: To determine whether changes in clinical stage discriminate patients with different outcome within IWCLL response categories, particularly the heterogenous partial response (PR) group (Hallek et al, Blood 2008).
Methods: Two-hundred twenty-nine patients with CLL were retrospectively evaluated. Median follow-up was 91 months (range, 2-390). CLL diagnosis was based on IWCLL criteria. Endpoints were time to next treatment (TTT) and OS. TTT and OS curves were estimated by the Kaplan-Meier method and differences were evaluated with the log-rank test. Response to therapy was determined according to IWCLL recommendations and by changes in clinical stage A landmark analysis was performed in ninety-two patients in whom a PR was achieved at any time during the course of the disease, using the time when a PR was achieved as "time 0".
Results: From the whole series of 229 patients, those who achieved a better IWCLL degree of response after first line of therapy had a better OS than those with an inferior response (p<0.001). With a median follow up of 91 months (range, 2-390), the median survival in patients who achieved complete remission (CR) was 214 (95% CI: 123-305) *vs* 134 (95% CI: 79-189) and 91 (95% CI: 84-98) months in those who achieved PR and failed to therapy, respectively (Figure 1.A). Among patients in PR (n=66), after a median follow-up of 42.5 months (range 1-201), those patients with stage A disease at the time of response evaluation (PR Binet A) had significantly better outcome than those whose stage was Binet B/C (median survival 63 *vs* 43 months; p= 0.047). Interestingly, when the analysis was restricted to response assessment after first line therapy (n=229), patients who achieved PR Binet A did not have significant differences in OS compared to those patients who were in CR (median survival were 164 and 214 months respectively; p<0.001); on the contrary, patients in PR Binet B/C had a similar outcome than those who did not respond to treatment (median survival 81 and 91 months respectively) (Figure 1.B). Similar results were observed in the outcome of patients with PR subclassified according to Rai clinical stage.

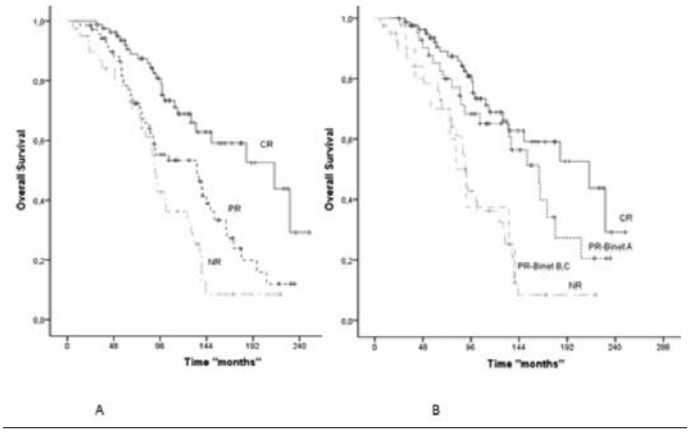

Figure 1.

Summary/Conclusions: Changes in clinical stage provide reliable information on the degree of response to therapy in patients with CLL, particularly those in the IWCLL PR category. This study supports the use of clinical stages as a complementary and simple tool to assess response in patients with CLL, both at the end and over the course of treatment.

PB1783

INCIDENCE OF THYROID GLAND DISORDERS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

A. Tombak[1,*], M.A. Ucar[1], R. Gen[2], M.A. Sungur[3]
[1]Hematology, [2]Endocrinology, Mersin University, Mersin, [3]Biostatistics, Duzce University, Duzce, Turkey

Background: Frequency of autoimmune complications like immune anemia or immune thrombocytopenia has increased in patients with chronic lymphocytic leukemia (CLL). However, there is no data in the literature investigating the relation of the other autoimmune disorders including thyroid gland diseases with CLL.
Aims: We aimed to investigate the presence, features and frequencies of thyroid disorders in patients with CLL.
Methods: Thyroid function tests, thyroid autoantibodies (antithyroglobulin antibody [anti-TG], antithyroid peroxidase antibody [anti-TPO]), thyroid ultrasonographies (USG) and scintigraphies of CLL patients were performed. Demographic data, Rai-stages, and established thyroid disorders were recorded.
Results: One hundred CLL patients were included into the study (65 male, mean age was 62,9±10,4). Free T3 (fT3) was within normal limits in 96 cases (96%), was low in 2 cases (2%), was high in 2 cases (2%); free T4 (fT4) was normal within normal limits in 89 cases (89%), was low in 7 cases (7%), was high in 4 cases (4%).TSH was within normal limits in 90 cases (90%), was low in 7 cases (7%), was high in 3 cases (3%). Anti-TPO and anti-TG were positive in 10 cases (11.8%) and in 18 cases (21.2%), respectively. While USG was normal in 36 cases, multinodular goiter (MNG) in 21, chronic thyroiditis in 20, MNG associated with thyroiditis in 10, uninodular goiter (UNG) in 8, UNG associated with thyroiditis in 4, and diffuse goiter in 1 case were determined by USG. Toxic adenoma in 3 cases, toxic MNG in 2 cases, and thyroiditis in 1 case were determined in 6 patients in whom thyroid scintigraphy was performed for hyperthyroidism. After evaluation of all the tests; while no thyroid disease was determined in 33 of the cases (33%), MNG in 25 (25%), thyroiditis according to the results of USG in 12 (12%), UNG in 11 (11%), Hashimoto thyroiditis in 9 (9%), toxic MNG in 3 (3%), subclinical hyperthyroidism in 3 (3%) cases, subclinical hypothyroidism in 1 case (1%), lymphocytic thyroiditis in 1 case (1%), toxic UNG in 1 case (1%), and euthyroid sickness syndrome in 1 case (1%) were determined. The patients were divided into 2 groups according to their Rai-stages and ages. Accordingly; Rai-stage 0 - I - II (n=80) and Rai-stage III - IV (n=20), <65 years (n=56) and ≥65 years (n=44). Anti-TPO positivity was similar in 2 Rai-stages groups and in both sexes (p=0,999, p=0,167, respectively). Anti-TG positivity was also similar in 2 Rai-stages groups and in both sexes (p=0,507, p=0,223, respectively). However, anti-TPO positivity was statistically different between age groups; anti-TPO was positive in 3 patients in <65 years old age group, and was positive in 7 patients in ≥65 years old age group (p=0.049). Anti-TG was positive in 7 patients in <65 years old age group,

and was positive in 11 patients in ≥65 years old age group (p=0.053). There was not a statistically difference in thyroid function tests according to the Rai-stages, ages and sexes.
Summary/Conclusions: We determined that incidence of hypothyroidism or hyperthyroidism associated with all reasons do not increase in patients with CLL when compared with general population. However, we also determined that the incidence of Hashimoto thyroiditis was higher than general population (incidence of Hashimoto thyroiditis in general population is 2-5%). Anti-TG positivity was also higher than general population (positivity of anti-TG in general population is 5-20%). In addition, the positivity of 2 antibodies increased with advanced ages. Patients with CLL -especially the elderly cases- in both sexes and in all Rai-stages should be examined for thyroid gland disorders, mainly for Hashimoto thyroiditis.

PB1784

CLINICAL-BIOLOGICAL CHARACTERISTICS, TREATMENT OUTCOME AND SURVIVAL OF SMALL LYMPHOCYTIC LYMPHOMA PATIENTS: A REAL-LIFE EXPERIENCE

S. Sachanas[1,*], G. Pangalis[1], M. Moschogiannis[1], C. Kalpadakis[2], M. Angelopoulou[3], C. Kyrtsonis[3], V. Bartzi[3], X. Yiakoumis[1], E. Koulieris[1], P. Tsirkinidis[1], M. Psyllaki[4], H. Papadaki[4], P. Korkolopoulou[5], D. Rontogianni[6], T. Vassilakopoulos[3]
[1]Hematologic, Athens Medical Center,Phychikon Branch, Athens, [2]University Hospital, University of Crete, Heraklion, [3]Hematologic, Laikon General Hospital, University of Athens, Athens, [4]Hematologic, University Hospital, University of Crete, Heraklion, [5]Pathology, Laikon General Hospital, University of Athens, [6]Pathology, Evangelismos General Hospital, Athens, Greece

Background: Studies of B-SLL published to date have included heterogeneous groups of patients(pts) and did not use modern diagnostic criteria, or included pts who had in fact chronic lymphocytic leukemia. Outside the context of clinical trials, SLL pts are treated heterogeneously and thus there are no data concerning the impact of different treatment approaches on response and survival. In the updated WHO classification it is pointed out that there are a subset of cases with lymph node(LN) involvement by SLL in which proliferation centers(PCs) were not observed and pts in whom lymphadenopathy was <1.5 cm showing a better prognosis
Aims: To: a)record clinical, biological features and treatment strategy in a series of SLL pts diagnosed in our centers b)correlate clinicopathological characteristics and treatment with response and survival c)detect possible differences in terms of response and survival between SLL pts according to LN characteristics (size of LN and presence of PCs)
Methods: Pts diagnosed with SLL from 2007 up to now fulfilling the diagnostic criteria of SLL according to the 2008 WHO classification were included. Clinical and biological data were recorded at diagnosis as well as treatment related variables, such as type of treatment, response and patient survival. Moreover, LN features such as the size, and the presence of PCs were also studied. PCs were evaluated in hematoxylin and eosin sections and defined as pale areas containing prolymphocytes and paraimmunoblasts, surrounded by a dark background of small lymphocytes.
Results: 47 pts were analysed. Pts' median age was 69y (range, 40–87) with no gender predominance (24male/23female). According to Binet staging system 12, 19 and 9 were classified as A, B and C stage respectively while according to Ann Arbor system 42(89%) had advanced disease stage. 11 pts presented with bulky lymphadenopathy, 11 had splenomegaly and 4 had B-symptoms. LN biopsies were performed in 37 out of 47 pts. All pts underwent bone marrow (BM) biopsy with a median BM infiltration of 45% (0-97%). PCs were identified in 19 out of 24 pts in whom data were available, while 31 pts were presented with LN >1,5 cm as measured in CT. The estimated 10 y -OS was 60% while median TFS was 5,3 mos. Age and ECOG performance status were the only parameters that were statistically significant in terms of survival (p=0,019 and p=0,013 respectively). Pts with LN<1,5cm and pts in whom there were no detectable PCs tended to have better survival. 24 pts (51%) were in need of therapy and most of them were treated with mild immunochemotherapy [13 received Rituximab(R)-Chlorambucil(Chl), 3 RCVP, 2FCR, 1RBendamustine, 2 Chl, 2R as monotherapy and 1 received corticosteroids].23 pts were assessable for response and among them 4 entered CR,17 PR and one had stable disease.
Summary/Conclusions: Outside the context of clinical trials SLL pts were treated mostly with lymphoma immunochemotherapeutic protocols while mild treatment approaches resulted in significant responses. LN features such as size and presence of PCs tended to have prognostic significance. Further analysis in larger series of pts is on the way.

PB1785

HEMINSIGHT TO ASSESS PATIENT REPORTED OUTCOMES O F PATIENTS AFFECTED BY CHRONIC LYMPHOCYTIC LEUKEMIA IN DAILY CLINICAL PRACTICE

G. Reda[1], B. Fattizzo[2,*], R. Cassin[1], E. Saluzzi[2], E. Flospergher[2], V. Mattiello[2], M. Sciumè[1], E. Ferretti[1], C. Andersen[3], E. Oliva[4], A. Cortelezzi[2]
[1]Oncohematology Department, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico of Milan, Italy, [2]Oncohematology Department, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, Italy, Milan, Italy, [3]Department of Hematology Roskilde University Hospital, Roskilde, Denmark, [4]Azienda Ospedaliera "Bianchi Melacrino Morelli", Reggio Calabria, Italy, Reggio Calabria, Italy

Background: Chronic lymphocytic leukaemia (CLL) is the most common leukemia in Western Countries, with a median age at diagnosis between 67 and 72 years. The therapeutic landscape of CLL is changing rapidly with the advent of small molecules acting as B-Cell Receptor (BCR) signaling inhibitors. In this setting, long term oral therapy may lead to the reduction in compliance, with a possible impact on effectiveness. Moreover, long-term follow-up may highlight complications, such as drug-related adverse events that, together with the disease itself, may impact quality of life (QoL). Patient Reported Outcomes (PROs) in daily clinical practice is a resource-intensive procedure and may be affected by low adherence, risk of recall bias and difficulties in establishing reproducible procedures. HemInsight, a project conceived in 2010 for myeloproliferative neoplasms in haematological centres in Denmark, enables patients to periodically submit PROs online to be combined to the medical records.
Aims: HemInsight was implemented at our Centre to collect PROs from CLL patients in daily practice.
Methods: HemInsight incorporated the EORTC QLQ-C30, EORTC QLQ-CLL 16, SF-36, and the eight-item Morisky Medication Adherence Scale (MMAS-8) questionnaires to collect PROs and their changes during various stages of CLL (diagnosis - progression – treatment). PRO assessments were scheduled for the patients who received regular reminders by email to complete the tasks. The following measurements will be assessed: system attraction (percentage of CLL patients adhering to the project); patient compliance in filling out questionnaires; system efficiency (number of alerts related to QoL worsening and number of questionnaires not submitted) and system effectiveness (significant differences in changes in QoL scores from diagnosis to response/relapse, changes of therapeutic approach/action following an alert, changes in adherence of therapy).
Results: At the time of the present report, 74 patients with a CLL diagnosis have been enrolled, 15 of whom were newly diagnosed. Fourteen patients underwent cytoreductive therapy and 2 are under treatment with novel oral drugs. System attraction: the study was proposed to 91 consecutive patients, independently of age, level of education and internet accessibility, and 72.5% of patients agreed to participate to the study. The main reason of refusal was older age and scant internet/technology knowledge. In 3 cases with no access to internet, but with interest to participate in the project, the questionnaires were administrated through tablet, before the scheduled visit, by a dedicated nurse. Patient compliance: a global response of 58.2% was observed; 48 patients responded at least once and 23 at all scheduled time points. In each case, all questionnaires were fully completed. At this timepoint we cannot yet evaluate system effectiveness as the study is still ongoing. However, *ad interim* data (Table 1) suggest that patients who interrupt questionnaires fulfilling are those with younger age, more intense working activity and experiencing no changes in disease status (*e.g.* untreated cases or those in remission). In particular, patients who were under treatment during the questionnaire administration period, showed a higher adherence compared to those in follow up, both previously treated or not (80% *versus* 26%, p<0.05).

Table 1.

PROs adherence according to treatment status in CLL patients

Adherence to PROs	Treatment naive	Previously treated	Under treatment	Total
No N(%)	17 (74)	6 (26)	0 (0)	23
Partial N(%)	19 (76)	5 (20)	1 (4)	25
Full N(%)	13 (59)*	5 (23)*	4 (18)*	22

PROs: patients reported outcome. *p<0.05

Summary/Conclusions: In conclusion, HemInsight is a useful tool for QoL evaluation in CLL patients. Provisional data suggest a higher compliance of those patients who feel that they need a closer contact with the clinician, both for individual disposition or disease status.

PB1786

HEALTHCARE COST OF MEDICARE PATIENTS WITH PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA

C. Reyes[1,*], G. Gauthier[2], L. Schmerold[3], A. Guerin[2]
[1]Genentech, Inc., San Francisco, United States, [2]Analysis Group, Inc., Montreal, Canada, [3]Analysis Group, Inc., New York, United States

Background: Chronic lymphocytic leukemia (CLL) is the most prevalent form of leukemia in adults in western countries, accounting for 20% to 30% of all leukemia cases. CLL affects mainly elderly patients, with a median age at the time of diagnosis reported to be 71 years. Although CLL is not curable, disease symptoms and progression may generally be controlled with adequate pharmacologic treatments. Bendamustine-based regimens have long time been used in the management of CLL patients but few studies have analyzed the comorbidity- and/or adverse event (CAE)-related healthcare costs in elderly patients receiving these regimens in a real-world setting.
Aims: To describe all-cause and CAE-related healthcare costs of elderly patients with CLL treated with a bendamustine-based regimen in second or later lines of therapy in a real-world setting.
Methods: A retrospective cross-sectional cohort study design was used. Adult patients who received a bendamustine-based regimen in second or later lines of therapy on or after January 2010 were identified from the Medicare Limited Data Set (LDS) 5% Standard Analytic Files (data availability: 1999–2014). The index date was defined as the initiation date for the first of the studied bendamustine-based regimens. Selected patients were required to be continuously enrolled in their Medicare plan for ≥6 months before and ≥3 months after the index date – unless the patient died during the first 3 months after the index date. Patient cohorts were determined based on the treatment initiated on the index date (index treatment); the two most prevalent bendamustine-based regimens were analyzed, *i.e.*, (1) bendamustine and rituximab in combination (BR cohort) and (2) bendamustine monotherapy (bendamustine cohort). Healthcare costs, including inpatient, emergency room, outpatients and CLL-drug costs, incurred while treated with the index treatment were described for each cohort. For each medical cost component, all-cause and CAE-related costs were summarized. Healthcare costs were adjusted for inflation (2016 USD) and reported per-patient-per-month (PPPM).
Results: A total of 275 patients were included in the BR cohort and a total of 100 patients in the bendamustine cohort. Most patients (61,8% in the BR cohort and 65,0% in the bendamustine cohort) were male and the mean age was approximately 75 years old. During the 6 months prior to the index date, patients in the BR and bendamustine cohorts were similar in terms of commorbidity profile; mean Charlson comorbidity index was 3.53 in the BR cohort *versus* 3.66 in the bendamustine cohort (p=0.580). During treatment, total all-cause healthcare costs were $14,520 PPPM for the BR cohort and $13,125 PPPM for the bendamustine cohort – outpatient costs (mainly driven by CLL-drug costs) represented the largest cost component. CAE costs accounted for a relatively large portion of the total all-cause healthcare costs; 58.3% for the BR cohort and 66.9% for the bendamustine cohort.
Summary/Conclusions: In this population of elderly patients previously treated for CLL, healthcare costs incurred during relapsed treatment with bendamustine-based regimens were high and a large portion of the costs were driven by comorbidity and/or adverse event-related costs. Results also suggest that the addition of rituximab to bendamustine does not appear to be a major cost factor.

PB1787

THE ROLE OF MAINTENANCE THERAPY IN THE TREATMENT OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

A. Kuvshinov[1,*], S. Voloshin[1], I. Martynkevich[1], A. Garifullin[1], E. Kleina[1]
[1]Russian Scientific Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: The inclusion in the treatment program of new drugs (including new monoclonal antibodies and targeted therapies) allowed the majority of patients with chronic lymphocytic leukemia (CLL) to achieve disease remission (complete or partial) after combined therapy. So, at now, the urgent task is long-term preservation and the deepening of the therapeutic response, if it is possible. This problem can be solved by intensification of therapy (including autologous transplantation of hematopoietic stem cells) or maintenance therapy (MT).
Aims: To estimate the importance of maintenance therapy in the treatment of patients with CLL.
Methods: The study included 198 patients. Male to female ratio - 1.3:1. We have used NCI revised guidelines (Hallek M, *et al.*, 2008) for treatment initiation, assessment of response and minimal residual disease (MRD). Induction chemotherapy was conducted under the following programs: RB, FC, RFC, R-CHOP, Ibrutinib-RB, Ibrutinib-R. Evaluation of MRD was performed using 5-color flow cytometry of the bone marrow cells. The maintenance therapy was conducted 144 (72.7%) patients: Rituximab 500 mg/m2 intravenously every 8 weeks (n=116) for 2 years; Ibrutinib 420 mg, orally, daily (n=28) continuously. The remaining patients (n=54) were under dynamic observation without therapy.
Results: The increasing the depth of response (from partial (PR) to complete remission (CR)) was observed only in group of patients receiving MT – 10.4% (15/144) (p=0.013). The frequency of increase the depth of remission in the patients treated with MT of Ibrutinib was 28.6% (8/28), MT of Rituximab – 6.0% (7/144) (p=0.0005). The medians of PFS and duration of response were a longer in the patients with MT *versus* in the patients without MT: PFS – 48 months and 37 months, respectively (p=0.03); duration of response – 44.0 months and 25.5 months, respectively (p=0.0006). The median of duration of response in the patients with MT of Ibrutinib was not reached, in the patients with MT of Rituximab – 41.9 month, in the patient without MT – 25.5 month (p=0.004). The frequency of relapses in the group of patients with MT was 39.6% (57/144), in the group of patients without MT – 66.7% (36/54) (p=0.0007). Recurrence of the disease occurred more frequently in the group of patients treated with MT of Rituximab, compared with Ibrutinib: 45.7% (53/116) and 14.3% (4/28), respectively (p=0.002). The median duration of observation in the group with rituximab was 22 months, while in the group with Ibrutinib – 11 months. MRD was not detected after 6-12 months of MT in 23.5% (12/51) had previously MRD-positive patients. Among patients with MRD-negative CR relapse is less common than in patients with MRD-positive CR – 20.0% (4/20) *versus* 62.5% (10/16), respectively (p=0.009). Significant differences in the incidence of infectious complications between patients with MT and without of MT were not detected (p>0.05) (Figure 1).

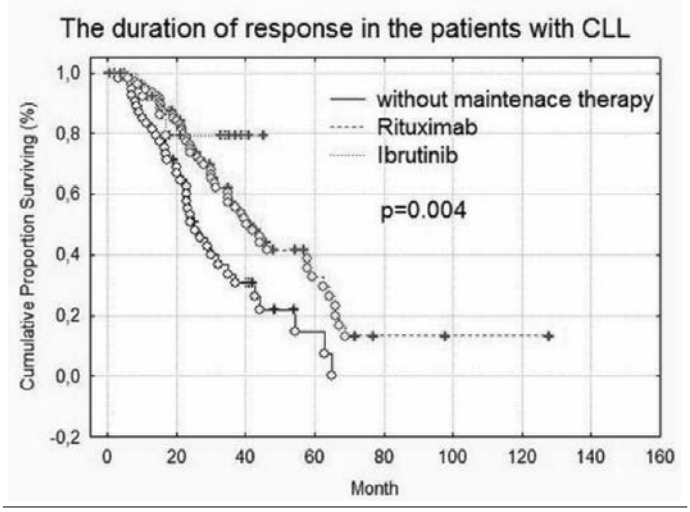

Figure 1.

Summary/Conclusions: The conducting of MT patients with CLL allows to achieve increasing the depth achieved remission and increase the duration of its preservation. MT may be a means of control over the minimal residual disease and the method of its eradication

PB1788

MULTISITE PERFORMANCE EVALUATION STUDY OF THE BD ONEFLOW LYMPHOID SCREENING TUBE

B. Balasa[1,*], C. Green[2], J. Kendall[2], D. Gladding[2], C.J. Fox[2], D. Van Hoof[2], V. Fraser[2], A. Doherty[3], D. Tielemans[4], L. Wolfe[5], K. Judge[2]
[1]Medical Affairs, [2]BD Biosciences, San Jose, United States, [3]BD Biosciences, Oxford, United Kingdom, [4]BD Life Sciences, Erembodegem, Belgium, [5]BD Clinical Corporate Clinical Development, Sparks, Maryland, United States

Background: The BD OneFlow solution for diagnostic screening of chronic lymphoproliferative disorders (CLPDs) includes a standardized flow cytometry approach based on the EuroFlow (EF) Consortium liquid reagent system. The BD OneFlow solution enables reproducible identification and discrimination of normal from aberrant mature cell populations by combining standardized assays, setup reagents, and protocols. The BD OneFlow LST (Lymphoid Screening Tube) is intended for flow-cytometric immunophenotyping of normal and aberrant mature lymphocyte populations of B, T, and NK lineages in specimens (peripheral blood, bone marrow, and lymph node) from patients with hematological disorders. BD OneFlow LST acquisition and analysis template version 1.0 was revised to version 2.0 to include determination of lymphocytes as a percentage of total leucocytes. The FCS files from evaluable specimens of the original LST clinical trial were regressed using BD OneFlow LST template v2.0.
Aims: The objective of this study was to regress the FCS files from all the evaluable specimens previously collected using LST template v1.0 in the original clinical study to demonstrate equivalency between the investigational BD OneFlow LST system and the comparator EF liquid reagent system on a BD FACSCanto II flow cytometer with the 4-2H-2V CE-IVD configuration and LST template v2.0.
Methods: The FCS files using LST v1.0 template from the original clinical study included de-identified remnant peripheral blood (n=123), bone marrow (n=53), and lymph node (n=31) specimens from patients and healthy donors. Specimens

were collected in EDTA or heparin anticoagulants or PBS (for lymph nodes) at three external study sites. Informed consent was not required in this clinical study. All specimens in the original study were simultaneously stained with investigational BD OneFlow LST and comparator EF liquid reagents within 24 hours of collection and were acquired within 60 minutes of staining. In the current study, analyses were performed on a BD FACSCanto II instrument using LST v2.0 template with BD FACSDiva software v8.0.1. For primary endpoints, specimens were categorized as normal or follow-up needed. If follow-up was needed, specimens were categorized as B-, T-, NK-, or other-cell lineage. Overall agreement, negative agreement, and positive agreement, along with their one-sided lower 95% confidence limits, were calculated. For quantitative (percent) comparison of defined cell populations, Deming regression (slope and intercept analysis) was performed between the BD OneFlow method and the EF method.
Results: The BD OneFlow LST system compared to the EF system gave 100% (207 of 207) overall agreement (lower 95% CI: 98.6%) in delineating patients into normal (no follow-up) or follow-up, and 100% overall agreement in identifying the B-, T-, NK-, and other-cell lineages (lower 95% CI: 98.6%). There was 100% positive agreement and 100% negative agreement between BD OneFlow and EF for follow-up *vs* no-follow-up (normal) and for all cell lineages from specimens that required follow-up. Furthermore, compared to the EF system, the BD OneFlow LST system met the acceptance criteria for the quantitative assessment (Deming regression) of the defined cell populations.
Summary/Conclusions: The multisite performance evaluation of the BD OneFlow LST system and the comparator EF liquid reagent system was concordant in identifying abnormal from normal mature populations in patients with CLPDs. BD OneFlow LST is for *in Vitro* Diagnostic Use; CE Marked to the European *In Vitro* Diagnostic Medical Device Directive 98/79/EC. 23-19566-00.

IMMUNOGLOBULIN HEAVY/LIGHT CHAIN ASSAY DETECT IMMUNE DYSREGULATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

L. Magal[1], A. Braester[2], D. Najib[3], A. Aviv[4], Y. Herishanu[5], M. Yuklea[6], L. Shvidel [7], N. Rahimi-Levene[8], R. Ruchlemer[9], A. Arad[10], A. Polliack[10], T. Tadmor[11,*]
[1]Almog Diagnostic, Park Shoham, [2]Hematology Unit, Galilee Medical Center, Naharia, [3]Hematology Unit, Ziv Medical Center, Zefat, [4]Hematology Unit, Haemek Medical Center, Afula, [5]Department of Hematology, Sourasky Medical Center, Tel Aviv , [6]Hematology Unit, Meir Medical Center, Kfar Saba, [7]Hematology Unit, Kaplan Medical Center , Rehovot, [8]Hematology Unit, Assaf Harofeh Medical Center, Zerifin, [9]Department of Hematology, Shaare Zedek Medical Center, [10]Department of Hematology, Hadassah University Hospital, Jerusalem, [11]Hematology Unit, Bnai-Zion Medical Center, Haifa, Israel

Background: Chronic lymphocytic Leukemia (CLL) is frequently accompanied by immune dysregulation. Hypogammaglobulinemia is the most important associated immune defect and all three classes of immunoglobulins (IgG, A and M) are involved. Recently, a novel assay for detecting heavy/light chain (hevylight) and their ratios has been described (HLC), which improves immunoglobulin detection and monitoring in plasma-cell dyscrasias by quantitating the different light chain types of each immunoglobulin class. The frequency and biological role of this assay has as yet not been studied in CLL.
Aims: To study the frequency of abnormal Heavy Light chain assay, in CLL patients.
Methods: This is an observational, multi-center study performed in collaboration with the Israeli CLL Study Group involving 10 medical centers in Israel. The cohort included patients with CLL as well as healthy volunteers**.** All patients studied had complete clinical database available and all medical records were examined and then summarized. Serum samples were analyzed for levels of: IgG1, IgG2, IgG3, IgG4. Isoforms of heavy/light chain: IgG kappa, IgG lambda, IgA kappa, IgA lambda, IgM kappa, IgM lambda and Free light chain: kappa (K) and lambda (L), ratio of K/L and calculation of ratios of monoclonal/polyclonal immunoglobulin (HLC ratio).
Results: The total cohort consisted of 126 "treatment - naïve", patients with CLL and 26 healthy volunteers**.** Median age was 64 years, 64% were males and 78% had Binet stage A, while 19% and 3% were stages B or C respectively. Significantly reduced levels of immunoglobulins associated with lambda chain (IgG-L, IgA-L and IgM-L) were identified in CLL patients compared to healthy controls (p value of 0.001, 0.005 and 0.001 respectively). Abnormal IgG-lambda values were evident in 15 patients (10%) and associated with more pronounced leucocytosis (p=0.005), higher B2mg levels (p=0.022) and the presence of 17p deletion (0.028). IgA and IgM lambda were abnormal in 38% and 56% of cases respectively compared to 8 and 9% in the controls. For IgG subclasses: both IgG2 and IgG4 levels were significantly lower in CLL patients than in healthy controls (p= 0.001 and p<0.01 respectively). In addition , IgG2 and IgG4 were also confirmed to be significantly lower in CLL patients than in controls (p<0.001), while abnormal IgG2 levels were associated with more advanced Binet stage and elevated LDH levels. Abnormal lambda FLC was observed 26 (21%) patients and only in one (4%) healthy control. Abnormal free light chain ratio (FLC) was present in 39 patients (32%), with a mean value of 4.22 (0.11-62.15) while only 1 (4%) was observed in healthy controls (mean value of 1.76 (0.25-2.3)) and was also associated with more advanced Binet stage and elevated LDH (p=0.003.).
Summary/Conclusions: CLL cells may produce light chains, or as shown here abnormal intact immunoglobulins (heavy and light chains). HLC levels were associated with advanced stage and adverse prognostic parameters. These findings lend support for the considerable potential of the HLC assay in the evaluation of clinical status in patients with CLL

PB1790

INFLUENCE OF TREATMENT ON CONCENTRATION OF CYTOKINES IN BLOOD OF PATIENTS WITH HAIRY CELL LEUKEMIA

N. Pelenyo[1,*], V. Barilka[1], V. Matlan[2], O. Danysh[1], Y. Vygovska[1], Z. Maslyak[1], O. Shalay[1], V. Loginsky[1]
[1]SI "Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine", [2]Danylo Halytsky Lviv National University, Lviv, Ukraine

Background: A pathogenic role and prognostic value of cytokines in treatment of patients (pts) with hairy cell leukemia (HCL) are not finally established.
Aims: to define the concentration of cytokines such as TNFα, IL-6, sIL-2R, TGFβ1 in serum of HCL pts before and after treatment with IFNα or 2-CdA and to estimate the relationship with blood count indexes in HCL pts.
Methods: The study group consisted of 26 primary pts with the classic variant of HCL (median age - 47 years). A control group consisted of 12 healthy persons (median age - 50 years). The concentration of cytokines was measured using a validated commercial ELISA kits.
Results: Median of TNFα content in serum of HCL pts before treatment was substantially lower (3.57 pg/ml) than in healthy persons (8.56 pg/ml; p=0.275), however treatment with IFNα or 2-CdA did not influence TNFα level. Median of TGFβ1 concentration in serum of HCL pts was also significantly lower, than in healthy persons (265.52 and 1568.22 pg/ml respectively; p=0.0004). Reliable increase of TGFβ1 concentration was observed only after 2-CdA therapy (928.33 pg/ml; p=0.281). Cross-correlation relationship was revealed between the TGFβ1 concentration and the level of haemoglobin (τ=0.23; p=0.1) as well as with leucocyte count in HCL pts (τ=0.24; p=0.09). Median of IL-6 content in serum of HCL pts before treatment was higher, than in healthy persons. Therapy with IFNα or 2-CdA reduced IL-6 level to the control values. Certain cross-correlation relationships were revealed between the IL-6 level and percentage of lymphocytes in bone marrow (τ=0.35; p=0.01) as well as amount of lymphocytes in peripheral blood of HCL pts (τ=0.24; p=0.09). Median serum concentration of sIL-2R (24.73 ng/ml) in HCL pts more than 20-fold exceeded such in control group (1.15 ng/ml; p=0.0000005). Cross-correlation relationship was revealed between the percentage of hairy cells in bone marrow and sIL-2R level in serum (τ=0.27; p=0.08). Obtained results may be an evidence of predominant secretion of sIL-2R by tumor cells in HCL pts.
Summary/Conclusions: New data regarding pathogenetic relationship between production of certain cytokines and features of hematopoiesis in HCL pts was obtained. Between the blood level of some cytokines in HCL pts and efficiency of 2-CdA treatment a reliable relationship was revealed, which is possible to use for prediction of clinical course of this disease. Moreover sIL-2R level in blood possibly can serve as a marker of tumour activity in classic type of HCL.

PB1791

PROGRESSION-FREE SURVIVAL AND OVERALL SURVIVAL IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA – CLINICAL BENEFITS OF ACHIEVING A DEEP RESPONSE TO FIRST-LINE THERAPY

J. Samp[1,*], A. Guerin[2], R. Foster[3], B. Meissner[1], A. Rokito[3], S.H. Enschede[1], G. Gauthier[2]
[1]AbbVie, Inc., North Chicago, United States, [2]Analysis Group, Inc., Montreal, Canada, [3]Analysis Group, Inc., New York, United States

Background: In recent years, there have been advances in the treatment of CLL with the approval of several novel oral agents that show improvement in PFS and OS. Additionally, some agents induce a deep response indicated by complete remission (CR) and/or minimal residual disease negativity (MRD-). However, there is limited information on the longer-term clinical benefits of achieving a deep response in a real-world setting.
Aims: This study aimed to characterize PFS and OS for patients who achieved a deep response to first-line therapy for CLL.
Methods: Patient-level data were collected between July and August 2016 from 93 oncologists/hematologists in the United States. Oncologists/hematologists provided patient level clinical data obtained from patient charts among CLL patients who initiated first-line therapy for CLL between January 2010 and December 2014. Selected patients were categorized into 2 cohorts based on their best response: patients who achieved CR and patients who did not achieve CR (non-CR). The non-CR cohort included patients with partial remission (PR), stable disease (SD) and progressive disease (PD). iwCLL 2008 criteria were provided to guide physicians' assessment of treatment response. The target sample size for each response type was *a priori* determined based

on distribution of response in clinical trials. Data on disease progression and mortality was provided by the treating oncologist/hematologist. PFS and OS were compared using univariate and multivariate Cox proportional analyses between the CR and non-CR cohorts (OS multivariate analyses were not conducted due to the small number of events). An additional analysis was conducted to examine the benefits of achieving MRD- *versus* not achieving MRD- among patients who achieved CR or PR.

Results: Data was collected on 330 CLL patients, including 179 patients in the CR cohort and 151 patients in the non-CR cohort (120 patients with PR, 25 with SD, and 6 with PD). Most patients were male, in their early sixties, and had an ECOG status of O/1 at the time of initiating first-line therapy. The median observation period was approximately 30 months. There were 43 (24%) patients in the CR cohort and 75 (50%) patients in the non-CR cohort who progressed/died (Table 1). Patients in the non-CR cohort had an >2-fold higher hazard of progression/death (adjusted hazard ratio [HR]=2.30, p<0.05) and death (unadjusted HR=2.61, p<0.05) compared to patients in the CR cohort. Among patients who achieved CR or PR, 84 patients achieved MRD- and 62 patients did not; 14(17%) patients who achieved MRD- and 27 (44%) patients who did not achieve MRD- progressed/died. Patients who did not achieve MRD- had an over three-fold higher hazard of progression/death compared to patients who achieved MRD- (adjusted HR=3.75, p<0.05). No death events were observed among patients who achieved MRD- while 4 (6%) events were observed among those who did not achieve MRD-.

Table 1.

Proportion of Patients with Progression/Death During the Observation Period

Event, N (%)	CR N= 179	Non-CR N=151	MRD- N=84	No MRD- N=62
Progression/Death	43 (24%)	75 (50%)	14 (17%)	27 (44%)
Progression	38 (21%)	69 (46%)	14 (17%)	23 (37%)
Death	7 (4%)	15 (10%)	0 (0.0%)	4 (6%)

Summary/Conclusions: Findings from this real-world study suggest that achieving CR is associated with improved PFS and OS compared to patients who do not achieve CR. Furthermore, significantly better outcomes were observed in patients who achieved MRD- compared to those who did not achieve MRD- but still achieved CR or PR. This suggests that deep response may be an important clinical parameter to consider in the treatment of CLL.

PB1792

ANTI-CD ANTIBODY MICROARRAY FOR MORPHOLOGY EXAMINATION OF CIRCULATING LEUKEMIA AND LYMPHOMA CELLS

S. Kuznetsova[1,2,*], A. Khvastunova[1], A. Zakirova[1], O. Fedyanina[12,]
[1]Centre for Pediatric hematology, oncology and immunology, [2]Centre for theoretical problems of physico-chemical pharmacology, Moscow, Russian Federation

Background: Matching the morphology with immunophenotype for individual leukocytes is a major issue in diagnostics of leukemia and lymphoma due to the absence of a method for simultaneous cluster of differentiation surface antigen detection and full leukocyte morphology analysis. This problem can be solved by using a leukocyte-binding antibody microarray.

Aims: We describe an anti-CD antibody microarray on a transparent support for leukocyte sorting and a method for preparation of the microarray-bound cells for high-resolution morphology analysis. The aim of the work was to demonstrate, that the leukocyte binding is highly specific and that the microarray-bound peripheral blood mononuclear cells both from healthy donors and patients with B-cell leukemias and lymphomas are morphologically identical to the same cells in blood smears.

Methods: Anti-CD antibodies were immobilised on plastic coverslips in spots 2 mm in diametre. In order to study the peripheral blood mononuclear cells (PBMC) the mononuclear fraction separated by density gradient from peripheral blood are incubated with the microarray in non-mixing conditions at 4 ^{0}C. After the unbound cells are washed away the microarray-bound cells are dried in a cytocentrifuge and stained after May-Grünwald-Giemsa for morphology examination. Using this technique we have studied the PBMC from 55 healthy donors and 77 patients with different leukemias and lymphomas: chronic lymphocytic leukemia (CLL, 37 patients), hairy cell leukemia (HCL, 22 patients), splenic marginal zone lymphoma (SMZL, 7 patients), mantle cell lymphoma (MCL, 2 patients), follicular lymphoma (FL, 1 patient), 5 patients with multiple myeloma (MM), 2 patients with large granular lymphocytic (LGL) leukemia and one patient with acute myeloid leukemia (AML M2).

Results: Nonspecific cell binding both inside and outside the spots is below 5%. Due to the non-mixing incubation the density of the cells bound to an anti-CD antibody permits to determine the proportions of cells positive for the corresponding CD antigen with high correlation with flow cytometry. The patterns of the binding densities of the anti-CD-captured PBMC for CLL, HCL and SMZL patients clearly differ both from those for normal PBMC and from each other and agree well with the reported immunophenotypes of corresponding neoplastic cells. Both normal and pathologic microarray-bound PBMC after the proprietary drying procedure are morphologically identical to the same cells in a smear. In cases when pathologic cells are morphologically and/or cytochemically distinct, the anti-CD antibody microarray permits to determine their percentage and immunophenotype by analysing the relative amount of these cells captured by the antibodies against all the CD antigens. The results of such analysis of neoplastic PBMC for the patients with leukemias and lymphomas agree with flow cytometry results for the same patients including expression of CD2 in HCL, CD2 and CD11c in CLL, CD56 in MM. The amount of hairy cells determined morphologically on the microarray varied from 20 to 97 of all anti-CD19-captured cells and 2 to 80% of all lymphocytes and was in good agreement with the percentages of cells with CD19/CD103 and CD19/CD11c coexpression determined in the peripheral blood of the same patients by flow cytometry.

Summary/Conclusions: The microarray works as a "sorted smear" with cells positive for certain surface CD antigens localised in a predetermined area and permitting to apply any standard smear-oriented technique to the microarray-captured cells. Combined analysis of the pathologic cells' immunophenotype, morphology and cytochemistry on the microarray permits to arrive at preliminary diagnosis and can be used in cases of any controversies between morphology, cytochemistry and immunophenotyping. The work is partially supported by 16-34-01030 and 16-04-00282 grants from RFBR.

PB1793

COMPARATIVE ANALYSIS OF INTERNATIONAL PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKEMIA, PROGRESSION-RISK SCORE AND MD ANDERSON CANCER CENTER 2011 SCORE: REAL WORLD DATA FROM A SINGLE INSTITUTION

V. Vukovic[1,*], D. Antic[1,2], T. Karan-Djurasevic[3], N. Milic[4], M. Todorovic-Balint[1,2], J. Bila[1,2], B. Andjelic[1,2], V. Djurasinovic[1,2], A. Sretenovic[1], M. Smiljanic[1], J. Jelicic[1], M. Dencic-Fekete[1], M. Perunicic-Jovanovic[1], N. Kraguljac-Kurtovic[1], S. Pavlovic[3], B. Mihaljevic[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Medical Faculty, University of Belgrade, [3]Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, [4]Institute for Medical Statistics and Informatics, Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: In recent times, several powerful prognostic scores have been developed in order to predict time to first treatment (TTFT) and overall survival (OS) of patients with chronic lymphocytic leukemia (CLL). The international prognostic index for chronic lymphocytic leukemia (CLL-IPI) developed by The International CLL-IPI working group was found to predict OS and TTFT, while the rest of two scores- progression-risk score (PRS) and MD Anderson Cancer Center Score 2011 (MDACC 2011) have been developed for prediction of TTFT in early stage CLL patients.

Aims: The aim of this study was to compare CLL-IPI, PRS and MDACC 2011 prognostic scores based on their impact on TTFT, treatment response (TR), progression-free survival (PFS) and OS of 54 treated CLL patients.

Methods: We retrospectively analyzed data from 54 consecutive CLL patients diagnosed and treated at Clinic for Hematology, Clinical Center of Serbia from 2003 to 2013. Blood samples were prospectively collected and analyzed for biological and molecular features (IGHV, FISH and *TP53*), as well as standard laboratory parameters. The three scores were retrospectively calculated using formulas from the original articles (International CLL-IPI working group, Lancet Oncol 2016, for CLL-IPI; Gentile et al, Leukemia 2016, for PRS; and Wierda et al, J Clin Oncol 2011, for MDACC 2011 score), and, than, correlated with TTFT, TR, PFS and OS of patients from the studied cohort.

Results: Median age at diagnosis was 57 years (range 38-75). All patients were treated with fludarabin-based chemotherapy, 45 (83%) in the first treatment line. Overall response rate to the first line therapy was 81%, equally distributed on complete and partial responses. Most of the patients (42, 78%) relapsed during the follow up. At the time of the last follow up 14 (26%) patients were still alive, 35 (65%) were dead, and 5 (9%) were lost to follow up. Median overal survival was 76 months. Lower score values for all the three scoring systems (CLL-IPI, PRS, and MDACC 2011) correlated with longer TTFT (p<0.05 for all). Cox regression analysis revealed that CLL-IPI and PRS are significant predictors of TTFT (p=0.003, RR=1.4, 95%CI 1.1-1.7 and p=0.019, RR=1.4, 95%CI 1.1-1.9, respectively), while MDACC 2011 was of borderline significance (p=0.052). In the multivariable analysis PRS emerged as the most significant predictor of TTFT among the three examined scores (p=0.041, RR=1.35, 95%CI 1.01-1.81). Regarding TR, only PRS appeared to have borderline statistical significance (p=0.052), showing that patients with lower score value may achieve better TR. Lower CLL-IPI can predict longer PFS after the first line treatment (p=0.007, RR=1.7, 95%CI 1.2-2.57), as well as PRS (p=0.039, RR=1.8, 95%CI 1.03-3.1). MDACC 2011 has not shown to have influence on PFS. Multivariable analyisis confirmed PRS to have the strongest predictive value of all the three scores regarding duration of PFS (p=0.039, RR=1.8, 95%CI 1.02-3.1). Furthermore, CLL-IPI and PRS were found to be significant predictors of OS (p=0.005, RR=1.4, 95%CI 1.1-1.8 and p=0.037, RR=1.5, 95%CI 1.03-2.24, respectively).

Summary/Conclusions: CLL-IPI and PRS were identified as significant predictors of TTFT, as well as of duration of TR and OS. Further studies are warranted to confirm these findings.

PB1794

MULTISITE PERFORMANCE EVALUATION STUDY OF THE BD ONEFLOW B-CELL CHRONIC LYMPHOPROLIFERATIVE DISORDERS T1 (B-CLPD T1) PANEL

B. Balasa[1,*], C. Green[2], J. Kendall[2], D. Gladding[2], I. Racoma[2], D. Van Hoof[2], F. Oreizy[2], A. Chen[2], V. Fraser[2], A. Doherty[3], D. Tielemans[4], L. Wolfe[5], K. Judge[2]
[1]Medical Affairs, [2]BD Biosciences, San Jose, United States, [3]BD Biosciences, Oxford, United Kingdom, [4]BD Life Scienecs, Erembodegem, Belgium, [5]BD Clinical Corporate Development, Sparks, Maryland, United States

Background: The BD OneFlow solution for B-cell chronic lymphoproliferative diseases (B-CLPDs) incorporates a standardized flow cytometry approach based on the EuroFlow (EF) Consortium liquid reagent system. The BD OneFlow solution enables reproducible identification and discrimination of distinct cell populations by combining standardized assays, setup reagents, and protocols. The previously launched BD OneFlow LST (Lymphocyte Screening Tube) is intended for flow-cytometric immunophenotyping of normal (no follow-up required) and aberrant (follow-up required) mature lymphocyte populations of B, T, and NK lineages in specimens from patients with hematological disorders. The BD OneFlow B-CLPD T1 is being developed to work in conjunction with BD OneFlow LST for the immunophenotyping of B cells and distinguishing chronic lymphocytic leukemia (CLL) from other B-CLPDs such as atypical CLL, follicular cell lymphoma, mantle cell lymphoma, etc.
Aims: The objective of this study was to demonstrate equivalency (accuracy) between the investigational BD OneFlow LST and BD OneFlow B-CLPD T1 system and the corresponding comparator EF liquid reagent system on the BD FACSCanto II flow cytometer using BD FACSDiva software.
Methods: De-identified remnant peripheral blood (PB) (n=70) and bone marrow (BM) (n=31) patient specimens were collected in EDTA or heparin anticoagulants at four external study sites and tested within 26 hours of draw. Informed consent was not required in this clinical study. Specimens were stained with BD OneFlow LST in combination with OneFlow B-CLPD T1 tubes and comparator EF liquid reagents. Acquisition and analysis were performed on a BD FACSCanto II instrument using BD OneFlow LST and B-CLPD T1 templates in BD FACSDiva software v8.0.1. Categorization of samples with abnormal B-cell populations into CLL (typical) or other B-CLPDs, overall agreement, negative agreement, and positive agreement, along with their one-sided lower 95% confidence limits, were calculated. For qualitative categorization of relative fluorescence intensity (positive or negative) of the aberrant cell populations, overall agreement with one-sided lower 95% confidence limits was calculated.
Results: All evaluable specimens were identified by the OneFlow LST as having B-cell populations requiring follow-up by both methods. Compared to the EF system, the BD OneFlow LST in combination with the BD OneFlow B-CLPD T1 system gave 100% (101 of 101) overall agreement in classifying patients as having CLL (54 of 54 concordant) and in identifying patients with other B-CLPD diseases (47 out of 47 concordant) with a lower 95% CI of the overall agreement of 97.4%. The BD OneFlow B-CLPD T1 system, compared to the EF system, gave 100% (101 of 101 concordant) agreement for the qualitative assessment of the relative fluorescence intensity of CD45+CD19+ aberrant populations for CD20+, CD200+, and CD23+ subsets and 99.1% agreement for the CD79b+ subset.
Summary/Conclusions: The multisite performance evaluation between the BD OneFlow system (LST and B-CLPD T1) and the comparator EF liquid reagent system was concordant in distinguishing abnormal B-cell populations in patients with CLL from patients with other B-CLPDs, including presumptive cases of atypical CLL. The BD OneFlow B-CLPD T1 is a fully standardized and validated system for aiding in the diagnosis of CLL from other B-CLPDs in PB and BM specimens.
BD OneFlow LST and BD OneFlow B-CLPD T1 are CE Marked according to the European *In Vitro* Diagnostic Medical Device Directive 98/79/EC. 23-19567-00

COMBINED PATTERNS OF IGHV REPERTOIRE AND MOLECULAR ALTERATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA- SINGLE CENTER EXPERIENCE

S. Trajkova[1,*], L. Cevreska[1], A. Dimovski[2], M. Ivanovski[1], M. Popova-Labacevska[1], D. Dukovski[1], B. Kocoski[1], I. Panovska-Stavridis[1]
[1]Hematology, University clinic for Hematology, [2]Faculty of Pharmacy, University "Ss. Cyril and Methodius", Skopje, Macedonia, The Former Yugoslav Republic Of

Background: The specific determining factors for malignant progression in Chronic lymphocytic leukemia (CLL), remaining unknown.
Aims: To investigat the potential existence of unique cytogenetic profiles associated with specific IGHV repertoires that could be associated with an increased risk of progression in CLL.
Methods: For this purpose, molecular analysis of well-established cytogenetic alterations of chromosomes 11, 12, 13, 14 and 17 together with the pattern of rearrangement of the IGHV genes were performed in 100 CLL cases.
Results: Our results based on molecular analysis from 100 subjects living in the same geographical area, show the presence of three major groups of clones with distinct but partially overlying configurations of IGHV gene usage, IGHV mutational status and cytogenetic alterations. These included a group which mainly consisted of clinical advanced stage CLL with a skewed but different CLL-associated IGHV gene repertoire (VH1-69 associated with HD3 gene and HJ6 gene), frequently associated with complex karyotypes and poor-prognosis cytogenetic alterations , a second group enhanced in clones expressing specific IGHV subgroups (VH3-23 associated with HD2 genes and HJ6 gene) with no or isolated good-prognosis cytogenetic alterations and a third group of clones with intermediate features, with prevalence of mutated IGHV genes, and higher numbers of del(13q)+ clonal B-cells.
Summary/Conclusions: These findings suggest that the specific IGHV repertoire and IGHV mutational status of CLL B-cell clones may adjust the type of cytogenetic alterations acquired and their clinical significances. Further long-term follow-up studies investigating the IGHV gene repertoire of CLL clones in distinct geographic areas and microenvironments are required to validate our findings and discard or confirm the potential role of some antigen-binding BCR specificities contributing to clonal evolution.

PB1796

PROGNOSTIC SIGNIFICANCE OF SERUM BAFF, APRIL, TACI AND BCMA LEVELS IN CHRONIC LYMPHOCYTIC LEUKEMIA

I. Berke Mentese[1,*], Z.A. Yegin[2], S. Gokcen[2], Z.N. Ozkurt[2], M. Yagci[2]
[1]Internal Medicine, [2]Hematology, Gazı University Faculty of Medicine, Ankara, Turkey

Background: B-cell chronic lymphocytic leukemia (B-CLL) is characterized by the accumulation of $CD5^+$ B cells in the peripheral blood and bone marrow. Prognosis of B-CLL is highly variable which depends on certain prognostic parameters. Novel prognostic markers and risk assessment models are fundamental to identify high risk patients who may need early treatment. The two tumour necrosis factor family proteins BAFF (TNFSF13B) and APRIL (TNFSF13) and their receptors [BAFF-R (TNFRSF13C), TACI (TNFRSF13B), BCMA (TNFRSF17)] play a critical role in the survival of normal B cells.
Aims: In this study, we aimed to investigate the impact of serum BCMA, TACI, BAFF and APRIL levels on prognosis of B-CLL.
Methods: A total of 129 newly diagnosed CLL patients [median age: 64(39-88); M/F: 85/44] and 26 healthy volunteers were enrolled in this study. Serum BCMA, TACI, BAFF and APRIL levels were measured at diagnosis using enzyme-linked immunosorbent assay (ELISA). The association with conventional prognostic markers and impact on survival were evaluated.
Results: Serum BAFF, TACI and BCMA levels were significantly lower in the patient group (p<0.001), while serum APRIL level did not differ significantly between the patient and control groups (p>0.05) (Table 1). Serum BAFF [(p=0,008; r=-0,236)] and BCMA [(p=0,042; r=-0,183)] levels were negatively correlated with Rai stage and serum BAFF level was higher in low-risk patients based on modified Rai staging system (p=0,059). Serum TACI level was higher in CD38 positive patients [(p=0,06; 0,17(0,1-0,86) *vs* 0,13(0,1-1,07)]. Age (p=0,002), Rai stage (p=0,005) and Modified Rai stage (p=0,051) were the significant factors which had an impact on overall survival in multivariate analysis.

Table 1.

	Patient Group	Control Group	p value
BAFF (ng/ml)	0,08(0,05-2,08)	1,46(0,24-2,95)	p<0,001
BCMA (ng/ml)	0,16(0,12-1,93)	1,43(0,87-3,03)	p<0,001
TACI (ng/ml)	0,14(0,1-1,07)	0,28(0,24-0,87)	p<0,001
APRIL (ng/ml)	0,28(0,2-0,65)	0,26(0,24-0,65)	p=0,089

Summary/Conclusions: As BAFF and APRIL display their main biological effects once they bind to their receptors and pass through the intracellular compartment, we consider that it may be more feasible to measure the intracellular levels of these molecules which may be more predictive for B-CLL prognosis. The association of TACI and CD38 expression may indicate the notable balance between proliferation and apoptosis, as CD38 is considered to be a proliferation marker in B-CLL. Further large and prospective studies analyzing the intracellular levels of these molecules are essential to validate the prognostic role of these particular biomarkers in CLL.

PB1797

EXPERIENCE OF IBRUTINIB IN RELAPSED/REFRACTORY B-CELL CHRONIC LYMPHOCYTIC LEUKAEMIA AND MANTLE CELL LYMPHOMA IN A U.K. DISTRICT GENERAL HOSPITAL

J. Lala[1], A. Smith[1,*], C. Millar[1], G. Fellows[1], A. Bryan[1], J. Addada[1]
[1]Haematology, Derby Teaching Hospitals NHS Foundation Trust, Derby, United Kingdom

Background: Constitutive activation of B-cell receptor signalling appears to be essential for the proliferation of malignant B cells. Bruton's tyrosine kinase (BTK) has been identified as an essential component of the B-cell receptor signalling pathway. Ibrutinib is an orally administered BTK inhibitor that antagonises B cell receptor, chemokine & integrin mediated signalling.
Aims: We report our experience of using ibrutinib to treat relapsed/refractory B-cell chronic lymphocytic leukaemia (B-CLL) and mantle cell lymphoma (MCL) in a busy U.K. District General Hospital (DGH) serving a population of 600,000
Methods: 26 patients were commenced on ibrutinib for relapsed/refractory B-CLL or MCL between August 2014 & December 2016. 16 patients had B-CLL and 10 patients had MCL. Patients with B-CLL were commenced on 420mg daily; those with MCL received 540mg daily. The median age at which ibrutinib was commenced was 71.1 years (range 50-85). The median age of patients with B-CLL was 71.1 years (range 50-80) and for MCL was 71.6 years (range 54-85). The median number of prior lines of therapy decreased over the time period from 3.2 in 2014 to 1.2 in 2016. The mean interval between diagnosis and commencement of ibrutinib was 6.7 years (B-CLL) and 4.8 years (MCL). The average number of co-morbidities in both groups was similar: 1.4 in B-CLL and 1.5 in MCL. After May 2015 all patients received aciclovir and co-trimoxazole prophylaxis. Response to ibrutinib was assessed by clinical examination and blood results; imaging and bone marrow examination were conducted at the clinician's discretion.
Results: The median follow up was 15.5 months for B-CLL patients and 8 months for MCL patients. The median survival of all patients who did not receive anti-viral and pneumocystis prophylaxis was 5 months and the median survival for those who did receive prophylaxis was not reached (p <0.0001). The median survival of patients in both groups who had received more than 1 prior line of treatment was 17 months; the median survival in those who had received just one prior line of treatment was not reached (p= 0.0085). In the B-CLL cohort there was no difference in survival between those with and without 17p / p53 deletion. 11/26 patients experienced side effects: 8 had grade 1 and 2 side effects (diarrhoea, drug rash, cardiac arrhythmias) which were easily controlled. 3 patients had grade 4 side effects (1 severe arthropathy, 2 intracranial haemorrhage - one of which was fatal). 4 of the 16 (25%) with B-CLL and 5 of the 10 (50%) with MCL died during the period of follow-up. Causes of death were: intra-cerebral haemorrhage (1), unrelated cancer (1), disease progression (2), disease progression+sepsis (2), sepsis alone (3). Of the remaining 17 patients, 14 continue to receive ibrutinib, 2 (B-CLL) were switched to idelalisib+Rituximab (for grade 4 toxicity) & 1 went on to have an allogeneic transplant (MCL).
Summary/Conclusions: Though our cohort of patients is small, our experience shows that the use of prophylaxis with co-trimoxazole and aciclovir is associated with significantly improved overall survival. Moreover, patients who received fewer lines of prior treatment had a better survival. Patients with 17p/p53 deleted B-CLL responded as well as those without a deletion. Ibrutinib is a very effective therapeutic option in patients with relapsed CLL and MCL.

PB1798

THE VALUE OF RITUXIMAB ADDITION TO CHEMOTHERAPY TREATMENT OF REAL-WORLD CLL PATIENTS: A 15 YEAR SINGLE CENTER EXPERIENCE

L. Van Der Straten[1,*], A.G. Dinmohamed[2,3,4], J.K. Doorduijn[2], P.E. Westerweel[1], A.W. Langerak[5], A.P. Kater [6], M.-D. Levin[1]
[1]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, [2]Haematology, Erasmus MC Cancer Institute, [3]Public Health, Erasmus University Medical Center, Rotterdam, [4]Research, Netherlands Comprehensive Cancer Organization, Utrecht, [5]Immunology, Erasmus Medical Center, Rotterdam, [6]Haematology, Academic Medical Center, Amsterdam, Netherlands

Background: The addition of the monoclonal antibody rituximab to chemotherapy has been shown to improve progression free survival and overall survival in prospective trials in CLL patients. However, CLL patients participating in clinical trials may not be fully representative of the overall patient population in clinical practice as there is selection due to study availability, willingness to participate and various in- and exclusion criteria. To date, the efficacy of rituximab added to standard chemotherapy in first line and relapsed CLL patients has been poorly validated in observational studies in unselected real-world CLL patients.
Aims: To evaluate the efficacy of rituximab-chemotherapy (R-CTX) compared to chemotherapy (CTX) in a real-world CLL population.
Methods: All patients from a large teaching hospital diagnosed with immunophenotypically confirmed CLL in the period from 1-1-2000 up to 1-9-2015 were analyzed for this study and were categorized into two groups (1) those treated with CTX and (2) those who received R-CTX. The clinical outcome of patients was evaluated based on the "treatment-free interval" (TFI), defined as the time from stop of chemo(immuno)therapy to start of next treatment. Patients who did not need next treatment were censored at time of last follow-up or death. In addition, overall survival (OS) for patients treated in the period when rituximab had become available in our center was compared to patients treated before the rituximab era (before and after 1-1-2006, respectively).
Results: A cohort of 375 CLL patients was studied, of whom 124 CLL patients (33%) required treatment in the observation period. The median age at first-line therapy was 67 years; 55% and 45% of these patients received first line CTX or R-CTX, respectively, and 47% of these patients required a second or later line of (R-)CTX. In total 221 treatment periods of (R-)CTX were studied with respect to treatment-free interval, 124 first-line, and 97 courses of retreatment. In the first-line treatment group 12 (10%) and 24 patients (19%) were treated with purine-analogue-based schedules without or with R respectively, *i.e.* (R-)fludarabine or (R-)fludarabine plus cyclophosphamide, 55 (45%) and 31 patients (25%) were treated with chlorambucil/CVP-based regimens without or with R respectively, and two patients (2%) were treated with CHOP and R-bendamustin. The median TFI for patients treated with CTX was 31 months (95%CI; 20 – 42 months) and was significantly better in the R-CTX group where the median TFI was not reached during the observation time (hazard ratio 0.40, 95%CI 0.22 – 0.73). In second or later lines of treatment 15 (15%) and 11 patients (11%) were treated with purine-analogue-based schedules without or with R respectively, *i.e.* (R-)fludarabine or (R-)fludarabine plus cyclophosphamide, 25 (26%) and 31 patients (32%) were treated with chlorambucil/CVP-based regimens without or with R respectively, and 15 patients (15%) were provided with other treatment modalities, *i.e.* (R-)CHOP or (R-)bendamustin. The median TFI for CTX was 27 months (95%CI; 18 – 52 months) *vs* 55 months for R-CTX (95%CI; 41 months – NR), HR 0.47 (95%CI 0.15 – 0.90) for subsequent lines. OS for patients treated in the R era was 48 *vs* 35 months for patients treated before the introduction of rituximab (p=0.02).
Summary/Conclusions: Our study shows that the addition of rituximab improved treatment free interval in first- and subsequent lines and prolonged overall survival in a cohort of CLL patients receiving treatment in routine clinical 'real world' practice.

RICHTER SYNDROME: SERBIAN LYMPHOMA GROUP EXPERIENCE

V. Vukovic[1,*], D. Antic[1,2], N. Milic[3], M. Todorovic-Balint[1,2], J. Bila[1,2], B. Andjelic[1,2], V. Djurasinovic[1,2], A. Sretenovic[1], M. Smiljanic[1], J. Jelicic[1], M. Perunicic-Jovanovic[1], N. Kraguljac-Kurtovic[1], P. Djurdjevic[4,5], Z. Cvetkovic[2,6], A. Zivanovic[7], B. Mihaljevic[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Medical Faculty, [3]Institute for Medical Statistics and Informatics, Medical Faculty, University of Belgrade, Belgrade, [4]Medical Faculty, University of Kragujevac, [5]Clinic for Hematology, Clinical Center Kragujevac, Kragujevac, [6]Clinic of Internal Medicine, Clinical Hospital Center Zemun, [7]Clinic of Hematology, Medical Military Academy, Belgrade, Serbia

Background: Richter syndrome (RS) represents transformation of chronic lymphocytic leukemia/ small lymphocytic lymphoma (CLL/SLL) into more aggressive B-cell lymphoproliferative disorder, most commonly, diffuse large B cell lymphoma (DLBCL). vera rarely classical Hodgkin lymphoma (HL). In some point of disease course, 2-10% of all CLL/SLL population develope RS, usually exhibiting chemoresistance and survival within a year after diagnosis.
Aims: The aim of the study is to evaluate clinical, laboratory and histopathological features of patients with RS at transformation, and their impact on the outcome.
Methods: We processed data from the medical records of 36 CLL and SLL patients with RS diagnosed and treated in four institutions in Serbia from 2003 to 2016: Clinic for Hematology, Clinical Center of Serbia; Clinic for Hematology, Medical Military Academy; Clinical Hospital Center Zemun; and Clinic for Hematology, Clinical Center Kragujevac. In all of RS patients, diagnosis was established after histopathological and immunohistochemistry analysis of biopted tissue (lymph node, bone marrow, Waldeyer's ring, maxillary sinus, spleen or liver).
Results: In four institutions RS was diagnosed in 36/1250 CLL/SLL patients (2.8%). Median age was 57.5 years (range 41-79). In 16 (44%) patients RS was confirmed in lymph node sample, in 13 (35%) patients in bone marrow, in 4 (11%) patients in Waldeyer´s ring, in 2 (5%) patients in maxillary sinus, in 2 (5%) patients in liver or/and spleen, while in 3 patients in more than one location. Histopathological findings of all patients in transformation were consistent with DLBCL, except one, showing pattern of HL. Prior to the transformation, 26 (72%) patients received chemotherapy (Chlorambucil 6 patients, Fludarabin based regimens 11 patients, CHOP 3 patients, COP/RCOP 4 patients, other modality 3 patients), 4 (11%) of them were on the "watch and wait" strategy, while 6 (17%) patients were diagnosed with RS at presentation, and treated as RS. Median time to transformation was 36 (0-180) months, At the time of transformation median LDH and beta-2 microglobulin levels were significantly higher than on presentation (p=0.035 and p=0.010, respectively). The majority of patients received CHOP (20/36, 55%) and RCHOP (7/36, 19%) as initial therapy for RS. The reminder of patients received other treatment modalities, such as ESHAP, FC, high dose corticosteroids, COP, RCOP and radiotherapy. After excluding 6 patients with SLL from the group, Cox regression analysis showed that high LDH and low Hb levels at the time of transformation are significant predictors of shorter survival after diagnosis of RS (HR=1.001; 95% CI 1.000-1.001; p<0.001 and HR=0.978; 95% CI 0.961-0.995; p=0.011, respectively). Bone marrow as a site of transformation did not reach statistical significance as a predictor of shorter survival after transformation (p=0.087). Median survival after diagnosis of RS was 8 months (range 0-133) (Figure 1).

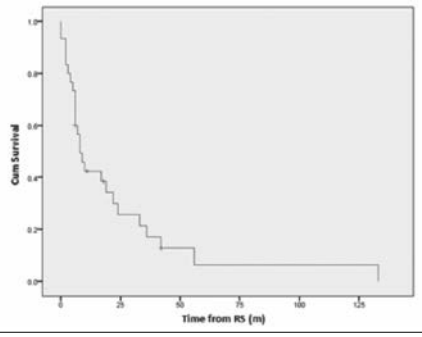

Figure 1.

Summary/Conclusions: Incidence of RS in our study is partly coherent with literature data. Levels of LDH and Hb at the time of transformation are significant predictors of outcome of patients with RS. Real number of patients with RS is probably higher, but commonly bad condition of these patients on diagnosis of RS probably influences the decision of a clinician not to indicate biopsy.

INFECTIOUS COMPLICATIONS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA TREATED WITH IBRUTINIB

E. Wąsik-Szczepanek[1,*], A. Szymczyk[1], O. Czabak[1], M. Cioch[1], M. Wach[1], M. Podhorecka[1], B. Sokołowska[1], M. Pasiarski[2], J. Kozińska[1], I. Hus[1], D. Szczepanek[3], K. Kotwica[1], A. Szczepanek[1], M. Hus[1]
[1]Haematooncology and Bone Marrow Transplantation, Medical University in Lublin, Lublin, [2]Haematooncology, Medical University in Kielce, Kielce, [3]Neurosurgury, Medical University in Lublin, Lublin, Poland

Background: Chronic lymphocytic leukaemia (CLL) is characterised by frequent co-existent infectious complications. They stem from, among other things, hypogammaglobulinemia, which is connected with CLL, and correlates with the disease duration and severity, as well as T-lymphocyte function disorders. The application of innovative therapies (chemoimmunotherapy) on the one hand facilitates considerable improvements in treatment outcomes and on the other hand it increases the risk of life-threatening infectious complications. The introduction of a new drug, ibrutinib (Bruton's kinase inhibitor), has created a unique opportunity for CLL patients, especially those with prognostically unfavourable genetic aberrations (del17p), or in the case of whom previous chemotherapies have failed to give satisfying results. Previous observations indicate the risk of side effects (*e.g.* bleeding, infectious complications, heart rhythm disorders) which might sometimes limit the applicability of ibrutinib in some CLL patients.
Aims: The aim of this paper was to evaluate the risk of infectious complications in persons with CLL, and to determine potential correlations between possible infectious complications and selected clinical, morphological and biochemical parameters.
Methods: The study comprised 43 CLL patients aged 48-82 years (average age 67 years), 18 women and 25 men. At the beginning of the ibrutinib therapy the patient's disease was at the 2-4 clinical stage, according to Rai *et al.* Usually they were individuals who had received a couple of previous chemotherapies (from 1 to 7) which contained, inter alia, purine analogues, and the monoclonal antibodies (rituximab, alemtuzumab, ofatumumab). Ibrutinib was administered at a dose of 420 mg/d.
Results: Infectious complications were observed in 16 patients (37.2%). These included, for example, upper respiratory tract infection, bronchitis, pneumonia, urinary-tract infections, pharyngitis. The conducted analysis showed a statistically significant correlation between the concentration of IgM in the blood serum (before ibrutinib administration) and infectious complications during these therapy ($p<0.05$). The average IgM concentration in patients with complications was considerably lower when compared to people who did not experience any complications. The patients (n=3; 6,98%) with complications at the moment of the CLL diagnosis also had them during the ibrutinib treatment. This phenomenon was confirmed in 13 patients (33%) in the other group. The correlation was borderline significant ($p=0.09$). Infectious complications were observed more frequently in the patients with 3-4 stage CLL (according to Rai *et al.*) than in the individuals at the less-advanced clinical stages of the disease (0-2), and this correlation also showed borderline significance ($p=0.08$). No significant correlation was detected between the risk of infectious complications and earlier therapy with purine analogues and neutropenic episodes during the ibrutinib therapy.
Summary/Conclusions: Ibrutinib is considered to be a real breakthrough in CLL treatment; but it has to be borne in mind that the drug gives possible side effects which might occur during therapy. They include infectious complications which are among the main causes of death in this group of patients. The results obtained by us indicate that the risk of infection during ibrutinib therapy relates mainly to patients with low IgM concentration in the blood serum and at more advanced clinical stages of the disease. In this case the occurrence of previous complications (before ibrutinib administration) is also relevant. We are aware of the limitations of our work related to the small number of patients. Yet, even at this stage, it is possible to select CLL patients with increased risk of such usually life-threatening complications.

PB1801

MONOCLONAL B-CELL LYMPHOCYTOSIS AND PROSTATE CANCER: AN UNEXPECTED, POSSIBLE ASSOCIATION

F. D'Auria[1,*], L. Rago[1], L. Valvano[1], T. Statuto[1], A. Traficante[1], V. Simeon[1], V. Fusco[1], P. Musto[1]
[1]IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture (PZ), Italy

Background: Monoclonal B-cell lymphocytosis (MBL) is a recently recognized entity characterized by the presence, in the peripheral blood, of a monoclonal B-cell population lower than 5000/µl, in the absence of any type of clinical features. MBL clones may have: a) chronic lymphocytic leukemia (CLL-like) phenotype (CD5+, CD19+, CD23+, CD20 dim); b) atypical CLL phenotype (CD5+, CD19+, CD23- or CD20 bright); c) non-CLL phenotype (CD5-). MBL can be also distinguished in "low-count" (<500/µl) and "high-count" (>500/µl) subtypes. High-count MBL frequently shows typical CLL phenotypic/genetic features and require adequate follow-up in order to detect their possible evolution into symptomatic CLL. MBL showing a clonal B-cell count higher than 1000-1500/µl are usually defined "clinical" MBL. Using highly sensitive (*i.e.* >6 colors and >500000 events) flow cytometry approaches, CLL-like MBL clones have been found at a frequency of 7-12% in healthy subjects, showing, however, very low median counts of clonal B-cell (10-170/µl), with only 0,14% being clinical MBL. Though several studies have described the association between CLL and various types of neoplastic disorders, only few data exist about the risk of non-hematologic cancer in individuals with MBL; in particular, no association between MBL and prostate cancer (PC) has been so far reported.
Aims: To study prospectively the frequency of CLL-like MBL clones in patients affected by PC compared to healthy males of the same ages, after our previous occasional observation of an apparently increased MBL incidence at baseline in a cohort of patients with PC originally studied to detect lymphocyte abnormalities possibly induced by radiotherapy (RT).
Methods: We enrolled 34 consecutive patients affected by PC (mean age 74 years, range 58-91), naïve for chemotherapy (sixteen previously treated with hormone-therapy). All patients were planned to receive whole-pelvis RT with radical (n. 23) or salvage (n. 11) intent. Fifty-four healthy males (mean age 71 years, range 58-87) represented the control group. Immunophenotypic analysis of peripheral lymphocytes before RT was performed by BD FacsCanto II flow cytometer, using a 5-6 colors approach and the following antibody combinations: CD19 FITC/CD5 PE/CD45 PerCP/CD20 PE-Cy7/CD23 APC; Kappa FITC/Lambda PE/CD19 PerCP-Cy5.5/CD20 PE-Cy7/CD5 APC/CD45 APC-Cy7. For each sample, 100000 events were collected. CD45+ lymphocytes were gated on CD45 *vs* SSC dot plot, then B cells were isolated by gating on CD19 and CD19+ CD5+ cells were interrogated for intensity of CD20. Finally, CD19+ CD5+ CD20dim selected population was analyzed for light chain clonality and CD23 expression.
Results: Median (range) absolute counts of white blood cells (WBC), total lymphocytes and B-cells, as well as absolute single values of MBL clones are reported in Table 1. In PC patients we found 3 MBL (8,8%), two of which were "high count/clinical" MBL (5.8%). In contrast, in healthy subject group, only one "low count" MBL (1.8%) was detected, showing a very small clone (8 cells/µl). Such a difference was not statistically significant ($p=0.2$).

Table 1.

	Median WBC/µl (range)	Median Lymphocytes/µl (range)	Median B-cells/µl (range)	MBL n. (%)	Absolute MBL clone values/µl
Prostate cancer (n. 34)	7404 (5100-12900)	2304 (1200-4900)	264 (52-1984)	3 (8.8%)	294, 1254, 1970
Controls (n. 54)	7577 (4090-12380)	2237 (800-5100)	201 (28-484)	1 (1.8%)	8

Summary/Conclusions: The preliminary results of our prospective study, performed using a routine, not highly sensitive flow cytometry approach, highlight a possible association between (clinical?) MBL and PC, never described before and probably warranting further investigation in a larger number of patients.

Chronic myeloid leukemia - Biology

IDENTIFICATION OF NOVEL MUTATIONS IN CANCER-RELATED GENES IN HUMAN ERYTHROLEUKEMIA K562 CELL LINE BY NEXT-GENERATION SEQUENCING

M. Pepek[1,2,*], M. Kurkowiak[1], M.M. Machnicki[1,2], I. Solarska[3], K. Borg[3], M. Rydzanicz[4], P. Stawinski[4], R. Ploski[4], T. Stoklosa[1]
[1]Department of Immunology, Medical University of Warsaw, [2]Postgraduate School of Molecular Medicine, [3]Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, [4]Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland

Background: Chronic myeloid leukemia (CML) is a clonal hematopoietic stem cell disorder characterized by reciprocal chromosomal translocation t(9;22)(q34;q11), resulting in the formation of the *BCR-ABL1* fusion oncogene. One of the most common CML *in vitro* model is the K562 BCR-ABL1-positive human erythroleukemia cell line derived from a female patient with CML in blastic phase (CML-BP) and representing an important tool for the studies of malignant hematopoiesis in last decades. Although K562 karyotype was described several times, detailed genomic analysis of this cell line is not yet available and to our best knowledge there are no publications yet describing complex genomic landscape of K562 cells.
Aims: The aim of our study was to determine the mutational landscape of K562 cell line using next-generation sequencing (NGS). Additionally classical fluorescence *in situ* hybridization (FISH) with BCR and ABL1 probes was performed to confirm cytogenetics.
Methods: The K562 cell line was purchased from DSMZ (Braunschweig, Germany). We analyzed almost 1300 genes implicated in human cancer using custom designed capture (SeqCap EZ, NimbleGen, Roche) followed by high-throughput sequencing on Illumina HiSeq 1500. Common variants (>1%) gathered in ESP6500 and 1000 genomes projects and our internal exome database were filtered out and the subsequent analysis was focused on putative protein damaging variants with the frequency in the database from NHLBI GO exome sequencing project less or equal to 0.01. We used different bioinformatic tools for variant effect prediction (eg. PolyPhen-2, SIFT, IntOGen). Mutations were confirmed with Sanger sequencing. FISH was performed using commercially available probes (Vysis, Abbott, USA), that identifies *BCR-ABL1*/*ABL1-BCR* fusion genes.
Results: Sequencing and bioinformatical analysis revealed 88 variants with potential biological significance. We detected Q136fs*13 mutation in *TP53,* which has already been described in K562 cell line previously by ATCC, but we have also identified several new mutations in genes involved in tumorigenesis and drug resistance (Table 1). Moreover, cytogenetic analysis showed both multiplication of the *BCR* and *ABL1* genes and amplification of the *BCR-ABL1* fusion gene (Ph chromosome is present in at least four additional copies).

Table 1. Selected prominent mutations identified in K562 cells.

Mutation	NCBI Reference
TP53 p.*Q136fs*13 (known)*	NM_001126114.2

AKT3 p.G37*	NM_001206729.1
BRCA1 p.I540V	NM_007297.3

Summary/Conclusions: We describe several new mutations in such genes as *ASXL1*, *BRCA1* or *MLH1* in one of the most frequently used cell line in leukemia research, K562 erythroleukemia. Our results confirm high level of genomic instability in the blastic phase of CML represented by the K562 cell line and add new, valuable information for researchers who want to employ this cell line. The awareness of the genomic aberrations present in the K562 erythroleukemia cell line is essential for further studies as those aberrations may have a significant impact on the observed results.

PB1803

INVESTIGATION OF POLYMORPHISMS RELATED TO MIR-608 IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

N. Ryabchikova[1], G. Safuanova[1,*], I. Minniakhmetov[2], A. Sultanbaev[1], E. Khusnutdinova[2]
[1]Bashkir State Medical University, [2]IBG USC RAS, UFA, Russian Federation

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disorder characterized by the expression of the BCR-ABL oncoprotein, which is essential for the pathogenesis of the disease. Imatinib, an ATP-competitive selective inhibitor of BCR-ABL, has unprecedented efficacy for the treatment of CML. Several cellular and genetic mechanisms of imatinib resistance have been proposed, including overexpression of the BCR-ABL gene, the tyrosine kinase domain mutations, pharmacokinetic and pharmacodynamic factors.
Aims: The purpose of this study was to investigate miRNA-608 role in response to therapy with tyrosine kinase inhibitors (Imatinib). In this study, we analyzed rs9762 SNP located in a miRNA-608 binding site of 3′UTR of BCR-ABL gene and rs4919510 SNP in the mature sequence of miR-608 in CML patients with different response to tyrosine kinase inhibitor therapy. These polymorphisms disrupt the negative effect of mir-608 on its target BCR-ABL.
Methods: In our study 76 CML patients at the age of 15−65 were involved. Genomic DNA was extracted from peripheral blood leukocytes by standard phenol-chloroform method. Genotyping was performed by the PCR-RFLP technique.
Results: Combination of genotypes affecting mir-608/BCR-ABL1 interaction (*GG in mir-608 binding site and/or *GG in mature miRNA itself) was revealed with 81% in CML patients with uneffective therapy. We suggest that mir-608 could possess oncosuppressing activity as mir-203 but it should be confirmed by further experiments.
Summary/Conclusions: miRNAs could be a perspective tool for therapy and polymorphisms affecting its regulation should also be considered.

PB1804

TARGETED STRATEGY FOR ABL TYROSINE KINASE INHIBITOR RESISTANT PHILADELPHIA CHROMOSOME POSITIVE LEUKEMIA CELLS

S. Okabe[1,*], T. Tauchi[1], Y. Tanaka[1], K. Ohyashiki [1]
[1]Department of Hematology, TOKYO MEDICAL UNIVERSITY, Shinjuku-Ku, Japan

Background: Although ABL tyrosine kinase inhibitors (TKIs) such as imatinib have demonstrated the potency against Philadelphia chromosome (Ph)-positive leukemia patients, resistance to ABL TKI can develop in chronic myeloid leukemia (CML) patients. Therefore, new approach against ABL TKI resistant cells may improve the outcome of Ph-positive leukemia patients. It has already reported that ABL kinase domain mutations have been implicated in the pathogenesis of ABL TKI resistance, however, it is fully not known the molecular mechanism of drug resistance including second (nilotinib and dasatinib) and third generation (ponatinib) ABL TKIs.
Aims: As leukemia is a genetic disease driven by heritable or somatic mutations, we hypothesized that ABL TKI resistance may often happen due to additional somatic mutations in the oncogene.
Methods: We established several TKI-resistant *in vitro* cell line models. We also investigated model to evaluate the next-generation sequencing (NGS) panel, NGS platform to screen mutational hotspots in 50 leukemia-related genes.
Results: We established ABL TKI resistant cell lines (K562 imatinib-R, K562 nilotinib-R, K562 dasatinib-R, K562 ponatinib-R, Ba/F3 T315I and Ba/F3 ponatinib-R) in this study. We conducted fluorescence *in situ* hybridization (FISH) analysis on parental K562 and ABL TKI resistant K562 cells. BCR-ABL expression levels were not increased in ABL TKI resistant K562 cells compared to parental K562. We next investigated the BCR-ABL point mutation by direct sequence analysis. We could not detect the BCR-ABL point mutation in ABL TKI resistant K562 cells. However, the exon 4 deletion in the BCR-ABL gene was found in K562 ponatinib-R cells. In contrast, compound mutations in BCR-ABL were found in Ba/F3 ponatinib-R cells. K562 ponatinib-R cells were also highly resistant to imatinib, nilotinib and dasatinib. We examined the intracellular signaling of ABL TKI resistant K562 cells. Phosphorylation of BCR-ABL and Crk-L was reduced in K562 dasatinib-R cells, however, MAPK activity was increased. In K562 ponatinib-R cells, MAPK activity was reduced. We next evaluated the NGS panel (GeneRead DNAseq Targeted Panels V2) to investigate the mutation. We found that several somatic mutations in TET2, FLT3, RB1, TP53, SETBP1, ASXL1, and BCORL1 in parental K562 cells. We also found that additional somatic mutations in K562 imatinib-R (IDH1 and KRAS), K562 dasatinib-R (IDH1) and K562 ponatinib-R (SF3A1). We could not detect additional mutation in K562 nilotinib-R cells. We next investigated the MEK inhibitor and IDH1 inhibitor activity against K562 imatinib-R and K562 dasatinib-R cells. MEK inhibitor or IDH1 inhibitor did not induce cell growth inhibition directly. However, combined treatment of ABL TKI resistant K562 with imatinib or dasatinib and MEK inhibitor or IDH1 inhibitor caused more cytotoxicity than each drug alone. Because aberrant activation of PI3K signaling pathway and deregulation of HDAC activity may be a cause of malignant disease in humans, we examined the PI3K and HDAC inhibitor in ABL TKI resistant cells. We found 72 h treatment of oral inhibitor of class I PI3K as well as class I and II HDAC enzymes, CUDC-907 exhibits cell growth inhibition ABL TKI resistant K562 cells and Ba/F3 ponatinib-R cells in a dose dependent manner. In the mouse study, a dose of 20 mg/kg/day p.o of ponatinib and 30 mg/kg/day p.o of CUDC-907 inhibited tumor growth of T315I mutant cells compared with control mice and induced apoptosis in tumor samples.
Summary/Conclusions: Our study indicated that leukemia cells have acquired resistance through somatic mutation or exon 4 deletion in the BCR-ABL gene, suggested that individual based investigations may be important to evaluate the ABL TKI resistance. We also provide the promising clinical relevance as a candidate drug for treatment of ABL TKI resistant leukemia patients.

PB1805

FLUORESCENCE *IN SITU* HYBRIDIZATION SIGNAL PATTERNS AND INTRACHROMOSOMAL BCR-ABL1 AMPLIFICATION ANALYSIS IN IMATINIB-RESISTANT CHRONIC MYELOGENOUS LEUKEMIA PATIENTS USING TRICOLOR DUAL FUSION PROBE

K. Bommannan[1,*], S. Naseem[1], N. Varma, P. Malhotra[2], J. Binota[1], S. Varma[2]
[1]Hematology, [2]Internal Medicine, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Conventional cytogenetics is a common modality for tyrosine kinase inhibitor (TKI) response assessment in chronic myelogenous leukemia (CML) patients. There is no consensus regarding the use of conventional bone marrow (BM) cytogenetics or peripheral blood (PB) interphase fluorescence *in situ* hybridization (I-FISH) during follow-up. The routine dual colour FISH probes are less sensitive to reliably identify der(9) deletions during follow-up. BCR/ABL/ASS1 tri-colour dual fusion (TCDF) probe is highly sensitive and specific in identifying der(9) deletions.
Aims: Our aim was to identify the I-FISH fusion patterns of BCR/ABL/ASS1 TCDF probe and correlate the patterns with patient-specific molecular genetic parameters.
Methods: This was an ethically approved study conducted at a government-funded tertiary care institute. From January 2015 to June 2016, PB I-FISH analysis was performed on European LeukemiaNet defined imatinib-resistant CML patients using BCR/ABL/ASS1 TCDF probe (Abbott Laboratories, Abbott Park, Illinois, USA). The residual *BCR-ABL1* transcript load was monitored in international scale (*BCR-ABL1*^{IS}) using an automated cartridge-based GeneXpert system (Cepheid, Sunnyvale, CA, USA).
Results: On analyzing 37 adult patients, all had residual Philadelphia (Ph) chromosomes (100%). Classic Ph fusion pattern was seen in 33 (89%), derivative chromosome 9 [der(9)] deletions in 25 (67.5%) and supernumerary Ph chromosomes in 11 (30%) patients. Coexistence of classical fusion and der(9) deletions were seen in 21 patients (57%), whereas 8 patients (22%) had a mutual existence of classical fusion, der(9) deletions and supernumerary Ph chromosomes. None had Ph amplification. Figure 1 demonstrates the I-FISH patterns seen in a 43-year-old male diagnosed with CML-CP and had progressed to blast crisis at his 72nd month of imatinib therapy. In this Figure red, yellow and white arrows indicate blast cells without Ph chromosome, Ph+ blast with a loss of residual *ABL1* on der(9)classical and random signal overlap, respectively. A mean (± S.D) of 29% (± 30) and 18% (± 17) der(9) deleted cells were seen amongst patients with b2a2 and b3a2 *BCR-ABL1* transcript types, respectively and this difference was statistically significant (p=0.008). There was also a significant difference in the disease transformation status according to the percentage of der(9) deleted cells (p=0.03). In this regard, patients with progressive disease (accelerated phase/ blast crisis progression) had a mean (± S.D) of 47% (± 35) der(9) deleted cells in comparison to 19% (± 20) such cells in patients without disease transformation. In addition, patients with Ph duplication/triplication had a mean (± S.D) *BCR-ABL1*^{IS} levels of 49.478% (± 40.184), in comparison to *BCR-ABL1*^{IS} levels of 16.00% (± 19.993) in patients without these anomalies and this difference was also statistically significant (p=0.029).

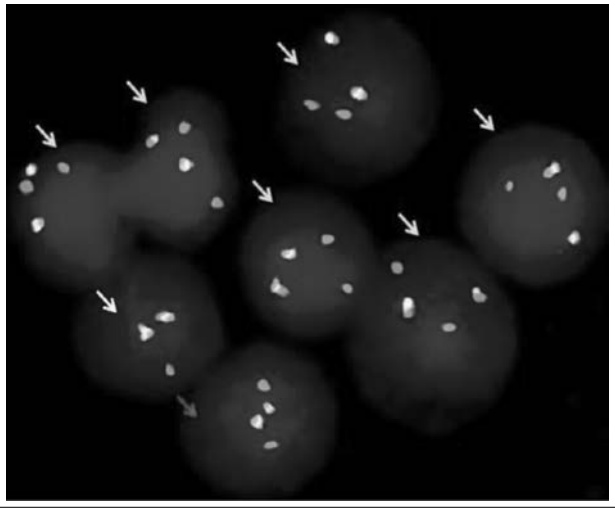

Figure 1.

Summary/Conclusions: Our work would be an appropriate reference material for I-FISH signal interpretation using BCR/ABL/ASS1 TCDF probe. We have demonstrated a high frequency of der(9) deletions, clonal heterogeneity and absence of *BCR-ABL1* amplification in an imatinib-resistant Indian CML cohort. For the first time, a significant association of der(9) deleted cell percentage with b2a2 transcript type and disease transformation status has been identified and the same has to be tested in a larger cohort.

PB1806

ARE YOU ACTUALLY SUSPECTING A CHRONIC MYELOID LEUKEMIA WHEN ORDERING A BCR/ABL RT-PCR?

L. Abalo Perez[1,*], C. Guillén Rienda[1], M. Sopeña Corvinos[1], W.M. Torres Jimenez[1], R. Guillén Santos[2], J. Villarrubia[1], F.A. Gonzalez Fernandez[1], F. Cava Valenciano[2]
[1]Hematology Department, [2]Head of the Laboratory, Central Laboratory BRSalud Madrid. Infanta Sofía Hospital, Madrid, Spain

Background: Chronic myeloid leukaemia (CML) is a myeloproliferative neoplasm (MPN). It is characterized by a reciprocal t(9:22)(q34;q11.2) resulting in the fusion oncogene *BCR/ABL* in a hemopoietic stem cell. Clinical features are absent in nearly 20-40% of patients at diagnosis time. Hence, laboratory suspicion is crucial. Peripheral blood shows leukocitosis with left shift and "myelocyte bulge", absolute eosinophilia, and absolute basophilia invariably present[1-3]. The demonstration of the Philadelphia (Ph) chromosome with cytogenetic analysis, or *BCR/ABL* fusion gene by qRT-PCR will confirm the diagnosis (typical CML).
Aims: In order to gain accuracy when *BCR/ABL* PCR is ordered, we review myeloproliferative hematimetric parameters, with special focus in basophilia, before performing molecular analysis.
Methods: We retrospectively reviewed 299 *BCR-ABL* PCR requests received at our laboratory between January 1, 2015 and January 1, 2017. 80% of the total requests were ordered by haematologists physicians, 13.46% by other medical specialities (11.5% internal medicine) and 7.7% from the laboratory. Complete blood cell count (CBC) were analysed by ADVIA 2120. Neutrophilia was defined in our laboratory as absolute neutrophil count of >7.7x10 9/L, and basophilia was defined as absolute basophil count of >0.2 x10 9/L. A total of 299 requests for PCR of *BCR-ABL* were reviewed by laboratory hematology staff, before performing them, according to 2008 WHO Classification of Hematologic neoplasms criteria. We reviewed clinical history, previous CBC and PBM if necessary for this screening. We performed 235 test (78.6%) and 64(21.4%) were considered inadequate according former criteria. qRT-PCR p210 was performed and if a negative result was obtained with high CML suspicion qRT-PCRp190 and qRT-PCRp230, such as cytogenetic studies were performed.The statistical analysis was performed with STATA.
Results: 235 *BCR/ABL* by PCR tests were performed and 24 (10.21%) resulted positive. 167 (71.06%) were placed for neutrophilia; 41 (17.87%) for thrombocytosis and 26 (11.07%) for other criteria (eosinophilia, monocytosis, splenomegaly or combined).Among 24 positive cases 100% presented basophilia at diagnostic time and 91.66% (22/24) presented basophilia and neutrophilia. Two cases without neutrophilia at diagnosis were CML with extreme trombocytosis. We found 33 cases with basophilia among 235 patients. 24 cases (72.73%) were diagnosed of CML and 9(27.27%) resulted in other MPN Ph- or unclassifiable MPS/MDS neoplasm. Our results show that when CML is suspected, basophilia>0.3 x10 9/L has a 100% sensitivity and 95.75% specificity. ROC curve for basophilia as a screening test before performing *BCR/ABL* PCR is 0.984 (Figure 1).

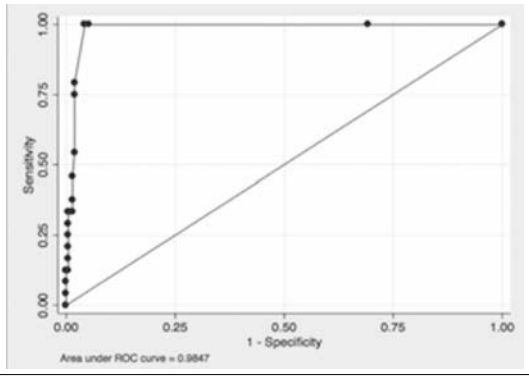

Figure 1.

Summary/Conclusions: Our results show that basophilia should be carefully investigate when CML is suspected, with high sensibility (100%) and specificity (95.75%). In cases no CML with basophilia >0.3 x10 9/L, further investigation should be performed in order to diagnose a MPN Ph- or MDS/MPN.Even basophilia is well stablished as nearly universal in CML [1,3,4], this study reveals it is not always pursue enough, when clinicians ask for a molecular study.

PB1807

BCR-ABL DEL. C.1086-1270 (P.R362FS*21) AND TKI RESISTANCE IN CML PATIENTS FROM RUSSIAN FEDERATION

A. Abdullaev[1,*], I. Mikhailov[2], O. Nesterova[2], A. Odilov[3], T. Makarik[1], E. Stepanova[1], S. Treglazova[1], A. Sudarikov[1]
[1]Molecular hematology, National Research Center for Hematology, [2]Faculty

of fundamental medicine, Lomonossov Moscow State University, Moscow, Russian Federation, [3]Medical faculty, Tashkent Medical Academy, Tashkent, Uzbekistan

Background: Data concerning the impact of BCR-ABL del. c.1086-1270 on TKI resistance in CML is still controversial. This mutation was first described by Curvo *et al.* (2008) and was thought to confer TKI resistance. However computer modeling performed by Meggyesi N. *et al.* (2012) revealed disruption of ATP binding site in mutated tyrosine kinase therefore abrogating enzymatic activity. Nevertheless pathogenic effect of BCR-ABL p.R362fs*21 could be attributed to the formation of heterodimer with "wild type" Bcr-Abl p210 as described by Poulikakos P.I. *et al.* (2011).
Aims: To assess the impact of BCR-ABL del. c.1086-1270 (p.R362fs*21) on TKI resistance in CML patients from Russian Federation.
Methods: 33 male and 49 female CML patients (age 24-80) with BCR-ABL transcript level >0.1% were included in the study. BCR-ABL del. c.1086-1270 was estimated by nested PCR followed by Sanger sequencing. Initial screening for deletions was performed by means of fragment analysis (Applied Biosystems 3130).
Results: 92 RNA (cDNA) samples isolated from peripheral blood of 82 CML patients were tested. BCR-ABL del. c.1086-1270 (p.R362fs*21) was found in 32 patients (39%). 15 out of 32 (47%) patients with deletion were TKI sensitive while 17 (55%) were TKI resistant. In one TKI resistant case BCR-ABL del. c.1086-1270 was accompanied by BCR-ABL c.844G>C p.E282Q point mutation not described so far (Figure 1). This mutation was found in BCR-ABL del. c.1086-1270 transcript only and was absent in "wild type" Bcr-Abl p210 transcript amplified from the same patient.

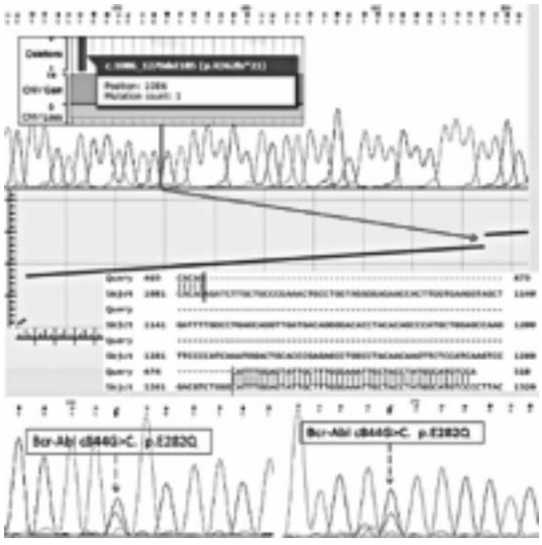

Figure 1.

Summary/Conclusions: BCR-ABL del. c.1086-1270 could be found in almost half of CML patients and have no evident impact on the induction of big molecular response in TKI sensitive cases. Our observation that independent c.844G>C p.E282Q point mutation expressed on the same BCR-ABL transcript with deletion c.1086-1270 (p.R362fs*21) being absent in "wild type" transcript strongly contradicts the hypothesis, that del. c.1086-1270 could be generated by alternative splicing of "wild type" BCR-ABL transcript.

PB1808

PEROXIREDOXIN II ACTIVITY HAS IMPORTANT ROLES TO CONTROL ABL TYROSINE KINASE ACTIVITY IN STIS TREATED CML PATIENTS AND ITS POTENTIAL APPLICATION IN IMATINIB RESISTANCE

E.S. Yoo[1,*], Y.-C. Mun[1], J.-Y. Ahn[1], J.-W. Huh[1], C.-M. Seong[1]
[1]Ewha Womans University MokDong Hospital, Seoul, Korea, Republic Of

Background: Therapies targeting the redox environment such as over-expression of antioxidants or antioxidant treatment, could inhibit tumor cell growth even resistant cells. Bcr-Abl oncogene is known to induce high levels of intracellular ROS which may further induce genomic instability with malignant transformation and even imatinib (IM) resistance. Variable expression of antioxidants enzymes in leukemia, with limited studies with variable results so far. Altered redox biology in leukemia also has implications for therapeutics.
Aims: We investigated the roles of PRX II in CML primary cells at diagnosis and remission during signal transduction inhibitor (STIs), and tested the same roles in Ph+ cell lines.
Methods: Three BCR-ABL1 positive cell lines with different resistance to TKI and generating IM-resistant K562 cells by chronic exposure of increasing concentrations of IM were compared with cell growth by MTT assay, BCR/ABL expression by western blot analysis, changes of intracellular ROS level and antioxidant enzymes such as peroxiredoxin (Prx) 1, 2, 3 using immunoblot assay according to different concentrations of IM between 0 to 10 μM in time dependent manner (24 hours/48 hours). We also repeatedly investigated the effects of IM therapy using PRXII overexpressed K562 cells by transfection.
Results: Three BCR-ABL1 positive cell lines showed significant change in cell viability, Intracellular ROS level, eradication of BCR/ABL oncogene and levels of Prx2 during IM treatment with different response each other in degree and pattern by IM exposure. The levels of BCR-ABL1 oncogene were slightly decreased in Prx2 overexpressed K562 cells. Moreover, Prx2 overexpressed K562 cells showed further down-regulation of Bcr-Abl oncoprotein by IM treatment.
Summary/Conclusions: Our findings may contributes to find a new pathway on which TKIs are working besides the mechanisms of ATP binding competitively, blocking the binding of ABL-BCR kinase and substract resulting apoptosis of Ph+ cells. In addition develop the new strategies to overcome the situation of the Imatinib resistance in P210 BCR-ABL positive disease in the future. The importance of the roles of ROS and its PRX II, antioxidant enzymes in CML is further established by our work.

PB1809

FUNCTIONAL CHARACTERISTICS OF ERYTHROID PROGENITOR CELLS OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB AND NILOTINIB

T. Perekhrestenko[1,*], I. Sviezhentseva[2], D. Bilko[2], N. Tretiiak[1], I. Dyagil[3]
[1]blood disease, State Institution «Institute of Hematology and Transfusiology of NAMS of Ukraine», [2]center of molecular and cell research, University of kyiv Mogyla Academy, [3]department of hematology and transplantology, State institution "National Research Center of Radiation Medicine, Kyiv, Ukraine

Background: It is believed that chronic myeloid leukemia arises as a result of myeloid progenitor cell malignancy. There are changing of proliferative activity in granulocyte-macrophage and erythroid hematopoiesis germs in patients bone marrow. Currently we don't have definitive results regarding tyrosine kinase inhibitors influence on erythropoietic cell characteristics of patients with CML.
Aims: the aim of study was to determine functional characteristics of erythroid progenitor cells of patients with chronic leukemia treated with Imatinib and Nilotinib.
Methods: We studied 300 bone marrow samples from 75 patients: with initial diagnosis of CML (n=7), patients receiving drug imatinib (n=47) and patients who taking nilotinib (n=21). We provide studying of erythroid mononuclears in semisolid *in vitro* and *in vivo* cultures. For *in vivo* culture we used special gel capsule, allowing cytokines and growth factors of mouse body affect human mononuclear cells. For *in vitro* culture we added 20% fetal calf serum, 30 ng/ml erythropoietin, and 20 ng/ml mlinterleykin-6 and interleukin-9. Cultivation was provided 14 days, then counted the number of erythroid colonies and provided their morphological studies.
Results: The results showed that the increase of erythroid progenitor cells proliferation rates and the reduction of differentiation rates as a result of the parallel cultivation of patients' bone marrow cells *in vivo* and *in vitro* happen irrespective of the presence of cytokines and growth factors in a normal microenvironment of these cultures. In addition, we showed that bone marrow cells of CML patients form erythroid colonies, when placed in the animals' body without previous anemia. Moreover, correlative relationship was found between the number of erythroid colonies and the number of leukemic cells in the patients bone marrow. It was established that the acquisition of leukemic clone cells resistance to TKI is characterized by increased proliferative activity irrespective of soluble microenvironment factors as well as the culture medium in the erythropoietin presence.
Summary/Conclusions: The normal microenvironment factors not effect on the erythroid progenitor cell proliferation independence of the response to TKI therapy. This may explain the fact that we don't have an increase the number of erythroid cells in patient bone marrow compared to culture *in vitro.* In addition, the ability of erythroid progenitor cells to form colonies in the absence of erythropoietin in culture can serve as an additional prognostic factor in the formation of resistance to TKI.

PB1810

DEVELOPMENT OF FRAGMENT ANALYSIS MULTIPLEX-PCR METHOD TO DETECT TRANSCRIPTS OF BCR-ABL FUSION GENE IN CHRONIC MYELOID LEUKEMIA

L. Reguilón-Gallego[1,*], F. Ferrer-Marín[1], R. Cifuentes[1], V. Vicente[1], R. Teruel-Montoya[1]
[1]Hematología y Oncología Médica, Hospital Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII) , Murcia, Spain

Background: Chronic myeloid leukemia (CML) is a myeloproliferative, clonal and acquired hematological disease that is included within myeloproliferative neoplasms (WHO 2016). Its main characteristic is the presence (95% of the

cases) of a small chromosome denominated Philadelphia chromosome, coming from the reciprocal translocation between the chromosomes 9 and 22. Depend where the break-point occurs, different isoforms of the fusion gene BCR-ABL may appear. For the diagnosis of CML, detection of BCR-ABL rearrangement is crucial; and molecular biology techniques, such as RT-PCR, may be the only data at that point, but most current RT-PCR methods for detecting BCR–ABL are designed and optimized for detecting the majority forms (e14a2 and e13a2) without distinguishing between them. Characterization of the transcript is not necessary for the diagnosis but permits follow-up at the molecular level and differentiate between different BCR-ABL isoforms at the time of the CML diagnosis could be taken into account in future studies to investigate its role into the prognosis.
Aims: To develop a new multiplex RT-PCR method coupled to fragment analysis by capillary electrophoresis to identify different BCR-ABL isoforms: e13a3, e19a2, e14a3, e6a2, e1a3, e13a2, e14a2, e1a2 and e8a1.
Methods: 34 CML patients BCR-ABL positive by qRT-PCR and 1 negative control for BRC-ABL fusion gene were included in this study. Three hundred nanograms of total RNA from leucocytes were used for retro-transcription (SuperScript ® IV). Subsequently, Multiplex PCR reactions were assessed using primers described by Burmeister in 2008 [ABL-3 primer labeled with carboxyferrescein (FAM)]. G6PD was chosen as endogenous gene control using G6PD-F labeled with hexachloro-fluorescein phosphoramidite (HEX). Capillary electrophoresis of the multiplex RT-PCR reaction was done in an ABI3130XL analyzer, using ILS600 as marker.
Results: BCR-ABL fusion RNAs were detected in all patients (34/34), on the other hand we did not detect BCR-ABL on the negative control. The main isoform identified was e14a2 (detected in 22 out of 34 patients, 64.7%). Twelve patients were positive for e13a2 BCR-ABL isoform (35.3%). Interestingly we identified 7 patients (20.5%) with co-expression of e14a2 and e13a2 isoforms, being in all these cases the e14a2 isoform mainly expressed.
Summary/Conclusions: RT-PCR combined with capillary electrophoresis is revealed as a sensitive technique for the detection of different isoforms of BCR-ABL and may be included as a BCR-ABL first screening. Quantification with qRT-PCR might only be done in positive samples. Unfortunately we could not detect any isoform besides the majority ones, due to the size of our cohort. Finally, our study validates previous studies on the main BCR-ABL isoforms (e14a2 and e13a2) percentage detected in CML patients.

PDGF AND BDNF PLASMA LEVELS IN CML PATIENTS BEFORE AND AFTER INITIATION OF TKI THERAPY

Z. Litwińska[1,*], K. Łuczkowska[1], E. Pius-Sadowska[1], A. Sobuś[1], E. Paczkowska[1], B. Machaliński[1]
[1]Department of General Pathology, Pomeranian Medical University, Szczecin, Poland

Background: Chronic myeloid leukemia (CML) is a malignant myeloproliferative neoplasm, which is characterized by t(9;22)(q34.1;q11.21) translocation, also known as the Philadelphia chromosome (Ph). The resulting fusion gene *BCR-ABL1* encodes a constitutively active tyrosine kinase that dictates the pathophysiology of CML. Tyrosine kinase inhibitors (TKIs) have been shown to efficiently inhibit not only the Bcr-Abl kinase, but also act on other cell surface tyrosine kinase receptors, such as the platelet-derived growth factor receptor (PDGF-R). Similar receptors are vital in neurotrophin-mediated signaling pathways, for example TrkB receptor for brain-derived neurotrophic factor (BDNF). PDGF is a potent mitogen for cells of mesenchymal origin and plays a significant role in angiogenesis, a process which has recently been recognized as crucial in growth and survival of neoplastic cells of the hematopoietic system. BDNF acts on certain neurons of the central nervous system and the peripheral nervous system and has a wide role in neuroprotection and neuroregeneration. However, the exact roles of PDGF, BDNF and their receptors in normal and malignant hematopoiesis remain unclear.
Aims: In this study we aimed to investigate the levels of PDGF-AA and BDNF in plasma from CML patients and, where possible, to identify how TKI treatment affects these proteins levels.
Methods: Peripheral blood samples were obtained from newly diagnosed CML patients (n=5), CML patients treated with TKIs (n=5) and healthy controls (n=10). Informed consent was obtained from all subjects included in the study. Plasma PDGF-AA and BDNF levels were analyzed using Luminex technology with Human Neurodegenerative disease Panel 3 kit (Merck Millipore, Billerica, USA).
Results: We have observed that PDGF-AA levels were elevated in CML group (both before and during TKI treatment) compared to controls. Interestingly, we have noticed that PDGF-AA level for newly diagnosed CML patients was higher compared to TKI-receivers ($p < 0,05$). In case of BDNF, we have observed subtle changes between the tested groups: BDNF level in newly diagnosed CML subjects was lower compared to controls ($p < 0,05$), but in TKI-receivers the level was comparable to control group ($p > 0,05$). We have also tested one patient in subsequent time points (at diagnosis, 3 months with TKIs, 6 months with TKIs) for both PDGF-AA and BDNF - we have observed PDGF levels drop and BDNF rise with time.
Summary/Conclusions: In our study we have demonstrated that PDGF-AA and BDNF are feasible targets for plasma proteomic analysis in CML patients, both for studying general patterns of protein expression and also for identifying proteins differentially expressed before and during TKI treatment. We have shown that PDGF level drops down after TKI treatment, while on the opposite BDNF level in plasma raises with time in CML patients receiving TKIs. We have also monitored these proteins levels over time in the same subject, but this requires a larger study group to draw meaningful conclusions. Further studies are required to elucidate the PDGF, BDNF and possibly other growth factors, neurotrophins and their receptors role in normal and malignant hematopoiesis.

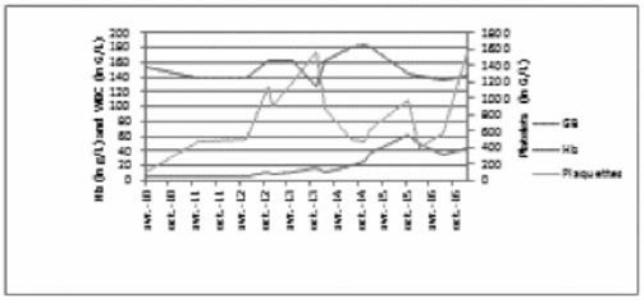
PB1813

A CASE OF ATYPICAL CHRONIC MYELOID LEUKEMIA WITH LATE DISCOVERY OF JAK2

M. Dudez[1,*], M. Daniel[1], A. Belahbri[2], B. Foucher[3], S. Girard[4], S. Hayette[5], I. Tigaud[6], L. Vila[4]
[1]Laboratory of Hematology, GHEST lyon, Bron Cedex, [2]Service d'oncohematology, Centre léon Bérard, [3]laboratory of hematology, Hôpital Desgenettes, Lyon, [4]laboratory of hematology, GHEST, BRON, [5]Departement of Cytogenetics and molecular biology, [6]Department of cytogenetics and molecular biology, GHSUD, Lyon, France

Background: Myeloproliferative neoplasms (MPN) include on the one hand chronic myeloid leukemia defined by the presence of Philadelphia chromosome and BCR-ABL remodeling, and on the other hand MPNs without Philadelphia chromosome (Polycythemia vera [PV], essential thombocythemia [ET] and primary myelofibrosis [PMF]). V617F JAK2 mutation is the main recurring genetic abnormality in these pathologies (1). It can be found in 95% of PV and 50% of ET and PMF (2). The 2016 WHO classification makes no proposal of an entity which would include BCR-ABL+and V617F JAK2+CML. However 28 of those cases were described in a 2013 literature review (9). Most patients developed either a V617F JAK2 mutation during treatment by tyrosine kinase for a BCR-ABL+CML; or a BCR-ABL+CML during treatment for a V617F JAK2+MPN (3,4,5,6,7). A very small number of patients showed coexistence of those two mutations (8).
Aims: We report a 62y old woman patient with chronic myeloid leukemia with late discovery of JAK2.
Methods: *Clinical presentation:* A 62-year-old man with no notable medical history was admitted in 2009 for CML. After failure of a first line treatment by Imatinib in 2009 (poor tolerance and incomplete molecular response), treatment by Nilotinib was initiated in 2012 allowing for, to this day, good molecular response despite poor digestive tolerance in the form of dyspepsia. Ever since 2012, the patient has had thrombocythemia (platelets: 826 G/L) followed then by polycythemia (Hb: 16.7–19 g/dL) that were first attributed to hemoconcentration and inflammation due to recurring bacterial urinary tract infections. Neither infiltration of the lymph nodes nor organomegaly had been noted. In 2014, the patient complained of abundant sweating in the absence of any fever and, despite the ongoing complete molecular response, hyperleukocytosis was observed (see Figure 1A). In 2015 the patient, then aged 68, signaled weight loss of 10 kg despite decent overall state of health. Tomodensitometry found evidence of hepatosplenomegaly. Taking into account the symptoms and persisting blood count abnormalities (WBC 27.7 G/L, Hb 182 g/L, Platelets 479 G/L, Neutrophils 22.4 G/L, erythromyelemia) a second MPN was suspected. V617F JAK2 mutation was found positive and treatment by Hydrea for essential thrombocythemia was initiated. Adaptation of Nilotinib posology was decided to avoid possible cytopenia due to its association with Hydrea.
Results: *Evolution:* (see Figure 1B) As of the last follow-up consultation in 2017, BCR-ABL remains undetectable and the overall state of health was preserved. Hyperleukocytosis as well as myelemia were persistent on the blood count whereas hemoglobin and platelets had normalized. To determine whether or not V617F JAK2 mutation was present at the time of CML diagnosis, a 2009 sample, in which JAK2 V617F had been estimated at less than 1%, was reanalyzed by means of molecular biology in January 2017.
This exam found the mutation in quantities below the clinical significance threshold (1%). But this positivity, however small (0.19%), shows preexistence of the pathological clone.
Summary/Conclusions: This patient's case can be integrated in the series of cases described in 2013 by Park *et al.* (9) as it consists of V617F JAK2 positive ET onset during treatment for a BCR-ABL positive CML. The physiopathology of those two pathologies has not yet been genetically determined (8). Are those two independent pathologies or do they share a common tumoral clone? In this case JAK2 and BCR-ABL evolved in negative correlation and as such it is surmised that there were in fact two independent diseases, with two preexisting pathological clones at the time of the first diagnosis, treatment of the first pathology having been responsible for the proliferation of the second clone.

A) evolution of white blood cells count, hemoglobin and platelet count from April 2010 to October 2016



B) evolution of BCR-ABL transcript and V617F JAK2 mutation from 2009 to 2016

E14A2 TRANSCRIPT IS ASSOCIATED WITH HIGHER PROBABILITY OF DURABLE TREATMENT FREE REMISSION IN CML PATIENTS

M. D'Adda[1,*], F. Schieppati[1], E. Morello[2], G. Ruggeri[3], E. Cerqui[1], S. Ferrari[1], C. Bottelli[1], A. Passi[1], G. Rossi[1]
[1]Hematology, [2]USD Centro Trapianto Midollo Adulti, [3]Laboratorio Analisi, ASST Spedali Civili di Brescia, Brescia, Italy

Background: TKIs discontinuation in CML-CP patients with deep molecular response (DMR) are feasible, safe and 40-60% of them maintain treatment free remission (TFR); sokal risk score and duration of TKI-therapy were significantly associated with molecular relapse, according to Euro-Ski and STIM1 trials. While it is known that patients with e14a2 achieve earlier, deeper and more durable responses compared to those with e13a2, few information is available on the influence of the type of bcr-abl transcript on TFR duration
Aims: Here we describe our single center experience of TKI discontinuation in CML-CP patients with sustained DMR
Methods: Bcr-abl transcripts were determined by RQ-PCR analysis performed in accordance with EAC protocol (Gabert et al, Leukemia 2003) and to the standards of the Italian national network Labnet. All 174 CML-CP patients presently followed at our institution according to ELN guidelines and treated with 1st or 2nd TKIs were analysed: 103 (59%) had e14a2 and 69 (40%) e13a2 transcript (in 2 pz bcr-abl were not detectable). Criteria for TKI discontinuation was sustained DMR (MR4 or better) for at least 2 years. After TKI withdrawal, RQ-PCR for BCR-ABL was performed every month during the first year and every 2 months thereafter. TKI treatment was reintroduced immediately if DMR loss occurred. TFR was defined as the time between the date of TKI cessation and the date of restarting treatment for DMR loss or, if TKI was not resumed, the date of the last contact.
Results: Forty-nine patients, 25 male and 24 female, discontinued TKI treatment. At the time of discontinuation median age was 63 years (43-85), median time from TKI start 113 months (30-172), median duration of sustained DMR 60 months (24-153). Sokal distribution was 49%, 29% and 20% for low, intermediate and high risk (one patient was not evaluable). Among our 174 patients 39% (40/103) of all e14a2 patients and 13% (9/69) of all e13a2 discontinued TKI (P 0.0002, chi square). Thirty-six patients discontinued imatinib (11 of them with previous INF treatment), 13 stopped nilotinib (8 in first line, 5 in second line treatment). Median follow up after treatment discontinuation was 19 months (3-76), including 31 patients with follow up > 12 months. Thirteen (26%) patients lost DMR. Median time off-therapy for these patients was 3 months (2-8), and only 1 lost DMR after 6 months. Therapy was restarted in all 13 patients (2 in MR1, 4 in MR2, 7 in MR3), 10 achieved a second DMR after a median interval of 2 months (1-7); 2/13 patients are in M3 after 7 and 12 months, 1 patient is not yet evaluable. Univariate analysis showed no difference in relapse risk according to age, gender, type and duration of TKI, duration of stable DMR and sokal score risk. Ten out of 11 patients treated with INF before imatinib remained in TFR. Of note, the type of bcr-abl transcript was significantly linked to DMR loss: after TKI discontinuation, 32/40 e14a2 patients (78%) maintained DMR *vs* 4/9 e13a2 patients (42%) (p 0.03). After 12 months 78% (+/-6% CI95%) of e14a2 and 41,6 (+/-17% CI95%) of e13a2 patients were still in TFR (log-rank: P=0.033) (see Figure 1). Using multivariate analysis the type of bcr-abl transcript and previous INF treatment correlated with DMR loss (p 0.012 and p 0.033). One patient died during follow up in DMR for CML-unrelated cause.

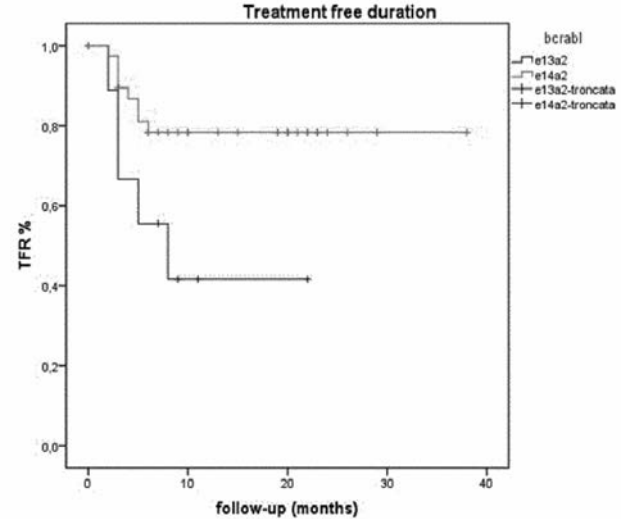

Figure 1.

Summary/Conclusions: In e14a2 CML patients the probability of discontinuation for sustained DMR is significantly higher as compared with e13a2 patients. Moreover, after discontinuation, e14a2 have significantly lower probability of DMR loss than e13a2. These data confirm that e14a2 transcript is associated with a more favorable CML disease profile than e13a2 (Jain *et al.*, Blood 2016); in addition they show that e14a2 is a favorable prognostic factor for TFR maintenance

COMPARATIVE ANALYSES OF NILOTINIB *VS* HIGH-DOSE IMATIB *VS* SUSTAINING STANDARD-DOSE IMATINIB IN PATIENTS WITH CP CHRONIC MYELOID LEUKEMIA FOLLOWING SUBOPTIMAL MOLECULAR RESPONSE TO FIRST-LINE IMATINIB

S.-E. Lee[1,2,*], S.-Y. Choi[1], S.-H. Kim[1], R. Woodman[3], T. Szczudlo[3], S. Jootar[4], H.-J. Kim[5], S.-K. Sohn[6], J. S. Park[7], S.-H. Kim[8], D.-Y. Zang[9], S.-J. Oh[10], D.-W. Kim[1,2]

[1]Leukemia Research Institute, The Catholic University of Korea, [2]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of, [3]Novartis Pharmaceuticals Corporation, East Hanover, United States, [4]BMT Program, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, [5]Chonnam National University Medical School, Chonnam National University Hwasun Hospital, Hwasun, [6]Kyungpook National University Hospital, Daegu, [7]Ajou University School of Medicine, Suwon, [8]Dong-A University, College of Medicine, Busan, [9]Hallym University College of Medicine, Anyang, [10]Kangbuk Samsung Hospital, Seoul, Korea, Republic Of

Background: Imatinib (IM) and its generic form are widely used as one of the standards of care for chronic phase (CP) chronic myeloid leukemia (CML). Although 7-year data by the IRIS demonstrated the long-term prognostic value of molecular response at specific time points, achieving major molecular response (MMR) at 18 months showed minimal event-free survival (EFS) benefit, compared with not achieving MMR but having complete cytogenetic response (CCyR). In addition, the best treatment for these patients remains less clear.
Aims: In this study, we investigated the efficacy of nilotinib (NIL) *versus* high-dose IM *versus* sustaining standard-dose IM for the patients in CCyR with suboptimal molecular response to first-line IM therapy.
Methods: Early CP CML patients who have achieved CCyR but not MMR after 18 to 24 months on first-line IM therapy at a daily dose of 400 mg were divided into the three treatment groups; nilotinib (NIL) 400mg BID (800 mg/day; group 1) *vs* IM 400 mg BID (800 mg/day; group 2) *vs* IM 400mg QD (400mg/day; group 3). Group 1 and 2 patients were selected in the RE-NICE multicenter study, in which crossover to the alternate treatment arm was allowed for patients failing to achieve a MMR at 12 months and for intolerant patients, and for patients who lost MMR at any time of treatment. Group 3 patients who have achieved CCyR but not MMR after at least 18 months of first-line IM therapy were selected from the Asia CML Registry (ACR) database system with the same inclusion criteria of RE-NICE. The efficacy endpoints are MMR rate by 12 months and MMR rate and undetectable molecular residual disease (UMRD) rates by 36 months.
Results: With a data cut-off date of 07 Dec 2016, a total of 108 patients were evaluated; 28 patients in NIL group (group 1), 28 patients in high-dose IM group (group 2), and 52 patients in standard-dose IM group (group 3). Median follow-up duration from enrollment was 36 months (range, 1-36), 45 months (range, 21-63), and 90 months (range, 14-159) for each group, respectively. All patients in group 1 remained NIL treatment, 18 patients in group 2 crossed over to NIL 400mg BID due to intolerance (n=4) and lack of response (no MMR after 12 months; n=14), in group 3, 22 patients switched to other treatment due to intolerance (n=7), lack of response (no MMR; n=12), failure (n=1), or treatment-free remission trial (n=2) and 2 patients lost to follow-up. When data on patients who crossed over to the other treatment was included, cumulative incidence (CI) of MMR by 36 months was significantly higher in group 1 than group 3 (83.1% *vs* 57.1%, P=0.021), but there was no different in group 1 *vs* 2 (P=0.195) and group 2 *vs* 3 (P=0.297). CI of $MR^{4.5}$by 36 months showed a trend of higher in group 1 than the other two group (11.7% *vs* 0% *vs* 2.6%, group 1 *vs* 2, P=0.066, group 1 *vs* 3, P=0.099, group 2 *vs* 3, P=0.405).
Summary/Conclusions: NIL 400mg twice daily treatment showed better efficacy than standard-dose IM for the treatment of patients who have suboptimal molecular response to first-line IM. Additionally, a switch to NIL in suboptimal molecular responder to IM had a trend for achieving a $MR^{4.5}$more frequently, suggesting the potential benefit of a treatment-free remission.

PB1816

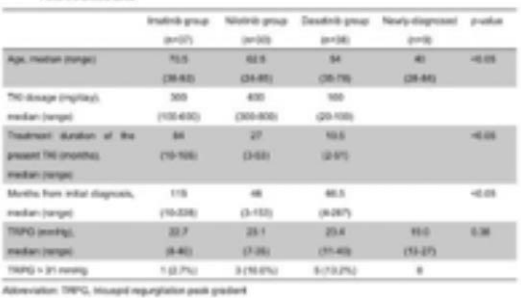
COMPARATIVE ANALYSIS OF PULMONARY HYPERTENSION IN THE 105 CML PATIENTS TREATED WITH IMATINIB, NILOTINIB AND DASATINIB

M. Minami[1,*], T. Miyamoto[1], K. Akashi[1]

[1]Department of Medicine and Biosystemic Science, Kyushu University, Fukuoka City, Japan

Background: Pulmonary hypertension (PH) has been reported as a serious adverse event in chronic myeloid leukemia (CML) patients treated by dasatinib. French group reported incidence of PH diagnosed by cardiac catheterization as 0.45% (13 of 2,900 patients) in symptomatic patients treated with dasatinib. Dasatinib-related PH usually resolves after cessation of treatment, but it can be fatal, as two deaths in France and one in Japan have been documented.
Aims: To clarify the incidence of tyrosine kinase inhibitor (TKI)-related PH, we noninvasively screened CML patients who have been given imatinib, nilotinib or dasatinib by echocardiography.
Methods: 105 patients with CML in chronic phase (CP) who received TKI were enrolled in this study between 2014 and 2015. Nine patients with newly diagnosed CML in CP prior to TKI treatment were added as control. Patients underwent echocardiography to evaluate values of tricuspid regurgitation pressure gradient (TRPG), which relates to severity of PH. Patients with TRPG values >31mmHg were suspected of PH onset according to European Society of Cardiology criteria. All patients gave informed consent.
Results: Patients were divided into 3 groups by the TKIs they used at the time of study enrollment; 37 patients on imatinib, 30 on nilotinib and 38 on dasatinib (Table 1). In imatinib group, patients' age was significantly higher, and duration of treatment was also longer than those of the 2nd generation TKIs. Echocardiography revealed mean values of TRPG as 22.7, 23.1 and 23.4mmHg in imatinib, nilotinib and dasatinib groups, respectively (p=0.887), and these values were higher than that in the newly diagnosed CML patients (19.0mmHg), though without significance (p=0.38). Nine of the 105 patients (8.6%) presented with an elevated TRPG>31mmHg, suggesting the presence of PH; 1 of 37 (2.7%) in imatinib group, 3 of 30 (10.0%) in nilotinib group, and 5 of 38 (13.2%) in dasatinib group. Three patients complained of dyspnea, while the remaining 6 were asymptomatic. We found no apparent risk factors associated with TRPG elevation, however, there were trends toward correlation of age and TRPG values in nilotinib and dasatinib treated patients, and treatment duration and TRPG values in nilotinib treated patients. Imatinib dosage tended to inversely correlate with TRPG value, suggesting that imatinib might decrease pulmonary arterial blood pressure in a dose-dependent manner.

Table 1.



Patient characteristics					
	Imatinib group (n=37)	Nilotinib group (n=30)	Dasatinib group (n=38)	Newly diagnosed (n=9)	p-value
Age, median (range)	73.5 (38-83)	62.5 (34-85)	54 (26-79)	40 (28-84)	<0.05
TKI dosage (mg/day), median (range)	300 (100-400)	400 (300-800)	100 (20-100)		
Treatment duration of the present TKI (months), median (range)	84 (10-105)	27 (3-53)	10.5 (2-97)		<0.05
Months from initial diagnosis, median (range)	119 (10-338)	46 (3-113)	66.5 (4-267)		<0.05
TRPG (mmHg), median (range)	22.7 (8-40)	23.1 (7-35)	23.4 (11-40)	19.0 (13-27)	0.38
TRPG > 31 mmHg	1 (2.7%)	3 (10.0%)	5 (13.2%)	0	

Abbreviation: TRPG, tricuspid regurgitation peak gradient

Summary/Conclusions: PH is a rare but life-threatening adverse event for dasatinib-treated patients, and its definitive diagnosis is made by cardiac catheterization. However, cardiac catheterization is too invasive for PH screening of the many patients with TKIs who do not have any symptoms. Our study, by using echocardiography, detected TRPG elevation not only in dasatinib treated patients (13.2%) but also in imatinib (2.7%) and nilotinib (10%), including patients without any symptoms. This indicates possible PH onset among patients treated with imatinib or nilotinib, as well as with dasatinib. Although TRGP values obtained by echocardiography might not be fully compatible with those by cardiac catheterization, the results suggested that noninvasive echocardiography is sensitive for screening PH and is also effective for easily screening groups of patients with suspect subclinical PH among patients treated with any available TKIs. Careful screening with echocardiography is necessary especially for older patients who have received TKIs for a long time.

PB1817

DYNAMICS OF BCR-ABL1 MUTATION ACQUISITION AND LONG-TIME MUTATION ASSOCIATED RESISTANCE PROGNOSIS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED BY TYROSINE KINASE INHIBITORS: RUSSIA, 2006-2016

V. Tikhonova[1,2,*], Y. Finashutina[1], L. Kesaeva[1], Y. Stroylova[3], N. Kasatkina[1], E. Misyurina[4], A. Misyurin[1,2]

[1]Lab of recombinant tumor antigens, N.N.Blokhin Russian Cancer Research Center, [2]GeneTechnology LLC, [3]RI of Molecular Medicine, I. M. Sechenov First Moscow State Medical University, [4]Clinical City Hospital 52, Moscow, Russian Federation

Background: While chronic myeloid leukemia (CML) can successfully be treated with tyrosine kinase inhibitors (TKIs), mutations in the BCR-ABL1 kinase domain are the most prevalent cause of TKI resistance. More than 100 *BCR-ABL1* kinase domain point mutations with various frequencies of incidence, domain positions and implications on TKI response in CML are associated with

TKI resistance. Here we present our data concerning prognostic significance of *BCR-ABL1* kinase domain mutations dynamics in Russian CML patients according the follow-up study having been performed during the last 10 years.
Aims: To determine the frequency dynamics of *BCR-ABL1* mutations in CML patients and its prognostic significance.
Methods: In this study we have included 1077 TKI resistant CML patients from 112 hospitals of 77 Russian cities having been observed during the period from 2006 to 2016. *BCR-ABL1* kinase domain point mutations in mRNA samples from peripheral blood cells were analyzed by means of PCR followed by Sanger sequencing. Statistical analysis was performed using SPSS 22.0 (IBM, USA) and Excel 2013 (Microsoft, USA). Critical p-value was set to 0.05.
Results: 1077 TKI resistant CML patients were analyzed, among them were 41,5% men (n=447) and 58,5% women (n=630), median age – 50 (from 15 to 74). *BCR-ABL1* mutations were found in 30,8% (332/1077) CML pts. We have detected a total of 415 mutations in 332 patients, giving rise for 58 different mutation variants. Mutation associated resistance rate was higher in women to compare with men (72,3% against 63,2%, *p=0,001*). It turned out that F317L and H396R mutations were statistically more frequent in women, meanwhile T315I mutation prevailed in men group (Pearson's χ^2<0,05). It was of a sudden that *BCR-ABL1* mutation distribution significantly varied according the particular CML pts city location throughout the different regions of Russia. Although for the period from 2006 to 2016 there were no detectable changes in mutation frequency spectrum (Pearson's χ^2 is 0,062), the total amount of mutations associated with TKI CML resistance has decreased from 36,6% in 2006-2008 to 24,95% in 2013-2016, but still remained significant. For particular mutations the following dynamics was detected: frequency of imatinib-resistant mutations decreased gradually from 2006 to 2016, while the rate of F317L and F359V mutations underlining resistance to second generation TKI increased in 2013-2016. T315I mutation rate expanded to the maximal level in 2014 and abruptly decreased afterwards. This tendency change may be the consequence of the second generation TKIs and other therapeutic strategies involvement into clinical practice.
Summary/Conclusions: As far as different BCR-ABL1 kinase domain mutations are associated with various types of mutation associated resistance to TKI treatment, the detection of trends in mutation distribution in CML patients receiving TKI treatment is very important for long time treatment strategy decision making and early prognosis of resistance. We believe here that regional difference of mutation profiles should also be considered. Therefore, to enable correct triggering of particular types of TKI for CML treatment it is necessary to obtain data of when, which and where a particular type of BCR-ABL1 mutation is prone to appear in a distinguished cohort of CML pts.

Eugenio" Hospital, Roma, [17]Chair of Hematology, AO Ordine Mauriziano, University of Torino, Torino, [18]Department of Clinical Medicine and Surgery, "Federico II" University, Napoli, [19]Department of Hematology and Clinical Oncology, University of Bologna, Bologna, Italy

Background: Chronic myeloid leukemia (CML) is driven by different transcript types, but the majority of patients have a e13a2 (b2a2) transcript, a e14a2 (b3a2) transcript or a co-expression of e13a2/e14a2 transcripts. In imatinib-treated patients, the e13a2 transcript has been associated to slower and inferior molecular responses. Few data on the prognostic impact of BCR-ABL1 transcript type in CML patients treated with second generation tyrosine kinase inhibitors (TKIs) are still available.
Aims: To assess the impact of BCR-ABL1 transcript type on molecular response and outcome in newly diagnosed adult CML patients treated frontline with nilotinib (NIL).
Methods: An analysis of 345 CML patients at diagnosis (chronic phase) enrolled within 3 multicentric prospective studies of the GIMEMA CML Working Party (NCT00481052, NCT00769327, NCT01535391) was performed. The initial treatment was NIL 300 mg BID or NIL 400 mg BID. Definitions: major molecular response (MMR), BCR-ABL1^{IS} ratio <0.1%; deep molecular response ($MR^{4.0}$), BCR-ABL1^{IS} ratio <0.01% with >10,000 ABL1 copies; progression, transformation to advanced phases; death, at any time and for any reason. Cumulative incidences of response were estimated under consideration of competing risks (progression, death) and compared by Gray test. Progression-free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method and compared by log-rank test.
Results: Patients expressing rare transcripts (e1a2 or e19a2; n=7) and patients with unknown transcript type (n=10) were excluded: 328 patients were evaluable, 38% with e13a2 transcript, 53% with e14a2 transcript and 9% expressing both transcripts. No significant differences in age, gender, Sokal or EUTOS long-term survival score distribution, presence of clonal chromosomal abnormalities in Ph+ cells, or NIL dose were observed. The median follow-up was 60 months (range 24-82 months). The response rates and the survival probabilities were uniformly lower in patients with e13a2 transcript (N=124) compared to patients with e14a2 transcript (N=174), but the differences were not significant: MMR by 12 months, 66% *vs* 72%, p=0.244; $MR^{4.0}$ by 36 months, 56% *vs* 66%, p=0.067; estimated cumulative incidence of MMR, 82% *vs* 88%, p=0.135; estimated cumulative incidence of $MR^{4.0}$, 60% *vs* 69%, p=0.101; estimated PFS, 88% *vs* 93%, p=0.547; estimated OS, 89% *vs* 94%, p=0.436. The responses and the survival probabilities of patients co-expressing the e13a2 and the e14a2 transcripts (N=30) were similar to or even better than the ones of e14a2 patients. Grouping together the patients with e14a2 transcript alone and the patients with co-expression of both transcripts (N=174+30=204), and comparing them to patients with e13a2 transcript alone (N=124), the response differences were significant (cumulative incidence of MMR and $MR^{4.0}$, p=0.050 and p=0.036, respectively), but no outcome differences emerged (PFS and OS, p=0.340 and p=0.276, respectively).
Summary/Conclusions: Lower molecular response rates in patients with e13a2 transcript were observed, but the differences were small and mostly not significant. No outcome differences were detected. Further studies in larger patient cohorts are required in order to clarify whether including the transcript type in the calculation of the baseline risk scores may improve prognostic stratification, and whether NIL or other second generation TKIs should be preferred as first-line therapy in patients aiming at treatment-free remission.

Medizinische Klinik, Universität Heidelberg, Medizinische Fakultät, Mannheim, Germany, [13]Division of Hematology and Hematologic Malignancies, Huntsman Cancer Institute, The University of Utah, Salt Lake City, United States

Background: Imatinib (IM) monotherapy remains an acceptable option to treat newly diagnosed patients with chronic myeloid leukemia (CML) in the chronic phase (CP). Hydroxyurea (HU) is effective in controlling elevated white blood cell counts and has been widely used to treat CML prior to the era of tyrosine kinase inhibitors (TKIs). The combinations of IM and HU have been tested *in vitro* and showed a additive suppression of CML CFU-GM cells. Combinations of IM and cytotoxic agents such as cytarabine have been tested also in vivo, but no data are available for the combination of IM and HU in CML.
Aims: The East German Study Group conducted a phase I study to identify the dose of HU in combination with standard dose IM (400mg daily) that would result in mild myelosuppression (white blood cell count 3,000-4,000/mL). Starting dose of HU was 500mg daily which was increased by 500mg every 3 weeks to a maximum of 3,000 mg daily. According to protocol, 500mg HU was identified as the starting dose for the randomized phase II study which tested the combination *vs* standard dose IM, with the rate of major molecular response (MMR) at 18 months as the primary endpoint.
Methods: Starting in 2002, 20 adult patients with newly diagnosed CP-CML were included in the phase I study. Additional 93 patients were enrolled in the phase II of the study, 5 of whom were excluded. With ratio 2:1 in phase II, 88 patients were randomized to the IM/HU (n=59) and IM (n=29) arm, respectively.

Three patients (2 IM/HU, 1IM) were lost to follow-up. As prospectively designed, all available IM/HU patients (n=77) were analyzed together. According to the study protocol, patients from the CML IV study were to be added to obtain equal numbers for analysis. To arrive at a total of 77 IM patients, from study IV another 49 patients were selected by propensity score matching. The median age of the 154 patients was 55 years (range 18 – 82). The ELTS prognostic score was available for 141 patients and was high in 8 (5.7%), intermediate in 35 (24.8%) and low in 98 (69.5%), with no significant differences between treatment groups.

Results: The 5-year overall survival (OS) / progression-free survival (PFS) probabilities were 90.4 and 86.7% in the IM/HU and twice 84.9% in the IM arm (p=not significant). With IM/HU, the probabilities of complete cytogenetic response (CCR) at 6, 12, and 18 months were 54.3, 84.0, and 93.7%. In the IM arm, the corresponding numbers were 70.4, 84.9, and 83.3% (p=not significant). Primary endpoint was MMR rate at 18 months. There was no significant difference between IM/HU (65.8%) and IM (66.0%). At 6 months, MMR rates were 21.6 (IM/HU) *vs* 41.1% (p=0.0383) and at 12 months 41.9 (IM/HU) *vs* 58.9% (not significant). Time to event analyses of OS and PFS did not result in significant differences; neither did group comparisons between the probabilities of CCR and MMR. The median HU dose was 500mg (range 152-3000); the median IM dose was 400 mg (range 145-617mg) in both arms. The gross numbers of adverse events in general or of adverse events of grade 4 were not different between the two arms, but cumulative incidences showed an earlier occurrence in the IM/HU than in the IM arm (p= 0.0343, Gray test)

Summary/Conclusions: Compared to Imatinib only, the combination of Imatinib and HU resulted in a lower MMR rate at 6 months but a similar MMR rate at 18 months. Furthermore, IM/HU was associated with more early adverse events. There was no indication of a beneficial effect in the treatment of CML patients in 1st chronic phase using the combination of IM with HU.

PB1820

A MULTICENTER, OBSERVATIONAL, AMBISPECTIVE STUDY EVALUATING EFFICACY AND SAFETY OF GENERIC IMATINIB COMPARED TO GLEEVEC IN CHRONIC MYELOGENOUS LEUKEMIA IN CHRONIC PHASE - 3 MONTHS RESPONSE ANALYSIS

K. Pagnano[1,*], E. Miranda[1], N. Clementino[2], G. Magalhães[2], A. Coelho[3], I. Bendit[4], F. Seguro[5], M. Nicolau da Silva[3], C. Boquimpani[6], L. Fogliatto[7], J. Bortolini[8], C. Pinna[9], M. D. L. Chauffaille[10], R. Centrone[11], C. De Souza[12]

Background: The efficacy of branded imatinib (Gleevec) in the first-line treatment of chronic myeloid leukemia (CML) has been demonstrated in several clinical studies. However, there are few consistent data in the literature on the efficacy and adverse effects of generic formulations of imatinib. In Brazil, CML patients have been treated in the national public health system with generic imatinib since June 2013.

Aims: The present study aims to evaluate the efficacy and safety of generic imatinib in the treatment of CML in comparison with the reference drug (Gleevec) in the first three months of imatinib treatment.

Methods: This is a multicenter, observational, ambispective, cohort-type study. The study was initiated in January 2015 with the intended participation of 17 Brazilian centers. In the prospective group, were selected chronic phase CML patients who started their first-line treatment with generic imatinib between January 2015 and October 2016, whereas retrospective group was treated with Gleevecbetween January 2010 and December 2011. All patients started imatinib less than six months from diagnosis. Study data were collected and managed using REDCap electronic data capture tools. Demographic data were collected at diagnosis: age, gender, Sokal, Hasford, EUTOS score, comorbidities, cytogenetics, BCR-ABL transcript type. The definition of the responses followed the European Leukemia Net 2013 criteria. Adverse events were assessed based on the Common Terminology Criteria for Adverse Events (CTCAE) Version 4.0.3, 2010. Statistical analysis: SPSS version 21.0 was used applying the chi-square and t-test, when adequate. All analysis considered p-value <0.05 as significant.

Results: Ten centers have registered 177 patients in the retrospective group and 68 patients in the prospective group so far. For this preliminary analysis, response data from 132 patients were available (47 from prospective and 85 from the retrospective groups). The median age of patients was 54 years in the prospective group and 46 years in the retrospective group (P=0.12). Sokal score in prospective and retrospective groups, respectively: low risk 42%/52%; intermediate risk 42%/31% and high risk 45%/67% (P=0.48). There was no difference between the groups concerning gender, Hasford, EUTOS scores, ECOG, blood cell counts at diagnosis and before starting imatinib and BCR-ABL transcripts. Regarding responses, there was no difference in the hematological, complete cytogenetic responses and rate of BCR-ABL transcripts >10% at three months. However, there was a higher rate of failure at three months according to the ELN 2013 criteria in the prospective group (14.9% *versus* 4.7% Gleevec group, P=0.04). There was no significant difference in grade 3 and 4 hematological and non-hematological toxicity, but there was one early death in the prospective group (acute peripheral arterial occlusion and renal failure). Four patients discontinued imatinib: one from Gleevec group (resistance) and three from the generic group due to intolerance (1) and resistance (2).

Summary/Conclusions: According to ELN-2013 criteria, there was a higher rate of failure in the prospective group (generic Imatinib) at three months, but no difference in toxicity. The register is ongoing; the confirmation of this data and the impact in prognosis will be evaluated in the long-term follow-up, after increasing the number of patients.

COMPLEX ADDITIONAL CHROMOSOME ABERRATIONS IN PH-POSITIVE CELLS IMPACT ON CHRONIC MYELOID LEUKEMIA PATIENTS' SURVIVAL IN THE ERA OF TYROSINE KINASE INHIBITORS

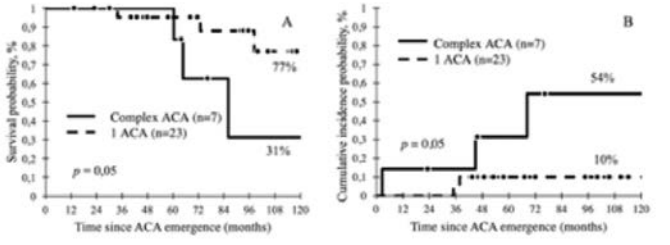
M. Fominykh[1,*], O. Shuhov[2], I. Martynkevich[1], V. Shuvaev[1], E. Chelysheva[2], A. Turkina[2]
[1]Clinical department, Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, [2]Clinical department, National Research Center for Hematology, Moscow, Russian Federation

Background: Additional chromosomal aberrations (ACA) as marker of clonal evolution in chronic myeloid leukemia (CML) patients were previously noted in association with resistance to therapy. The presents of ACA have been associated with a worse prognosis for survival in the pre-TKI era. The ACA classification proposed earlier was based only on its frequencies. Whereas ACA's clinical impact had not yet been clearly established.

Aims: The aim of our study was to evaluate the long-term impact of the ACA presence in Ph-positive cells in CML patients on TKI treatment results.

Methods: 30 patients with ACA in Ph-positive cells treated in our center from 2005 to 2015 years were included in this study. Cytogenetic analyses of at least 20 Giemsa-banded bone marrow metaphases were interpreted per ISCN 2013. We analyzed overall survival (OS) and cumulative incidence of CML-related death on TKI treatment. Cox regression was used for multivariate survival analysis, that included next covariates: number of ACA, type of ACA, age, TKI type, CP or AP at diagnosis. OS was estimated by Kaplan-Meier method with log-rank test for comparison. Cumulative incidence of CML-related death was estimated into consideration the presents of competing risks (CML-unrelated death) using Gray's test for comparison between groups.

Results: Median follow-up period in ACA group (n=30) was 51 months (3-124). ACA at diagnosis were detected in 16 (53%) of 30 patients. Chronic phase CML at diagnosis was determined in 23 (77%) patients. Imatinib was used as first-line in 20 (67%) patients, 3 (10%) patients were initially treated with Nilotinib. Accelerated phase was defined in 7 (23%) patients. In that group treatment of 6 patients was started with Imatinib and Dasatinib was given initially for one patient. «Major-route» ACAs (trisomy 8, +der(22)t(9;22)(q34;q11), i(17)(q10), trisomy 19,) were detected in 16 (53%) of 30 patients. Complex aberrations (2 ACA and more) were revealed in 7 (23%) patients, 4 patients from this group had «major-route» ACA. 10-years OS in the whole ACA group was 67%, 10-years cumulative incidence of CML-related death was 23%. Number of ACA (p=0.03, HR=13.2) and age (p=0.03, HR=1.14) had statistical significance influence on survival by regression analysis. 10-years OS was 31% and 77% (p<0.05) in patients with complex ACA and single ACA respectively, 10-years cumulative incidence of CML-related death was 54% for patients with complex aberrations *versus* 10% for single ACA patients (p<0.05) (Figure 1).



Overall survival (A) and cumulative incidence probability of «death due to CML» (B) in CML patients with complex ACA (n=30)

Figure 1.

Summary/Conclusions: Our results showed that TKI treated CML patients with complex ACAs have a higher risk of progression and death in comparison with single-ACA patients.

PB1822

BCR/ABL1 TRANSCRIPT E13A2 IS ASSOCIATED WITH HIGHER CUMULATIVE PROBABILITY OF LOSS OF MAJOR MOLECULAR RESPONSE IN CML PATIENTS TREATED WITH NILOTINIB AS THE 2-ND LINE THERAPY

I. Dmytrenko[1,*], V. Fedorenko[1], Z. Martina[2], V. Sholoyko[2], T. Shlyakhtychenko[1], Z. Minchenko[1], I. Dyagil[2]
[1]Immunogenetic Laboratory, [2]Hematology and Transplantology Department , National Research Center for Radiation Medicine, Kyiv, Ukraine

Background: Several types of transcripts can be produced during chromosomal translocation, which lead to formation of the BCR/ABL fusion gene in patients with chronic myeloid leukemia (CML). Previous results of a few large studies showed that patients with CML in chronic phase (CP) with e13a2 transcript have inferior responses to frontline imatinib therapy compared to patients with the e14a2 transcript.
Aims: To investigate the prognostic significance of e13a2 and b14a2 BCR/ABL1 transcripts in CML patients switched to nilotinib after suboptimal response or failure on frontline imatinib.
Methods: CP-CML patients (N=143) who did not achieve complete cytogenetic response (CCR) after imatinib therapy (600 or 800 mg once daily) and were switched to nilotinib 400 mg twice daily, were enrolled in present study (55 patients with e13a2 transcript and 88 patients – with e14a2 transcript). The median of imatinib treatment before switching to nilotinib was 44 months (range 1-137). A qualitative RT-PCR for BCR/ABL1 transcript was performed at diagnosis. The patients who achieved CCR but did not have major molecular response (MMR) as well as patients with rare BCR/ABL1 transcripts and coexpression were excluded from the analysis. Probability of overall survival (OS), progression-free survival (PFS) and event-free survival (EFS) were calculated using Kaplan-Meier method. Event in EFS was defined as death of a patient on treatment for any reason, progression of disease, or loss of CCR or MMR. Differences between groups were assessed using log-rank, χ2-tests and Mann-Whitney U-tests. Cumulative probability of CCR, MMR, MR4,0 (BCR/ABL<0,01%) and loss of CCR and MMR was assessed using Kaplan-Meier method.
Results: The median follow up was 23 (range 4 – 82) months. The groups with both of the BCR/ABL1 main transcripts were comparable for the disease phase, Sokal risk score and the proportion of patients with additional chromosomal abnormalities in Ph-positive cells. No correlation of transcript type with age or sex was observed. Transcript e13a2 was associated with higher WBC (120x109/L *vs* 95.3x109/L, p=0.02) and lower baseline percentage of eosinophils (p=0.041). No differences were found in other differential counts of peripheral blood, hemoglobin concentration, or spleen size.
The time to CCR, MMR and MR4,0 and rate of CCR (52% and 52%), MMR (38% and 33%) and MR4 (23% and 22%) were comparable in patients with e13a2 and e14a2 transcripts respectively. Estimated probability of CCR, MMR and MR4,0 also did not differ in both groups. The rate of optimal response, primary and secondary resistance to nilotinib therapy was comparable in both groups. Whereas there were no differences in the estimated probability of CCR loss in both groups, but rate and cumulative incidence of MMR loss was significant higher (69% *vs* 11%, p=0.037) in patients with e13a2 transcript. No difference between groups was observed with regard to PFS, EFS and OS.
Summary/Conclusions: Analisys of 143 CML patients treated with nilotinib as the 2-nd line therapy suggests that patients with e13a2 transcript have less stable therapy response and demonstrate higher cumulative incidence of MMR loss (molecular relapse). But outcome differences were nor observed. Further analysis of a larger number of events and longer observation is required.

ANALYSIS OF GENERIC IMATINIB EFFICACY IN CHRONIC MYELOID LEUKEMIA TREATMENT: MORE THAN FOUR YEARS OF EXPERIENCE IN SOUTHERN SERBIA

I. Cojbasic[1,2,*], L. Macukanovic Golubovic[1,2], M. Vucic[1,2], I. Tijanic[1,2]
[1]Medical Faculty, University of Nis, [2]Clinic of Hematology and Clinical Immunology, Clinical Center Nis, Serbia, Nis, Serbia

Background: Tyrosine kinase inhibitors (TKIs) are the golden standard in the treatment of chronic phase chronic myeloid leukemia (CP-CML) due to their high efficacy and mild toxicity profile. Because of the high price of these drugs, the use of generics is encouraged to reduce health care costs. In the literature, there is still limited data and some concerns about the effectiveness of generic imatinib (GI), although there is a growing number of countries in which it is used instead of original imatinib (OI).
Aims: The objective of this study was to evaluate efficacy and safety of GI in newly diagnosed CP-CML patients treated with frontline GI and in patients switched from OI to GI.
Methods: Cohort of 101 adult patients with CP-CML was analysed, treated with TKIs in our institution during period from August 2012 to February 2017. First group consisted of 53 patients treated with GI (Anzovip). According to European LeukemiaNet (ELN) 2013 guidelines, rate of optimum therapeutic response was analysed, as well as rate of treatment failure at 6 and 12 months. The second group consisted of 48 patients switched from OI to GI, in which the rate of achieved therapeutic response at the time of switching and the rate of maintenance of CCyR, MMR and MR4 after a minimum of 12 months under therapy with GI were both analysed. In order to investigate safety of GI, in both groups rate of hematological and non-hematological adverse effects (AEs), all grades according CTCAE criteria, were analysed.
Results: Analysis of the optimal response by ELN criteria in the group with GI showed that at 6 months 33/53 (62.3%) patients achieved CCyR, BCR-ABL<1% was in 27/52 (51.9%) patients, while 15/52 (28.8%) of patients achieved MMR. At 12 months of therapy, 35/49 (71.4%) of analysed patients achieved CCyR, and 25/49 (48.9%) achieved MMR. ELN criteria for treatment failure at 6 months fulfilled 12/53 (22.6%) patients, while at 12 months ELN criteria satisfied 13/49 (26.5%) of analysed patients. After 18 months of therapy with GI the rate of CCyR was 35/46 (76.1%) and MMR was 28/45 (62.1%) and showed trend of increase. During the median follow-up period of 23.8 months 3 patients have progressed to blast phase and total of 7 patients died. In the second group, in time of switching from OI to GI, the rates of achieved CCyR, MMR and MR4 were 82.5%, 65.8% and 49% of patients respectively. The rate of maintenance of previously achieved CCyR was 95%, of MMR 88% and of MR4 72% in the course of the median duration of GI exposure of 37.8 months. When comparing first and second group respectively, the rates of patients which have been switched to 2nd generation of TKI because of the failure or intolerance to imatinib were 27.8% *vs* 24.8%, and 60.5% *vs* 64.5% of them achieved secondary optimal therapeutic response (CCyR plus MMR), while 25% *vs* 20% of them have been sent to BMT. Group switched from OI to GI had not significantly different non-hematological AEs of all grades compared to GI group (21.7% *vs*.24.2%, p=0.991). Furthermore, the rate of grade 3-4 hematological AEs were similar in both groups (13% *vs* 15%, p=0.952).
Summary/Conclusions: Results of this study with extended follow-up of more than four years are further evidence of that the generic imatinib is at least non-inferior to the original imatinib regarding efficacy both when used initially or as a subsequent replacement for branded imatinib.

PB1824

ACHIEVING OPTIMAL RESPONSE AT 12 MONTHS IS ASSOCIATED WITH A BETTER HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA: A PROSPECTIVE, LONGITUDINAL, SINGLE CENTER STUDY

Q. Jiang[1,*], H. Wang[2], L. Yu[1], D. Milijkovic[3], X. Huang[1]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking University Clinical Research Institute, Beijing, China, [3]Novartis Pharma AG, Basel, Switzerland

Background: Health-related quality-of-life (HRQoL) profile is now recognized as an important component in the management of Chronic myeloid leukemia (CML).
Aims: To explore the HRQoL profiles of patients with CML in the chronic phase (CP) who were treated with front-line imatinib or nilotinib, in order to assess the relationship between early response and HRQoL outcomes.
Methods: A prospective, longitudinal, single center study was conducted to assess the response to treatment with imatinib or nilotinib and the HRQoL profile of patients who were newly diagnosed with CML-CP enrolled into ENESTchina study. Responses based on molecular and cytogenetic outcomes were measured according to the European LeukemiaNet recommendations, and patient-reported HRQoL profile was measured by the SF-36 health survey.
Results: Fifty-nine patients were randomly assigned to receive imatinib (n=31) or nilotinib (n=28). In multivariate analysis, the use of nilotinib was identified as an independent factor affecting the achievement of optimal response at 6 months (OR=3.9, 95% CI, 1.0-14.9; P =0.043) and 12 months (OR=5.6, 95% CI, 1.7-17.9; P =0.004). With a median follow-up of 60 months, the probabilities of failure-free survival (all P values <0.001) and progression-free survival (all P values <0.05) at 5 years were significantly higher in patients who achieved optimal response at 3, 6, or 12 months than those who achieved non-optimal response (warning or failure), and overall survival rate at 5 years was significantly higher in those who achieved optimal response at 12 months (P =0.047). Achieving optimal response at 12 months was associated with better role limitations due to physical health problems (P =0.0019) and role limitations due to emotional problems (P =0.0110) and was the sole factor associated with significantly improving physical component summary over time (P =0.0160). In addition, achieving optimal response at 6 months had a tendency of high physical functioning (P =0.0674), social functioning (P =0.0571), and role limitations due to emotional problems (P =0.0916) scores. Age <40 years, female gender, and higher education level were also associated with better HRQoL subscales.
Summary/Conclusions: Achieving optimal response at 12 months was associated not only with longer overall survival and less treatment failure and disease progression, but also better HRQoL in newly diagnosed patients with CML-CP on front-line tyrosine kinase inhibitor.

PB1825

MULTI-COUNTRY RETROSPECTIVE CHART AUDIT STUDY TO EXAMINE DEEP MOLECULAR RESPONSE (MR4.5) ASSOCIATED WITH

SECOND-LINE TYROSINE KINASE INHIBITORS IN CHRONIC PHASE - CHRONIC MYELOGENOUS LEUKEMIA (CML-CP)

J. Cortes[1,*], L. Huynh[2], P. Brandt[3], M. DerSarkissian[2], G. Zaccardelli[2], D. Dalal[3], J. Hussein[2], M. S. Duh[2]
[1]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, [2]Epidemiology, Analysis Group, Inc., Boston, [3]Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: Achieving deep molecular response, ≥4.5-log reduction ($MR^{4.5}$; BCR-ABL1 on the International Scale [IS] ≤0.0032%), is one of the important prerequisites for attempting treatment-free remission. Limited information is available on comparative rates of $MR^{4.5}$ between nilotinib and dasatinib in second-line (2L).
Aims: This study aims to investigate time to achieving $MR^{4.5}$ and major molecular response (MMR; ≥3-log reduction or ≤0.1% in BCR–ABL1 on IS) in CML-CP patients (pts) treated with nilotinib *vs* dasatinib in 2L.
Methods: An online physician panel approach was used to recruit oncologists (N=141) globally to conduct a retrospective medical chart audit. Physicians were instructed to select up to 4 pts who met the following criteria via a random letter generation scheme for the first letter of pt's last name: diagnosed with CML-CP at age ≥18 years, initiated 2L nilotinib or dasatinib between 1/1/11 and 3/1/15, and had ≥12 mos of follow-up data after initiating 1L TKI. Multivariate Cox proportional hazards models accounting for country clustering random effects were used to assess the effect of nilotinib *vs* dasatinib on time to $MR^{4.5}$ and MMR, adjusting for age, gender, Sokal risk score at diagnosis, hydroxyurea use before 1L TKI, 1st *vs* 2nd generation TKI as 1L, and reasons for 1L TKI discontinuation. Adjusted hazard ratios (HR) and 95% confidence intervals (CI) were reported. Adverse events (AEs) were also described.
Results: The study included 236 pts from Australia, Brazil, France, Germany, Italy, and Netherlands treated with nilotinib (N=115[49%]) or dasatinib (N=121[51%]) in 2L. Both groups had a similar mean follow-up of 23 mos, mean age of 57 years, and were 35% female. 8% of 2L nilotinib and 22% of 2L dasatinib pts were treated with the other 2nd generation TKI in 1L (p<0.01). A higher proportion of nilotinib pts had high-risk Sokal score (20.9% *vs* 11.6%, p=0.05) and received prior hydroxyurea (8.7% *vs* 3.3%, p=0.08) *vs* dasatinib. 85% and 11% of 2L nilotinib pts discontinued 1L TKI due to resistance and intolerance, respectively, prior to switching to nilotinib, *vs* 74% and 22% for 2L dasatinib pts (both p<0.05). The univariate Cox model showed that nilotinib had a non-significantly higher rate of achieving $MR^{4.5}$ than dasatinib (32% *vs* 31% at 24 mos for 2L nilotinib and 2L dasatinib pts, respectively, based on the Kaplan Meier estimator; unadjusted HR=1.09, 95% CI [0.87, 1.38], p=0.46); however, after multivariate adjustment, nilotinib reached a significantly higher rate of achieving $MR^{4.5}$ (adjusted HR=1.36, 95% CI [1.07, 1.73], p<0.01) than dasatinib. Among those who achieved $MR^{4.5}$, 45% of nilotinib pts maintained $MR^{4.5}$for ≥1 year *vs* 39% of dasatinib pts (p=0.60). Additionally, high-risk Sokal score (HR=0.31; 95% CI [0.14, 0.72], p<0.01) and resistance to 1L TKI (HR=0.60; 95% CI [0.42, 0.86], p<0.01) were inversely associated with achieving $MR^{4.5}$. There was no significant difference in MMR achievement between 2L TKI groups. Over 3 times more dasatinib pts experienced pleural and pericardial effusion AEs than nilotinib pts (9.9% *vs* 2.6%; p=0.02). One nilotinib pt had ischemic heart disease-related AE *vs* none for the dasatinib group (p=0.49).
Summary/Conclusions: This retrospective chart audit study suggests that 2L nilotinib may be associated with a higher rate of $MR^{4.5}$ than 2L dasatinib in CML-CP. Our results should be taken with caution as this study is susceptible to unmeasured confounding and biases due to its retrospective and observational nature. Rigorous clinical assessment in a prospective setting is needed to conclusively compare rates of patients achieving $MR^{4.5}$.

PB1826

COMPUTATIONALLY INTELLIGENT PREDICTION OF CLINICAL OUTCOME IN CHRONIC MYELOID LEUKEMIA

Z. Cojbasic[1], I. Cojbasic[2,3,*], L. Macukanovic-Golubovic[2,3], M. Vucic[3,4]
[1]Mechanical Engineering Faculty, University of Nis, [2]Clinic of Hematology, Clinical Center Nis, [3]Facuty of Medicine, University of Nis, [4]Clinic of Hematology, Clinical Ceter Nis, Nis, Serbia

Background: Computational intelligence has been applied to a wide range of problems to assist in decision-making, especially artificial neural networks, fuzzy systems and powerful hybrid neuro-fuzzy approaches have already proven their strong potentials in medicine. Despite that, applications in hematology are still scarce.
Aims: In this study we have developed novel ANFIS neuro-fuzzy prognostic models, based on clinical and morphometric diagnostic data, to enable better prediction of complete cytogenetic response (CCgR) for patients with chronic myeloid leukemia.
Methods: This prospective study included a consecutive series of patients with chronic myeloid leukemia (CML) who were started on imatinib therapy. Analysis was performed with CCgR at 6, 12, and 18 months as the outcome variables. A total of 40 patients on imatinib therapy were included in the final analysis. Of these, 25 (62.5%), 29 (72.5%), and 32 (80%), respectively, achieved CCgR at 6, 12, and 18 months after initiation of imatinib. Computationally intelligent neuro-fuzzy models that were developed included EUTOS score on diagnosis and one of the following morphometric parameters: microvascular density, length of the minor axis, area or circularity of the blood vessel. Adaptive neuro-fuzzy systems represent a specific combination of artificial neural networks and fuzzy logic, thus combining the learning ability of artificial neural networks with the knowledge representation capability of fuzzy logic systems. ANFIS (Adaptive Neuro Fuzzy Inference System) consists of five layers of nodes (neurons), each of which performs a particular function on incoming signals as well as a set of parameters pertaining to this node. The basic architecture of ANFIS using hybrid learning algorithm is presented in Figure 1.
Results: All analysed patients have received imatinib mesylate as their first-line therapy for CML. Model predictions (0–1) for any individual patient were interpreted as probability of CCgR at 6, 12 or 18 months. The overall accuracy of the final model was determined by comparing the predicted values with the actual events. A probability cut-off point of 0.50 (50%) was used to classify observations as events or non events, and patents were divided in training, validation and testing groups. Best performing ANFIS model, including EUTOS score and minor axis morphometric parameter was better than a model that includes only EUTOS score and regression model based on the same inputs. Overall model correct classification achieved for EUTOS, two input LR model and two input ANFIS model were respectively 75%, 75% and 77.5%, while areas under curve on ROC graphs were 0.776, 0.829 and 0.875 respectively.

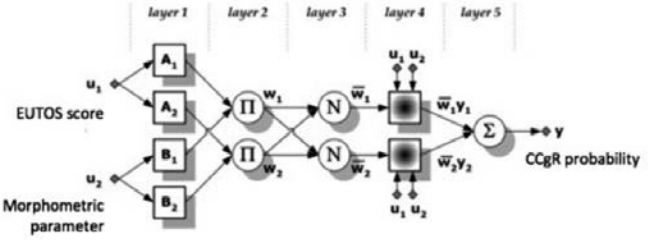

Figure 1.

Summary/Conclusions: The major finding of this study is that ANFIS models using the morphometric parameters, available at diagnosis of chronic phase of the CML, may improve prediction of CCgR at 6, 12 and 18 months on imatinib therapy, in comparison to the EUTOS score being the standard prognostic scoring system and regression models using the same inputs. Using neuro-fuzzy computationally intelligent ANFIS models with morphometric parameters in conjunction with EUTOS score improves prediction of CCgR. Validation on larger groups of patients is needed, but these findings indicate that neuro fuzzy models could aid in individual CML patient risk stratification.

A NATIONWIDE OBSERVATIONAL STUDY OF PONATINIB IN CHRONIC MYELOCYTIC LEUKEMIA OUTSIDE CLINICAL TRIALS

A. Shacham Abulafia[1,2,*], R. Ratzon[2], D. Lavie[3], Y. Volchek[4], R. Ram[2,5], I. Hellman[2,6], L. Shargian[7], A. Gourevietch[8], E. Chubar[9], M. Koren-Michowitz [2,10], I. zilbershats[11], P. Raanani[12], U. Rozovski[12]
[1]hemato-oncology, Rabin Medical Center, Petah Tikva, [2]Sackler School of Medicine , Tel Aviv University, Ramat-Aviv, [3]Department of Hematology , Hadassah-Hebrew University Medical Centre, Jerusalem, [4]Hematology Division , Chaim Sheba Medical Center, Tel-Hashomer, [5]Bone Marrow Transplantation Unit, Sourasky Medical Center, Tel Aviv, [6]Department of Hematology, Meir Medical Center, Kfar Saba, [7]Bone Marrow Transplantation Unit, Rabin Medical Center, Petah Tikva, [8]Hematology Institute , Soroka University Medical Center, Beer-Sheva, [9]Hematology unit, HaEmek Medical Center, Afula, [10]Department of hematology, Assaf Harofeh Medical Center, Zeriffin, [11]Department of hematology, Wolfson Medical Center, Holon, Israel

Background: In December 2014 the oral tyrosine kinase inhibitor (TKI), ponatinib was granted an accelerated approval by the FDA based on promising results from the phase II PACE (Ponatinib Ph-ALL and CML evaluation) trial. Yet, nowadays the use of this drug is limited because of safety issues, most notably increased risk of vascular complications. Currently, there is very little real-life information regarding the use of ponatinib outside clinical trials.
Aims: The purpose of the current study is to characterize patients who received ponatinib and to assess the safety profile and efficacy of ponatinib outside clinical trials.
Methods: Data from electronic charts of chronic myeloid leukemia (CML) patients treated with ponatinib were analyzed.
Results: *Patients characteristics*: Between 4.2011 and 1.2017 (69 months) 37 patients with an initial diagnosis of CML in 9 medical centers in Israel received ponatinib. The median age at time of treatment was 43 years (range: 9 to 82) and approximately half of the patients had chronic phase CML (N= 19, 53%). Based on their medical history, 36% (N=12) were at increased risk for vascular complications. *Pre-ponatinib treatments:* Patients received at least one other TKI and most received at-least two different TKI-

based regimens (N=28, 76%). Nine patients (25%) underwent hematopoietic stem cell transplantation (HSCT) prior to ponatinib. The time that lapsed from diagnosis until ponatinib initiation ranged considerably (from 1 to 215 months, median 47 months). *Indications for ponatinib switch:* 26% of patients (N=9) switched to ponatinib because T315I mutation was detected. The remaining switched either because of progressive disease, *i.e.* accelerated (N=5, 14%) or blastic (17%, N=6, 17%) phases, and 14 (39%) because they experienced loss of previous molecular or cytogenetics response. Only 5% (N=2) switched because of unacceptable side effects to previous treatments. *Treatment with Ponatinib:* Patients received ponatinib for a median time of 14 months (range: 1 to 51). The drug started at the recommended dose of 45 mg/day only in 60% (N=22) of patients and in 24% of them (N=9) the dose was reduced during treatment. The median survival time of patients with ponatinib was 38 months (95%CI: 30 to 47 months) (Figure 1). Patients died because of cerebrovascular event (N=1), sepsis (N=2) or graft *vs* host disease that developed shortly after HSCT. *Response assessment*: Response assessment was available for 32 patients (86%). Seventy percent (N=22) achieved molecular response, of which 60% (N=13) achieved at least major molecular response. The median time to maximal response was 7 months (range: 3 to 28 months). *Drug discontinuation:* Twenty four percent (N=9) discontinued ponatinib after a median of 7 months (range: 1 to 18 months) because of disease progression (N=6) or severe adverse effects in two patients (cerebrovascular event and severe pancytopenia).

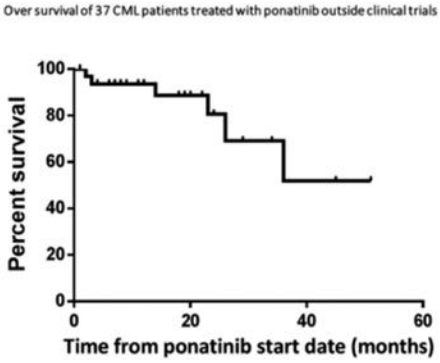

Figure 1.

Summary/Conclusions: In our cohort ponatinib was almost always used in patients who experienced treatment failure to previous TKIs. Still, molecular response was achieved in most patients, even in those with progressive disease in accelerated or blastic phases. The vast majority of patients received reduced doses of ponatinib and although more than one third of patients were at-risk for vascular events, only two patients developed serious life-threatening vascular episodes. In heavily pre-treated patients, ponatinib is effective and safe and can be considered even in patients with cardiovascular risk factors.

PB1828

MOLECULAR RESPONSE TO THERAPY WITH TYROSINE KINASE INHIBITORS IN PATIENTS WITH BCR-ABL1(+) CHRONIC MYELOID LEUKEMIA PRESENTING WITH AN ISOLATED THROMBOCYTOSIS AT THE ONSET

G. Balatzenko[1,*], V. Hrischev[2], K. Ignatova[2], Z. Stoyanova[2], A. Lilova[2], S. Angelova[1], S. Ivanova[1], M. Romanova[1], I. Ivanova[1], G. Tsvetkova[3], E. Hadjiev[3], V. Madzharova[2], T. Dikov[2], B. Spassov[2], Y. Davidkova[2], M. Jagurinoski[2], M. Guenova[2]
[1]Laboratory of Cytogenetics and Molecular Biology, [2]National Specialised Hospital for Active Treatment of Hematological Diseases, [3]Alexandrovska University Hospital, Sofia, Bulgaria

Background: Generally, chronic myeloid leukemia (CML) and essential thrombocythemia (ET) are characterized by distinctive clinical and laboratory characteristics, including the spectrum of genetic abnormalities - Philadelphia chromosome (Ph) and *BCR-ABL1* fusion transcripts in CML and *JAK2, CALR* or *MPL* gene mutations in ET. Therefore, even in the presence of overlapping features in some cases, the correct diagnosis can be assigned. However, in rare cases Ph chromosome and *BCR-ABL1* fusion transcripts can be found in otherwise typical ET. Due to the low number of reported cases the subsequent course of the disease and the response to tyrosine kinase inhibitors (TKI) in such patients with *BCR-ABL1*-positive thrombocytosis is largely unknown.
Aims: To report the clinical course and response to TKI in patients (pts) with CML presenting with isolated thrombocytosis at the onset.
Methods: In total, 31 pts with Ph(+) and/or *BCR-ABL1*(+) isolated thrombocytosis and a moderate or absent leukocytosis were retrieved from the hospital database. The cohort comprised 17 females and 14 males, at a median age of 47 years (range 23-86). Diagnosis was based on blood and bone marrow morphology and differential, cytogenetics and/or molecular testing according to the WHO criteria (2008). Molecular monitoring was carried out using Xpert BCR-ABL Monitor or Xpert BCR-ABL Ultra tests (Cepheid). In total, follow up data for at least 6 months (mean 65 months) are available for 25 patients treated with TKI as a first-line therapy.
Results: At diagnosis the median leukocyte count was 22 x10^9/l (range 6-36) and platelet count – 1316x10^9/l (range 770-2815). Splenomegaly was found in 5 pts (16.1%). Only one patient was diagnosed in accelerated phase as the remaining presented in chronic phase at diagnosis. Interestingly, 4 pts (12.9%) had a history of an antecedent solid tumor. All patients enrolled in the study were *BCR-ABL1*(+): b3a2 (n=16) or b2a2 (n=15). Karyotypes were available in 23 pts and classical Ph was found in 16 of them (69.6%), while in 5 pts (21.7%) a cryptic translocation was detected as well as a variant Ph in the remaining 2 pts (8.7%). Imatinib was used as a first line therapy in 15 pts and optimal response was achieved in 53.3% (n=8), while 5 were switched to a second line, and 2 - to a third line therapy. First-line treatment with Nilotinib in 10 patients resulted in optimal response in 80% (n=8). In total, major molecular response (MR) was achieved in 80% (n=20), including deep MR in 56% (n=14). One pt was lost of follow up after optimal response was registered. No response was documented in 4 pts (16%) and progression to blast crisis developed in 2 of them. The mean OS was estimated 143 months and the cumulative proportion surviving at 5 years was 91%.
Summary/Conclusions: Interestingly, CML presenting with isolated thrombocytosis at diagnosis in our cohort had high proportion of antecedent malignancies and high incidence of cryptic Ph translocation without any specific correlation with the transcript types. However, the clinical course and molecular response to TKI therapy was similar to the reported in CML in general.
Ackowledgements: Partial support by the National Science Fund.

PB1829

BCR-ABL1 MOLECULAR RESPONSES AT 12-18 MONTHS USING THE QUANTIDEX QPCR BCR-ABL1 IS KIT PREDICT LONG-TERM EVENT-FREE SURVIVAL IN PATIENTS WITH TKI-TREATED CML

J. Brown[1,*], A. Ruskin[1], I. Beldorth[1], M. Fahey[1]
[1]Asuragen, Austin, United States

Background: Detection of BCR-ABL1 e13a2 or e14a2 transcripts (major breakpoint, M-BCR) of translocation t(9;22) (also known as the Philadelphia chromosome) is important in CML monitoring tumor burden. The International Scale (IS) was established to standardize reporting relative to a common baseline. As newer TKI therapies create deeper responses, analytical sensitivity has become a critical topic in investigations into TKI discontinuation, where researchers require a clinically validated assay that calls a molecular reduction (MR) of ≥4.5 logs below baseline (*i.e.* MR4.5 or 0.0032%IS).
Aims: To clinically validate the QuantideX qPCR BCR-ABL1 IS Kit and to reaffirm the clinical utility of BCR-ABL1 RT-qPCR monitoring in patients with t(9;22) positive CML, a correlation between molecular response (MR) values and long-term outcome was determined.
Methods: The QuantideX qPCR BCR-ABL IS Kit uses standard TaqMan chemistry to quantitate BCR-ABL1 and the ABL1 reference gene. Associated software reports an international scale BCR-ABL1 value and a log-transformed MR value, with a 3 log-reduction from pre-treatment baseline represented as 0.1%IS or MR3.0. Three laboratories performed BCR-ABL1 testing on banked RNA specimens from 96 chronic phase CML patients from 2 hospitals drawn 12-18 months after starting TKI therapy. Clinical events (TKI therapy change, loss of complete hematologic or cytogenetic response, progression to accelerated phase or blast crisis, kinase domain mutation, or death) were recorded through 36±4 months after starting TKI. Two operators per site also tested serially-diluted reproducibility samples (range MR1.0 to MR4.0) in multiple replicates over 5 days. The 95% LOD for the assay was defined as the median measured%IS value of 4 analogous serially-diluted specimens.
Results: 51 patients had MR<3.0 at 12-18 months post-TKI. Of these 51 patients who did not achieve a major molecular response (MMR), 20 had a subsequent clinical event, 17 had no event, and 14 were lost to follow-up (LFU). 45 patients had MR≥3 at 12-18 months post-TKI. Of these 45 patients who did achieve MMR, 8 had an event, 28 had no event, and 9 were LFU. Kaplan-Meier survival curves demonstrated a 22% prolongation of event-free survival (95% CI 2%>42%) at 3 years between the two MR groups [p=0.028; 58% (95% CI 44%>75%) for MR<3 *vs* 80% (95% CI 68%>93%) for MR≥3)]. Specimens with MR values ranging from MR1 to MR4 showed an average%CV of 2.6%. Day to day agreement was high with MR SD by operator ranging from 0.000 to 0.060. Site to site agreement was high with MR SD by site ranging from 0.000 to 0.069. The 95% LOD for both transcripts (e13a2 & e14a2) was MR4.7 (0.002%IS), allowing sensitive detection of the MR4.5 cutoff that defines "complete molecular response" in ongoing treatment-free remission clinical trials.
Summary/Conclusions: The QuantideX qPCR BCR-ABL IS Kit has excellent reproducibility and analytical sensitivity, and the achievement of MR≥3 (major molecular response) by this assay predicts prolonged event-free survival in TKI-treated CML patients.

PB1830

SHOULD SWITCHING TO SECOND GENERATION TKIS BE A RULE IN PATIENTS WITH CP-CML AFTER 3-6 MONTHS OF IMATINIB TREATMENT: RETROSPECTIVE ANALYSIS OF CML PATIENTS TREATED IN A SINGLE BRAZILIAN CANCER CENTER

A.P.S. Ferreira[1,*], F.S. Seguro[1,2], A.B. Medina[2], A.N.R. Abdo[2], F.V.R. Maciel[2], L.Y. Okada[1], I. Bendit[1]
[1]Hematology, Hospital das Clinicas da Faculdade de Medicina da USP, [2]Hematology, Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil

Background: Early molecular response is an important predictor for survival and therapy-free remission in chronic myeloid leukemia (CML). The current guidelines define BCR-ABL1 >10% at 3 months and/or 1-10% at 6 months as warning signs; however, it is not clear if switching imatinib to second generation TKIs in this scenario improves responses and overall survival in patients outside clinical trials.
Aims: To analyze the proportion of patients with major molecular response (MMR) at 12 months according to the molecular response at 3 and 6 months in a cohort of CML population, not enrolled in clinical trials and treated only with imatinib. Also evaluate the incidence of molecular responses log3.0, log4.0 and log4.5 at any time in patients who did not switch to second generation TKIs.
Methods: Retrospective analysis of all 226 patients diagnosed with CML from January 2007 until January 2015 in our hospital. The exclusions criterias were: advanced phases, inclusion in clinical trial, treatment with second-generation TKI in the first 12 months (due to toxicity or failure). The molecular response was evaluated according ELN recommendations: RQ-PCR assessment of BCR-ABL1 levels every 3 months until achievement of MMR, with molecular evaluation every 3-6 months afterward. All samples were analyzed in the same laboratory which was standardized since 2007.
Results: In the first cohort, 150 patients with CML chronic phase were analyzed. Optimal molecular responses by the ELN at 3 and 6 months were predictors of MMR by 12 months (94% *vs* 6%, p<0.0001 at 3m, 89.3% *vs* 10.7%, p<0.0001 at 6m), but there was no overall survival benefit. A second cohort with 119 patients received only imatinib, with a medium follow-up time of 71 months (13-117m). MMR was achieved by 60% of this imatinib-only group after 12 months and by more than 90% after 36 months (Figure 1). Patients with BCR-ABL1 <10% at 3 months and/or <1% had a higher probability of achieving MMR3, MMR4 and MMR4.5 at any time.

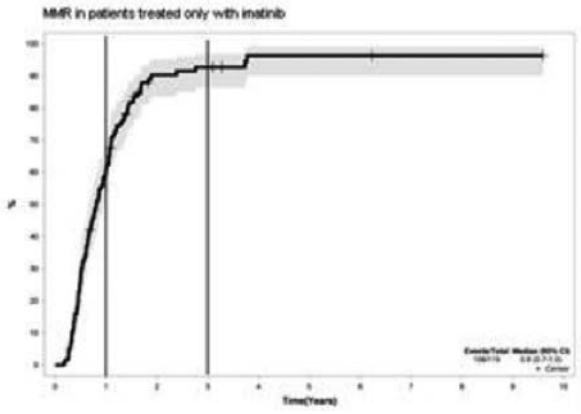

Figure 1.

Summary/Conclusions: Our study shows that around 30% of the patients that do not fail to imatinib at the first year of treatment may be late responders. Not all patients should change therapy, if they have not reached MMR at 12 months. Molecular response at 3 at 6 months might guide the decision to switch TKI, but patient's comorbities, possibility of discontinuation and cost of therapy should also be considered.

PB1831

PREDICTIVE PARAMETERS FOR IMATINIB FAILURE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

D. Lekovic[1,2,*], M. Gotic[1,2], B. Zivojinovic[1], N. Milic[3], J. Jovanovic[1], N. Colovic[1,2], J. Bodrozic[1], V. Milosevic[1], A. Bogdanovic[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Medical Faculty, [3]Institute for Medical Statistics, University of Belgrade, Belgrade, Serbia

Background: Development of tyrosine kinase inhibitors (TKI) has significantly changed natural course of chronic myeloid leukemia (CML) and increased 10 year overall survival from 10-20% to 80-90%. Until recently, imatinib was the standard first-line treatment in CML. In 2013, nilotinib and dasatinib were approved as alternative front-line options. However, none of three TKI has been shown to have a clear survival advantage so this raised a debate on treatment selection. The early identification of patients expecting poor outcome is crucial for offering an alternative TKI regimen.
Aims: to analyze predictive parameters for Imatinib response as first-line treatment of CML patients.
Methods: The study was conducted on 168 consecutive patients with chronic phase of Ph+ CML who were diagnosed and treated at single university hospital from December 2000-January 2015. Following data were analyzed in terms of treatment response to Imatinib: demographic characteristics; currently used prognostic scores (Sokal, Hasford, EUTOS); liver and spleen size; laboratory parameters; influence of comorbidities analyzed by three scores (ACE 27, HCI-CI, SCIRS); occurrence of second malignancies; conventional cytogenetic results; therapy, duration of therapy, cytogenetic responses, overall survival (OS) and outcome.
Results: The mean age at diagnosis was 48±14.4 years (range: 18-74) with 87.5% of patients<65 years. The OS at 5 and 10 years was 97% and 91% respectively. Overall response to Imatinib treatment was as the follows: 131 patients (78%) achieved CCyR, 14 patients (8.3%) majorCyR, 4 patients (2.4%) minorCyR, 16 patients (9.5%) had no cytogenetic response, 2 patients (1.2%) had hepatic toxicity verified by liver biopsy in the first six months of Imatinib treatment and 1 patient (0.6%) was lost from follow-up. After achievement of CCyR, 25 patients (19%) had a progression of disease by losing CCyR or development of AP/BP. Median time to progression was 24 months (range 12-102). After the median follow up of 87 months in 61 patients (36.3%), the Imatinib failure was verified. All three prognostic scores (Sokal, Hasford, EUTOS), age, gender, hemoglobin level, leukocyte and platelet count, splenomegaly, eosinophils and basophils in peripheral blood were not found to be statistically significant for the Imatinib failure. Cox regression analysis identified hepatomegaly (p=0.001), leukocytosis≥100x109/L (p=0.001), blood blasts≥1% (p=0.002) and presence of additional cytogenetic aberrations (ACAs) (p=0.002) as a predictors of Imatinib failure. Accordingly, we assigned risk scores based on hazard ratios (HR) to hepatomegaly (HR=4.089; 2 points), leukocytosis ≥100x10^9/L (HR=3.158; 1 point), blasts in peripheral blood ≥1% (HR=2.912; 1 point), and presence of ACAs (HR=11.110; 2 points). A final 3-tiered prognostic model named IMA-FAIL was thus developed, as low (score 0), intermediate (score 1-3), and high risk (score ≥4), according to which imatinib failure had 17% (8/47) of patients in low, 34.9% (30/86) in intermediate and 76.7% (23/30) in high risk group (HR=3.973, 95% CI for HR 2.237-7.053, *p* <0.001). In addition, presence of comorbidities as well occurrence of second malignancy were not predictors for Imatinib failure.
Summary/Conclusions: Hematologists are facing with challenge of making decision which TKI to choose upfront with increasing a chance to achieve best possible response. The new score allows better selection of patients who are suitable for treatment with Imatinib and may guideline the clinical decision for front-line treatment of CML.

PB1832

A MULTICENTRE AUDIT OF SYMPTOMS AND QUALITY OF LIFE IN IRISH CML PATIENTS ON TYROSINE KINASE INHIBITORS

J. Garry[1,*], P. Murphy[1], J. Quinn[1], P. Thornton[12], J. Sargent[3], M. McCloy[4], A. Fortune[5], M. Fay[5], N. Herlihyn[5], D. Angelov[5], K. Fadalla[6], C. Cotter[6]
[1]Haematology, Beaumont Hospital, [2]Haematology, James Connolly Memorial Hospital, Dublin, [3]Our Lady of Lourdes Hospital, Drogheda, Ireland, [4]Haematology, Our Lady Of Lourdes Hospital, Drogheda, [5]Haematology, Mater Misericordiae University Hospital, [6]Haematology, St. Vincents University Hospital, Dublin, Ireland

Background: The development of tyrosine kinase inhibitors (TKIs) over the last 20 years has dramatically improved the outcomes for patients with every stage of chronic myeloid leukaemia (CML). Since the approval of the first TKI, imatinib, in 2001, there are now currently 5 oral TKIs available. Three are approved for frontline use (imatinib, dasatinib and nilotinib) and 2 others (bosutinib and ponatinib) approved for intolerance or failure of prior TKI. Because CML patients need to continue TKI treatment indefinitely, it is necessary to consider not only differences in potency and progression-free survival, but also TKI induced toxicity and quality of life (QOL) when choosing a TKI.
Aims: The aim of this audit was to determine the impact of TKIs on symptom burden and QOL in patients with CML across multiple centres in Ireland, using the MD Anderson Symptom Inventory (MDASI) tool.
Methods: Across 7 centres in Ireland, a total of 87 CML patients currently on TKIs were identified. The mean age was 60yrs with an equal sex distribution (44 male, 43 female). All of these patients were in chronic phase. 79% of patients were in MMR (major molecular remission) at the time of survey. 53 patients were on imatinib, 19 patients on nilotinib, 13 on dasatinib and 2 on bosutinib. Patients from the 7 centres were surveyed at varying time periods between July 2015 and Feb 2017. Patients were contacted by phone. Symptom burden and QOL were assessed using the MD Anderson Symptom Inventory, an extensively validated tool which includes 13 core and 7 CML-specific symptoms, as well as 6 interference items. The questionnaire took on average 5mins to complete and asked patients to rate their symptoms on a scale of 1-10 as experienced over the preceding 24 hours.

Results: Of the 87 patients surveyed, the most commonly prevailing symptoms were fatigue (72.4%), peripheral oedema (48.3%), disturbed sleep (46%), myalgia (43.7%) and dry mouth (39.1%).The least common symptoms were nausea (20.7%) and vomiting (6.9%). Almost half (49.4%) of patients reported at least 1 severe side effect (a score of 7 or more). The most severe side effects were drowsiness (mean score 6.3), myalgia (mean score 6), fatigue, nausea and vomiting (mean score 5.7 each). There was no significant difference in symptom prevalence or severity among the different TKIs. As regards the perceived interference of symptoms on daily functioning, only 29% reported a score of 7 or more in at least 1 of the 6 interference items (*i.e.* general activity, mood, work, relations with others, walking and enjoyment of life), and only 14% reported that their enjoyment of life was severely affected (score of 7 or more). Of note, exactly two thirds of patients reported little or no interference with their enjoyment of life (score of 0-3).
Summary/Conclusions: As demonstrated in this audit, patients with CML on TKIs frequently experience chronic adverse events. Interestingly, CML patients taking second generation TKIs did not appear to have any difference in frequency or severity of symptoms or in QOL compared to patients on imatinib. Despite excellent survival results obtained with TKIs since 2001, an emphasis needs to be placed on symptom burden and QOL. The potential for adverse events with long term therapy may result in dose adjustments, treatment discontinuation, or nonadherence, all of which may negatively affect treatment efficacy. Therefore, assessment of QOL and the symptom burden experienced by patients with CML is useful to facilitate individual treatment decisions and to improve outcome as well as to evaluate the efficacy of emerging therapies.

PB1833

COST-EFFECTIVENESS OF A THERAPEUTIC EDUCATION PROGRAM (TPE) FOR PATIENTS WITH CHRONIC MYELOID LEUKEMIA AND TREATED BY TYROSINE KINASE INHIBITORS

M. Artur-Cordier[1,*], A. Chan Hew Wai[2], L. Cochard[3], M.-L. Fontoura[4], V. Blazejewski[4], P. Lenain[4], R. Varin[5], F. Basuyau[1], M. Daouphars[1]
[1]Pharmacy, Centre Henri Becquerel, ROUEN, [2]Pharmacy, Hopital Saint Louis, PARIS, [3]Pharmacy, CHU de Caen, CAEN, [4]Hématology, Centre Henri Becquerel, [5]Pharmacy, CHU de Rouen, ROUEN, France

Aims: Within our cancer centre, an TPE program on ITK in the management of CML has been authorized since 2011. We conducted a pharmacoeconomic study to evaluate the TPE clinical impact on responses to TKI in patients with CML (based on recommendations from European Leukemia Net) and also the costs in terms of use of care.
Methods: Over the 12-month follow-up period, the study population consisted of 2 groups of CML patients monitored in our centre: - Intervention group (n=18) (IG) : Patients who benefited of TPE sessions on TKI between January 2013 and August 2015 - "Matched controls" group (n=18) (CG): Patients who benefited only from the usual care, matched to the "Intervention" group. The method of pairing the 2 groups of patients according to the age at diagnosis, sex, the molecule used in first line and the prognostic risk according to the score of Sokal was used. The main criterion of efficacy was the MMR. The considered costs were: the cost of the TPE program, estimated on the basis of the French health insurance reimbursement per patient and the costs associated with the use of "supplementary" care (examinations, consultations and additional hospitalizations). The point of view was from French health insurance.
Results: Over the 12-month follow-up period, the number of patients in MMR was similar between the 2 groups (9 in IG *versus* 8 in CG). However, the average time to obtain the MMR was significantly shorter in IG (6.9 months±3.8) than in CG (11.3 months±2.1) ($p < 0.05$). The mean duration of MMR maintenance over the 12-month follow-up period was significantly longer in IG (3.2 months±3.5) than in CG (1.5 months±1.9) ($p < 0.05$). Regarding the use of additional care, unexpected hospitalizations were significantly more numerous in CG than in IG (4 *versus* 0). Thus, costs associated with use of additional care were significantly lower in IG (€ 3,566) than in CG (€ 12,709). Thus, € 250 invested (annual allowance per patient) in the TPE saves € 508 in the use of care and reduces the time required to obtain a MMR by 4.4 months.
Summary/Conclusions: Thus, TPE is clinically and economically beneficial in our study population. By increasing the patient capacity to adapt to the treatment through the development of skills and adaptation processes, TPE reduces the costs of seeking care while improving the clinical response to treatment with a faster and more sustainable major molecular response.

PB1834

ROLE OF ALLO-HSCT IN THE TREATMENT OF PATIENTS WITH T315I MUTATION IN THE TKI ERA

J. Vlasova[1,*], E. Morozova[1], O. Shukhov[2], M. Barabanshchikova[1], T. Gindina[1], I. Barhatov[1], I. Martynkevich[3], V. Shuvaev[3], A. Turkina[2], B. Afanasyev[1]
[1]R.M. Gorbacheva Institute of Pediatric Oncology Hematology and Transplantation St. Petersburg State Medical I. Pavlov University., St.Petersburg, [2]National research center for hematology of ministry of healthcare,Russian Federation, Moscow, [3]Russian Research Institute of Hematology and Transfusiology, St.Petersburg, Russian Federation

Background: Resistance to tyrosine kinase inhibitors (TKI) in patients with chronic myeloid leukemia (CML) is frequently caused by point mutations in the BCR-ABL kinase domain, including the gatekeeper mutant T315I, which confers a high degree of resistance to all currently approved tyrosine kinase inhibitors except ponatinib. The role of allo-HSCT in such patients is still disputable.
Aims: To evaluate the results of different treatment modalities in CML patients with T315I mutation.
Methods: Retrospective analysis of 53 BCR-ABL^{T315I} –positive CML patients (pts) was done.
Allogeneic bone marrow transplantation (allo-HSCT) was made in 16 pts, 37 pts received only pharmacological therapy (21 pts received TKI as monotherapy or in combination with other drugs other 16 pts received hydroxyurea, interferon- α or chemotherapy). At the time of T315I detection 29 (55%) pts were in CP, 19 (36%) pts had AP and 5 (9%) pts were in BC. Median (Me) age at the time of mutation detected was 47 years (15-76) (38 years in HSCT-group). 2 pts were in BC at the time of HSCT, 5 pts were in AP, 7 pts were in CP≥2. The number of points on EBMT scale: 3-4 points – 12(75%) pts, 5-7 points – 4(25%) pts. 11 (69%) pts received more than 2 lines TKIs before HSCT .In allo-HSCT group 11 (69%) pts had unrelated donors. Conditioning regimen in 13 (81%) pts had reduced intensity, in 3(19%) pts had MAC. Me time to HSCT after T315I detection was 10 months (1-38). Mutation analysis was performed by Sanger sequencing. Overall survival (OS) was estimated by Kaplan-Meier method with log-rank test for comparison between groups. Cox regression was used for multivariate survival analysis that included next covariates: age, phase on the time of mutation detection, performance of allo-HSCT, time to T315I detection from TKI start.
Results: Me follow-up time after T315I detection was 21 months (1-100). 5-years OS in whole group was 42% (Figure 1A). According to multivariate analysis only CML phase at the time of mutation detection significantly affect to survival in whole group. All pts in BC (n=5, 2 in HSCT group and 3 in non-HSCT group) died within first year after T315I indication wherein Me survival time was 1,3 month (Figure 1B). 5-years OS in non-HSCT group (n=37) was 42% with Me survival time 2,8 years. 5-years OS after allo-HSCT (n=16) was 37% with Me survival time 5 months (Figure 1C). All living patients after allo-HSCT are in deep molecular response. There was no significant difference in 5-years OS between TKI (n=21) and non-TKI (n=16) pharmacological therapy (non-HSCT) groups (42% and 47% respectively, p=0,53) (Figure 1D).

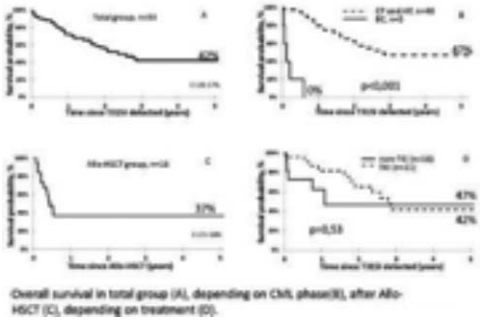

Figure 1.

Summary/Conclusions: Detection of T315I mutation in TKI-resistant patients is extremely unfavorable factor for survival, especially in the advanced phase CML, and it is a great reason for switching to ponatinib or other new potential investigated drugs if possible. Allo-HSCT can be a potential option for this group of patients in case of good selection taking into consideration transplant risk, especially for patients in CP ≥2.

PB1835

THYROID FUNCTIONAL STATUS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA ON TKIS - SINGLE -CENTER RESULTS

M. Dragičević[1,2,*], I. Urošević[1,2], M. Dokić[1,2], I. Bajkin[2,3], T. Ičin[2,3], I. Perčić[1,2], A. El Farra[1,2]
[1]Clinic for Hematology, [2]Faculty of Medicine, University of Novi Sad, [3]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Novi Sad, Serbia

Background: Tyrosine kinas inhibitors (TKI) as target specific compounds profoundly changed the outcome in patients with chronic myeloid leukemia (CML). TKI-induced thyroid dysfunction is now recognized as a common toxicity associated with some TKI. In the previous decade, cases of thyroid dysfunction have been reported in patients treated with different TKIs.
Aims: To evaluate the thyroid functional status in CML patients treated with imatinib and nilotinib.

Methods: This cross-sectional study comprised 85 patients with CML in chronic phase, treated with imatinib and nilotinib, at the Clinic for Hematology, Clinical Centre of Vojvodina, Serbia. Thyroid function was assessed by analyzing the serum FT3, FT4 and TSH levels. Hypothyroidism in relation with TKI therapy was defined as newly diagnosed hypothyroidism (while the patient was already on TKI therapy) requiring hormone substitution therapy or serum fT4 level <11,5 pmol/l and TSH >5.50 mIU/l. Patients with previous medical history of thyroid dysfunction were excluded. The duration of TKI treatment varied from 2 month to 10 years. The dose of imatinib was 400mg daily, while nilotinib was dosed 800mg a day.
Results: From the total number of patients included, 37 (43,53%) were female and 48 (56,47%) were male. Mean age was 56,71 age (range 21-84). The prevalence of hypothyroidism (clinical, and subclinical) was 8,23% (n=7) which is in accordance with the prevalence in general population. Three patients (3,53%) were diagnosed to have subclinical hypothyroidism (defined as normal serum fT4 and TSH >5.50 mIU/l). Hypothyroidism was more common in males (71,5%, p= 0,29, not statically significant). In patients treated with imatinib, 2 (3,4%) had subclinical, while 3 (5,01%) had clinical hypothyroidism. Of the 26 patients treated with nilotinib, subclinical hypothyroidism was detected in 1 (3,85%), as well as clinical hypothyroidism (3,85%). Other thyroid dysfunctions were not detected.
Summary/Conclusions: Hypothyroidism was the only thyroid dysfunction in our cross-sectional study. The prevalence of hypothyroidism in our study group did not differ from general population. Additional study on a larger sample size and evaluation of antibodies is required.

PB1836

RESPONSE RATES AND SURVIVAL OF PATIENTS WITH CHRONIC MYELOID LEUKAEMIA INITIALLY TREATED WITH IMATINIB: 11 YEAR EXPERIENCE OF A TEACHING HOSPITAL

M. Ruparelia[1,*], P. George[1], D. Brownings[1], K. Marshall[1], A. Hunter[1], M. Martin[1], K. Hodgson[1]
[1]University Hospitals Leicester, Leicester, United Kingdom

Background: In large trials, patients with chronic myeloid leukaemia (CML) treated with Tyrosine Kinase Inhibitors (TKIs) have relative survival rates of up to 90% that of age-matched controls. Patients achieving complete cytogenetic responses (CCyR) within 2 years of starting Imatinib have survival rates equivalent to the general population. Newer TKIs are associated with faster and deeper treatment responses, but have a more toxic side effect profile as well as being more costly.
Aims: This study looks at the 11 year experience of a single teaching hospital treating a population of almost one million and presents the response and survival data of this unselected population of patients with CML treated with imatinib as initial therapy.
Methods: A retrospective case record review was undertaken on CML patients identified from the regional cytogenetics department. Imatinib was available for routine prescription in the UK from 2003, so a 11-year period from 2003 to 2013 was selected to allow for adequate follow-up.
Results: In total 83 patients were newly diagnosed in this time period. Four patients, treated on SPIRIT2 with dasatinib as initial therapy, have been excluded from the subsequent analysis, leaving 79 patients treated initially with imatinib 400mg daily. The median age at diagnosis was 53 years (range 13-93) with 40 female and 39 male patients. The median follow up was 75 months (range in living patients 29-163 months). Fifteen patients have died (19%). The median age at diagnosis of these was 73 years. Two deaths were transplant-related, both in patients who had failed available TKIs and had mismatched transplants. The only treated patient who died of accelerated disease was intolerant of all TKIs and unfit for transplant. Three patients died of other malignancies (ovarian, bowel and melanoma). Seven patients were transplanted. Of the surviving 5, 2 had sibling transplants early in the TKI era, 2 had MUD transplants after failing imatinib prior to the availability of second line drugs, and one failed to make an adequate response to imatinib then nilotinib and received a sibling transplant. All surviving transplant patients are in a major molecular response (BCRABL:ABL ratio <0.01, MMR). An MMR was achieved by 60/79 (76%) patients. Of the 19 without MMR, 1 is lost to follow-up, and 9 have died, of which only one death was due to accelerated CML in a patient intolerant of all TKIs. Of those 9 patients living not in MMR, 8 have a CCyR. Three are elderly patients in whom we have taken a pragmatic approach, three are related to patient compliance, two to treatment limited by severe side effects and one had TKI interruption to facilitate cancer treatment. Of the sixty patients in MMR, 40 achieved this on standard dose imatinib. Four patients required increased dose of imatinib, 11 were switched to second line TKI and 5 were transplanted. A complete molecular response (BCRABL:ABL ratio <0.000, CMR) was achieved by 10 patients, six on standard dose imatinib.
Summary/Conclusions: This data shows the real life experience of patients treated for CML in the TKI era. At six years follow up, the overall survival was 86% which is remarkably similar to that of the IRIS trial patients. Using an intention to treat analysis in this unselected population, up front imatinib with appropriate escalation of treatment where response is unsatisfactory achieves an MMR rate of 76%. This offers reassurance that where appropriate monitoring is feasible, imatinib remains a good first choice for patients presenting with CML.

PB1837

FRONT-LINE NILOTINIB IS A BETTER CHOICE THAN FRONT-LINE IMATINIB FOR CML PATIENTS WITH DELAYED TREATMENT: 11 YEAR FOLLOW-UP

A. Kurtovic-Kozaric[1,*], E. Islamagic[2], S. Kurtovic[3], A. Hasic[4], V. Bijedic[3], F. Colakovic[5], N. Skobic Bovan[6]
[1]Clinical pathology, cytology, and human genetics, Clinical Center of the University of Sarajevo, [2]Faculty of Natural Sciences, University of Sarajevo, [3]Hematology, Clinical Center of the University of Sarajevo, [4]Genetics, University of Sarajevo, [5]Hematology, Clinical Center Zenica, Sarajevo, [6]Hematology, University Clinical Hospital Mostar, Mostar, Bosnia and Herzegovina

Background: CML patients in developing world had to wait for the start of TKI treatment, from several months to years. The significant delay in proper treatment with imatinib has had drastic consequences on patient outcomes including survival, CCyR and MMR. Nilotinib was introduced in 2011 as front- and second-line therapy for newly diagnosed as well as patients who waited for TKI treatment for a long time.
Aims: In this study we compared the long-term real life clinical outcomes (OS, CCyR and MMR) of patients receiving front- line imatinib and front-line nilotinib therapy in Bosnia and Herzegovina in the period from 08/2005 to 08/2016, categorized based on delayed start of therapy.
Methods: All newly diagnosed CML patients in CML-CP (n=149) who started their TKI treatment in period from August 2005 to August 2016 were included in this multicentre retrospective cohort study. Patients were categorized as: Group 1 (n=118) consisted of patients who started with front-line imatinib (300 mg, 400 mg or 600 mg twice daily; Glivec or generic imatinib therapy) and Group 2 (n=31) contained patients receiving front-line nilotinib (300 mg twice daily). Patients on imatinib were further categorized by the duration of treatment delay into three subgroups (<5 months, 6-13 months and >13 months) and patients on nilotinib therapy were divided into two subgroups (patients who waited less and more than 6 months on the start of therapy). Nilotinib became available as front or second-line therapy in March 2011. Standard patients' variables were collected and disease progression was established as loss of CCyR and MMR. Survival probabilities were estimated with the Kaplan-Meier method and compared using the log-rank test.
Results: We analyzed 149 patients (median age was 54.5 years; 57% was males) in chronic phase of CML. The median follow-up from time of diagnosis and start of therapy was 45 months and 39 months, respectively (range 3-145 months). Median wait period for therapy in patients who waited less and more than 6 months was 0 months (range 0-6) *vs* 15 months in the waiting group (range 9-63). At 11 years, overall survival for patients on front-line imatinib (Group 1) and front-line nilotinib (Group 2) was 83% and 87%, respectively. According to ITT principle, achievement of CCyR and MMR at 24 months was higher in Group 2 compared to Group 1 (81% *vs* 66% and 74% *vs* 37%, respectively). Rate of death was similar in both studied groups (20/118 *vs* 4/31). When we analysed delayed treatment at 24 months, CCyR for patients who received therapy immediately, who waited 6-13 months and more than 13 months, was 74% *vs* 64% *vs* 40%, respectively. Regarding nilotinib treatment at 24 months, patients on 1st line immediate nilotinib *vs* 1st line delayed nilotinib achieved 83% *vs* 77% for CCyR and 78% *vs* 69% for MMR, respectively.
Summary/Conclusions: Our results after 11 years of follow up suggest that nilotinib demonstrated improved efficacy over imatinib therapy. Achievement of CCyR and MMR at 24 months was higher in patients on front-line nilotinib therapy. Patients who waited for therapy had optimal response regardless the wait period on nilotinib therapy.

PB1838

THE INFLUENCE OF AGE ON TREATMENT OUTCOME OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA RECEIVING FRONTLINE IMATINIB

I. Cojbasic[1,2,*], L. Macukanovic Golubovic[1,2], M. Vucic[1,2], N. Govedarovic[1,2]
[1]Medical Faculty, University of Nis, [2]Clinic of Hematology and Clinical Immunology, Clinical Center Nis, Serbia, Nis, Serbia

Background: The tyrosine kinase inhibitor (TKI) imatinib was the first targeted therapy for patients with chronic-phase chronic myeloid leukemia (CP-CML), and its introduction was associated with substantial improvements in response and survival compared to previous therapies. Earlier studies have indicated that the effect of age at diagnosis of CP-CML was minimized in patients treated with imatinib: fewer responses but the same outcome for older patients. However, recently published results from clinical controlled trials indicated that there were differences in clinical outcome depending on age at diagnosis of CP-CML.
Aims: The aim of this study was to evaluate impact of age on the treatment outcome in patients with chronic myeloid leukemia treated with frontline imatinib.
Methods: A newly diagnosed CP-CML patients treated and followed in our institution were surveyed retrospectively from August 2006 to August 2016. According to age, cohort was divided into three groups: young adults (18-45 years) (YA), middle aged adults (46-64 years) (MA) and elderly persons (65 and more years) (EP). Patients' demographics, disease risk scores, duration of imatinib therapy and follow-up, cytogenetic and molecular responses,

adverse event (AEs), the 5-year event-free survival (EFS) and 5-year overall survival (OS) were all evaluated. Clinical features of the patients in different age groups are summarized in Table 1.

Results: The patient cohort consisted of 94 patients with median age of 53.4 years (range 18-78), with a slight predominance of females of 53.2%. There were more patients with intermediate and high Sokal scores in the EP group than in the groups MA and YA (p<0.001). To the contrary of that, most patients with high EUTOS score were observed in the group YA compared to MA and EP groups (p<0.001). The three groups were balanced regarding Euro score. The median duration of imatinib therapy was the longest in MA group (61.4 months *vs* 40.6 months in YA and 38.2 months in EP patients p<0.001). Furthermore, median follow-up duration was also the longest in MA group (64.3 months *vs* 48.5 months in YA and 44.7 months in EP patients p<0.001). The rates of complete cytogenetic response (CCyR) were similar in all three analysed groups (80.6% in YA, 86.5% in MA and 75.9% in EP, p=0.328) while rate of major molecular response was the highest in the MA group (83.3% *vs* 63.3% in YA and 57.1% in EL, p=0.001). The percentages of patients who switched to second-generation TKIs were similar in all three groups (36.7% in YA *vs* 30% in MA *vs* 32.1% in EP, p=0.559). There were the most of non-hematological AEs all grades in EP group (25% *vs* 13.3% in YA and 13.8% in MA, p=0.005). Hematological AEs also were common in EP group but not statistically significant (17.8% *vs* 10% in YA and in 12.1% in MA, p=0.156). The 5-years EFS in the MA group (88% (95%CI 82.1-96.9)) was significantly higher than in YA group (65.3% (95%CI 59.1-78.1)) and in EP group (60.2% (95%CI 49.5-73.7)). The 5-years OS in the EP group (74.7% (95%CI 65.9-89.0)) was significantly lower than in YA group (93.1% (95%CI 87.2-99.5)) and in MA group (90.8% (95%CI 85.8-97.8)). The number of deaths, both CML related or not related, was the largest in the EP group (25% *vs* 13.3% in YA and 13.8% in MA, p<0.001).

Table 1. Clinical features of the patients in different age groups.

	Whole cohort n=94	YA n=30	MA n=36	EP n=28	p
Gender (M/F), n	44/50	14/16	17/19	13/15	0.655
Median age, years (range)	53.4(18-78)	36.2(18-45)	55.9(46-64)	68.2(65-78)	<0.001
Sokal score Low/intermediate/high, %	41/42/17	67/23/10	44/42/14	11/64/28	<0.001
Euro score Low/intermediate/high, %	55/35/7	77/17/7	42/44/11	50/43/7	0.249
EUTOS score Low/high, %	81/19	76/27	83/17	85/14	<0.001
Any comorbidity: Yes/No, n (%)	33(35)/61(65)	3(10)/27(90)	12(33)/24(67)	18(64)/10(36)	<0.001
Median duration of therapy, months (range)	46.7(3-120)	40.6(3-114)	61.4(4-120)	38.2(6-90)	<0.001
Median follow-up, months (range)	52.5(6-120)	48.5(6-116)	64.3(7-120)	44.7(9-93)	<0.001

Summary/Conclusions: Results of this study indicate that age at diagnosis impacts the course of chronic myeloid leukemia treated with imatinib. The best clinical outcomes have middle age patients in terms of the highest rates achieved optimal therapeutic response and longer survival without events and overall survival. The degree of therapeutic responds in the elderly is comparable with that observed in younger patients, but the presence of comorbidity and more frequent occurrence of adverse events were affecting relatively lower overall survival. Although it might be expected that younger patient population has a better clinical outcome than patients middle age, a possible cause of poor outcomes is probably a late diagnosis at an advanced stage of the disease.

Enzymopathies, membranopathies and other anemias

CHARACTERIZATION OF HEMATOPOIETIC SAMPLES FROM PYRUVATE KINASE DEFICIENCY PATIENTS

R. Sanchez-Dominguez[1,*], O. Alberquilla[2], S. Lopez-Manzaneda[3], O. Quintana-Bustamante[3], P. Bianchi[4], M.D.M. Mañu-Pereira[5], J.-L. Vives-Corrons[5], I. Badell[6], J. Sevilla[7], J.A. Bueren[3], S. Navarro[3], J.C. Segovia[3]

[1]LACISEP (Advanced Therapies Unit), CIEMAT/CIBERER, [2]LACISEP (Advanced Therapies Unit), [3]Hematopoietic Innovative Therapies, CIEMAT, MADRID, Spain, [4,3]Fondazione IRCCS Ca' Granda, UO Oncoematologia, UOS Fisiopatologia delle Anemie, Ospedale Maggiore Policlinico, Milan, Italy, [5]Instituto de investigacion contra la leucemia Josep Carreras, [6]Hospital de Sant Pau, Barcelona, [7]Hematología y Hemoterapia, Hospital Infantil Universitario Niño Jesús, Madrid, Spain

Background: Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disease caused by mutations in the PKLR gene. PKD produces chronic non-spherocytic hemolytic anemia, which can be fatal during early childhood and may result in lifelong transfusion dependence that in some instances persists despite therapeutic splenectomy. Although not considered a standard-of-care, allogeneic bone marrow transplantation has been curative in a limited number of cases. These findings, and the evidence that PKLR gene mutations are likely the sole etiology of the disorder, make PKD a candidate for gene therapy. Our lab has developed a therapeutic Orphan Drug lentiviral product (EMA: EU/3/14/1330; FDA: DRU-2016-5168) for the treatment of PKD and is working to develop an efficient and safe gene therapy clinical trial for the treatment of PKD.

Aims: In order to improve this new treatment, a more deep knowledge of the disease and its associated pathophysiology is necessary.

Methods: To characterize the hematopoietic profile of this disease, we have standardized flow cytometry protocols to perform both a qualitative and quantitative study of different population subsets. These included subsets of the hematopoietic stem cell compartment, erythroid progenitors, reticulocytes, mature erythrocytes and other mature lineages. Human routine samples consisted of peripheral blood, bone marrow and cord blood from PKD patients. In addition, xenogenic engraftment studies in immnunodeficient (NSG) mice were also performed.

Results: Flow cytometry studies showed a clear imbalance in the erythroid populations. On the other hand, human PKD progenitors were able to engraft into NSG mice demonstrating that the disease does not likely impair hematopoietic stem cell capabilities.

Summary/Conclusions: Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disease caused by mutations in the PKLR gene. Our lab has recently developed a therapeutic Orphan Drug lentiviral product for the treatment of PKD. In order to improve this new treatment, we are also working to deep into the knowledge of the disease and its associated pathophysiology. Flow cytometry studies have shown a clear imbalance in the erythroid populations. Functionally, results in NSG mice we have demonstrated that the disease does not likely impair hematopoietic stem cell capabilities.

OSMOTIC GRADIENT EKTACYTOMETRY: A VALUABLE SCREENING TEST FOR HEREDITARY SPHEROCYTOSIS AND OTHER RED BLOOD CELL MEMBRANE DISORDERS

M.D.M. Mañu Pereira[1,*], E. Llaudet Planas[1], V. Rizzuto[1], J.L. Vives Corrons[1]

[1]Red Blood Cell Pathology and Hematopoietic Defects, Josep Carreras Leukaemia Research Institute, Barcelona, Spain

Background: Red blood cell (RBC) membrane disorders constitute one of the major causes of chronic hereditary hemolytic anemia. Main RBC membrane disorders, namely hereditary spherocytosis (HS), hereditary elliptocytosis (HE) and hereditary stomatocytosis (HSt), alter membrane cohesion, membrane mechanical stability, and RBC volume, respectively. As a consequence, RBC deformability is compromised leading to their premature removal from circulation, manifested as hemolytic anemia. New generation osmotic gradient ektacytometry has become a powerful procedure for measuring red blood cell deformability and therefore for the diagnosis of red blood cell membrane disorders.

Aims: The aim of this study is to evaluate osmotic gradient ektacytometry as an adequate assay to perform screening of membranopathies, focusing on the differential diagnosis between HS and non-spherocytic membrane defects such as HE and dHSt.

Methods: A total of 75 patients with chronic hemolytic anemia oriented as hereditary RBC membrane disorders (hemoglobin disorders discarded and negative Coombs test) were included during a period comprised between January 2015 and August 2016. Normal controls were obtained from blood donors. Osmotic gradient ektacytometry was performed using the osmoscan module of the Laser-assisted Optical Rotational Deformability Cell Analyzer: LoRRca MaxSis (RR Mechatronics). Evaluation of osmoscan parameters

robustness for HS diagnosis was performed using the receiver operating characteristic (ROC) curve analysis. The optimal cut-off was determined as the one with the highest likelihood ratio. Statistical analysis was operated with GraphPad Prism.
Results: Specific patterns of osmoscan LoRRca MaxSis were observed for each individual membranopathy. All HS curves were bell shaped but two different profiles were identified both presenting increased Omin, and decreased EImax and AUC. HE curves showed a characteristic trapezoidal shape with a decreased EImax, Omax and AUC. dHSt curve was bell shaped with a specific decrease in Ohyper and a slight increase in EImin. Reference ranges for each osmoscan parameter were established with 171 healthy subjects and compared with the values of the parameters obtained from the different RBC membrane disorders. ROC curve analysis was performed for HS and each one of the non-HS groups separately. The results determined that EImax was the parameter that better separated HS from normal controls and dHSt, while the Omin was the best to separate HS from HE. The optimal EImax cut-off to differentiate HS from normal controls was <0.5975 (sensitivity 98.46%, specificity 99.42%), while the optimal Omin cut-off to differentiate HS from HE was >159.0 (sensitivity 95.38%, specificity 85.71%). Expressing the results as% of variation in relation to the mean of our normal controls, the best combination of parameters for HS diagnosis would be EImax <-3% and Omin >5.2%. This combination of parameters (EImax <-3% and Omin >5.2%) was used as criteria to classify all the 246 samples included in the present study, and the result showed 62 samples detected as HS and 184 as no-HS. Of the 62 patients identified as HS, 61 were real HS (specificity 98.38%) and 1 was an HE. On the other hand, 4 HS patients were identified as non-HS (sensibility 93.85%).
Summary/Conclusions: We can conclude that, the inclusion of LoRRca osmoscan as a screening test in RBC membrane diagnostic workflow will signify an important advance for the accurate diagnosis of HS patients, as well as for the identification of HE and specially dHSt patients.

PB1841

RARE RED BLOOD CELL ENZYMOPATHIES INDUCED CHRONIC NONSPHEROCYTIC HEMOLYTIC ANEMIA: NEXT GENERATION SEQUENCING BASED MOLECULAR DIAGNOSIS

M. Jamwal[1,*], A. Aggarwal[1], P. Sharma[1], D. Bansal[2], P. Malhotra[3], A. Maitra[4], R. Das[1]
[1]Hematology, [2]Pediatrics (Hemato-Oncology), [3]Internal Medicine, Postgraduate Institute of Medical Education and Research, Chandigarh, [4]National Institute of Biomedical Genomics, Kalyani, India

Background: Red blood cell enzymopathies are mostly inherited autosomal recessive monogenic disorders. Mutations in the genes encoding red blood cell enzymes could lead to chronic nonspherocytic hemolytic anemia (CNSHA). The clinical manifestations are jaundice, cholelithiasis, splenomegaly, with usually normocytic normochromic hemolytic anemia. Phenotypes vary from having fully compensated hemolysis (without anemia) to severe hemolytic anemia requiring regular transfusions. Definitive diagnosis is difficult when biochemical test results are not consistent/fail to identify defects. Molecular diagnosis by gene-by-gene approach is expensive, time consuming and cumbersome as testing for multiple genes is required.
Aims: Use of targeted resequencing can expedite the molecular diagnosis where the cause for hemolysis remains unexplained after routine laboratory tests.
Methods: Ten patients with clinical and laboratory evidence suggestive of hemolytic anemia were enrolled. Various biochemical and molecular tests were used to exclude Glucose-6-phosphate dehydrogenase (G6PD) deficiency, thalassemias, hemoglobinopathies, autoimmune hemolytic anemia, hereditary spherocytosis and pyruvate kinase deficiency. Common G6PD and PKLR variants were excluded by molecular tests. Family history was negative in all the cases. Libraries were prepared using TruSight One sequencing panel and sequenced on MiSeq™ Sequencing System. MiSeq Reporter™ and VariantStudio™ v2.1 were used for analysis, classification, and reporting of genomic variants.
Results: Two patients with G6PD deficiency, six patients with pyruvate kinase (*PKLR*) deficiency and two patients with Glucose-6-phosphate isomerase (*GPI*) deficiency were found. Unexpected pyruvate kinase defects were found on targeted re-sequencing for six patients. Pyruvate kinase (PK) enzyme activity assay were within normal limits in all these cases. All the mutations were predicted deleterious by PolyPhen/ SIFT/ Provean/ mutpred and Mutationtaster. Mutations were validated in the parents/siblings (where available) to prove the mode of inheritance.
Summary/Conclusions: Unexpected PK deficiency were found after next generation sequencing analysis in the patients where PK enzyme levels were within normal limits. PK deficiency may be missed by conventional testing approaches. Our data demonstrates the clinical utility of next generation sequencing for molecular diagnosis. Timely detection of the cause in our patient is likely to be helpful not just in genetic counselling and future antenatal diagnosis, if required, but therapeutically as well. A splenectomy (performed at appropriate age) can ameliorate the anemia in such patients and can eliminate need for transfusions in those that need them.

COMPARISON STUDY OF THE EOSIN-5'-MALEIMIDE BINDING TEST, OSMOTIC FRAGILITY TEST AND CRYOHEMOLYSIS TEST IN THE DIAGNOSIS OF HEREDITARY SPHEROCYTOSIS

E. Özcan[1,*], Y. Oymak[1], T.H. Karapınar[1], S. Gözmen[1], S. Aydın Köker[1], N. Muminoğlu[2], S. Okur[3], R.C. Vergin[1]
[1]Pediatric Hematology, [2]Pediatric Hematolgy, [3]Pediatric Hematogy, Dr. Behcet Uz Children's Hospital, Izmir, Turkey

Background: The primary lesion in HS is loss of membran surface area due to defects of the membran protein. Cryohemolysis test and osmotic fragility (OF) test are used for screening. However no test for HS is 100% reliable. The eosin-5'-maleimide (EMA) binding test based on flow cytometry. Eighty percent of the fluorescent-labelled EMA binds to band 3 protein which is lost in HS due to protein 4.1, spectrin and ankyrin deficiency. Thus measurement of the flourescent EMA test detects all the different forms of HS.
Aims: In this study we aimed to evaluate the concordence of EMA binding test with other diagnostic parameters for HS.
Methods: The patients with HS were diagnosed according to clinical findings for hemolytic anemia, splenomegaly and spherocytes in peripheral blood. Hemogram, reticulocyte count, total/direct bilirubin, spherocytes in blood smear (BS), EMA binding test, OF test, and cryohemolysis test were obtained from pateints and control groups. Correlation between EMA, OF and cryohemolysis tests were evaluted.
Results: Twenty-five male, 17 female HS patients aged between 1.0-19.0 years and 38 male, 47 female healthy controls were evaluated. There were no differences between both groups in terms of age and sex (Table 1). The median (range) values of hemoglobin (%), reticulocyte count (%), mean corpuscular volume (fl), MCHC (%) and total bilirubin level were seen in Table 1. Besides MCV values there were differences between groups in terms of these parameters (Table 1). The median MCF of HS patients was significantly lower than that of healthy controls while cryohemolysis and osmotic fragility were higher in HS patients than healthy controls (Table1). There were moderate concordence between cryohemolysis and EMA test (r=-0.355, p<0.001). The sensitivity of EMA was 92.86%, specifity was 82.35%, PPV was%72.22, NPV was%95.89. EMA was superior diagnostic test to osmotic fragility. (sensitivity;%83.33, specifity;%76.47, PPV;%63.64 and NPV;%90.28). The sensitivity of cryohemolysis test was 90.48%, specificity was 94.12%, PPV was%88.37, NPV was%95.24.

Table 1. Comparison of Clinicaland Laboratory Findings in Hereditary Spherocytosis groups and Healthy Controls

	Hereditary Spherocytosis (n =42)	Healthy Controls (n = 85)	*P* Value
Sex, M/F	25/17	38/47	>0.05
Age, median (range), year	8.5 (1.0-19.0)	12.0 (1.0-20.0)	0.416
Hemoglobin, median (range), g/dL	10.8 (5.8-14.7)	14.2 (11-17.2)	<0.001
Reticulocyte, median (%)	6.1 (1.6-38.0)	1.1 (0.1-4.1)	<0.001
MCV, median (range), fL	77.5(73-90)	82(77-94)	0.994
MCHC, median (range), g/dL	33.0(27.0-37.0)	32.0 (27.0-35.0)	<0.001
Total bilirubin, median (range), mg/dL	3.3 (1.0-16.0)	0.9 (0.2-2.9)	<0.001
EMA (%), median (range)	18.38 (8-48)	26.43 (12-45)	<0.001
Cryohemolysis (%), median (range)	37.0 (2.0-83.0)	3.8 (2.0-14.0)	<0.001
OF (%)	62.2	37.8	<0.001

M/F; Male/Female, FC EMA;flowcytometric eosin-5'-maleimide, OF;osmotic fragility, HS; hereditary spherocytosis, MCHC; mean corpuscular hemoglobin concentration, MCV; mean corpuscular volume, BS; bloodsmear

Summary/Conclusions: In this study EMA-FC was more sensivitive and specificity than osmotic fragility. However specificity and PPV of cryohemolysis was higher than other test. Also we showed moderate concordance cryohemoysis and EMA test.
Although high sensitivity and specifity of EMA test there were need to use other tests together with family history of patient , physical examination, evaluation of blood smear and several tests for HS diagnosis.

PB1843

ADVANCES IN DIAGNOSIS OF HEREDITARY HEMOLYTIC ANEMIAS: THERMOGRAVIMETRY COUPLED WITH CHEMOMETRICS

R. Risoluti[1], S. Materazzi[1], F. Sorrentino[2], L. Maffei[2], C. Bozzi[3], P. Caprari[3,*]
[1]Department of Chemistry, Sapienza University of Rome, [2]Thalassemia Unit, S. Eugenio Hospital, [3]Haematology, Oncology and Molecular Medicine, Istituto Superiore di Sanità, Rome, Italy

Background: The differential diagnosis of hereditary hemolytic anemia is generally carried out by applying different diagnostic protocols depending on the specific congenital erythrocyte defects. Thermogravimetric analysis (TGA) coupled with chemometrics has recently been proposed as a rapid and cost effective diagnostic tool for β-thalassemia screening. This model, consisting of Partial Least Square-Discriminant Analysis (PLS-DA), permitted the discrimination of thalassemic patients and healthy individuals, using thermogravimetric curves of blood samples [1].
Aims: In this study, the capability of thermogravimetry in conjuction with a mul-

tivariate statistical analysis was investigated for the screening of hereditary hemolytic anemias due to different erythrocyte defects.
Methods: Whole blood samples collected in K_2EDTA were obtained, after informed consent, from patients suffering from congenital hemolytic anemias and were analyzed using the thermobalance TG7 (Perkin Elmer) without any pretreatment and the resulting curves were compared with those of healthy individuals. Two groups of hereditary hemolytic anemias were considered: the hemoglobinopathies (sickle cells anemia and thalassemia) and the erythrocyte membrane defects (hereditary elliptocytosis and hereditary spherocytosis).
Results: The characteristic profile of the blood sample thermal decomposition and the first derivative (DTG) of the TG curve showed that blood samples from anemic patients were clearly distinguished from those of healthy individuals as a result of different amounts of water and corpuscular fraction. The chemometric approach based on Principal Components Analysis (PCA) allowed a quick identification of differences between healthy and anemic patients in order to point out a model of prediction in patients with heterogeneous congenital hematological disorders.
Summary/Conclusions: The achieved results allow to consider the coupling TGA/Chemometrics as a promising diagnostic approach to provide a high-throughput and sensitive tool to obtain an early detection of hereditary hemolytic anemias using only a few microliters of blood without any pretreatment and with an hour of analysis time.

PB1844

DEVELOPMENT OF A POINT-SCORING SYSTEM FOR EARLY DIAGNOSTIC TESTING IN GAUCHER DISEASE: APPLICATION OF FINDINGS FROM THE GAUCHER EARLIER DIAGNOSIS CONSENSUS DELPHI INITIATIVE

S. Salek[1,*], D. J. Kuter[2], A. Mehta[3]
[1]School of Life and Medical Sciences, University of Hertfordshire, Hatfield, United Kingdom, [2]Center for Hematology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, [3]Department of Haematology, Royal Free Hospital, UCL School of Medicine, London, United Kingdom

Background: In the Western hemisphere, Gaucher disease (GD) type 1 is the most common GD phenotype, but the prevalence of GD type 3 is increasing. The spectrum of signs and symptoms of the different GD phenotypes ranges from fatal perinatal to asymptomatic adult disease, and the heterogeneity of its presentation contributes to both misdiagnosis and delays in diagnosis by clinicians unfamiliar with the disease. The Gaucher Earlier Diagnosis Consensus (GED-C) Delphi initiative determined which signs and patient co-variables are regarded by experts in GD as most indicative of GD types 1 or 3 in the early stages.
Aims: From the findings of the GED-C expert consensus, to generate a simple web-based point-scoring system (PSS) suitable for use across clinical specialties, that provides guidance based on patients' presenting signs as to whether GD diagnostic testing is appropriate.
Methods: An anonymous three-round Delphi process, conducted among a global panel of 22 expert physicians, established consensus on which signs and co-variables may be important in early GD type 1 and, separately, in early GD type 3. In round 1, free-text responses provided by the panel were categorized by an independent administrator. This categorization was checked and consolidated into summary factors by the non-voting co-chairs. In round 2, the factors were rated for importance by the panel using a 5-point Likert scale (1 = not important, 3 = important, 5 = extremely important). Any factors assigned an importance score of ≥3 by >75% of respondents were then rated for agreement in round 3, using a 5-point pivoted Likert scale (1 = strongly disagree, 3 = neither agree nor disagree, 5 = strongly agree). Consensus was defined as a score of ≥4 by >67% of respondents. Factors meeting this threshold were classified as major; all other factors were classified as minor. The co-chairs defined value ranges corresponding to mild, moderate or severe forms of five of the major signs of GD (anaemia, hepatomegaly, hyperferritinaemia, splenomegaly and thrombocytopenia). Panel members indicated whether they regarded each range as consistent with a GD diagnosis. This information was used in combination with the classifications of signs and co-variables as major or minor to create a prototype PSS.
Results: There was a 100% response rate in each round. Factors identified as major or minor in GD types 1 or 3 are given in the Table 1. There was 100% agreement that splenomegaly (≥3-fold enlargement) and disturbed oculomotor function (slow horizontal saccades with unimpaired vision) are major signs in GD, and these were assigned a score of 3 in the prototype PSS; other major signs and co-variables were assigned a score of 2. The panel was divided about whether severe anaemia, hepatomegaly, hyperferritinaemia and severe thrombocytopenia were consistent with a GD diagnosis, so these were assigned a score of 1. All minor signs and co-variables were assigned a score of 0.5.
Summary/Conclusions: A prototype PSS to inform GD diagnostic testing has been developed from the GED-C Delphi initiative. The PSS will be validated with retrospective patient data. Total patient scores based on presenting signs and co-variables will be used to determine empirically a minimum threshold score that captures positive tests for GD. Abstract submitted on behalf of the GED-C panel and the EHA Scientific Working Group 'Quality of Life and Symptoms'. Administration of the GED-C initiative was funded by unrestricted educational grants from Shire International GmbH.

Table 1.

	Score	Sign or co-variable	
Major signs and co-variables	3 points	Splenomegaly (≥ 3-fold enlargement) Disturbed oculomotor function (slow horizontal saccades with unimpaired vision)	
	2 points	Thrombocytopenia, mild or moderate (platelet count 50–150 x 10⁹/L) Bone issues, including pain, crises, avascular necrosis and fractures Family history of Gaucher disease Anaemia, mild or moderate (haemoglobin 95–140 g/L) Hyperferritinaemia, mild or moderate (serum ferritin 300–1000 µg/L) Jewish ancestry Disturbed motor function (impairment of primary motor development) Hepatomegaly, mild or moderate (≥ 3-fold enlargement) Myoclonus epilepsy Kyphosis Adult gammopathy – monoclonal or polyclonal	
	1 point	Anaemia, severe (haemoglobin < 95 g/L) Hyperferritinaemia, severe (serum ferritin > 1000 µg/L) Hepatomegaly, severe (> 3-fold enlargement) Thrombocytopenia, severe (platelet count < 50 x 10⁹/L)	
Minor signs and co-variables	0.5 point	Gallstones Bleeding, bruising or coagulopathy Leukopenia Cognitive deficit Low bone mineral density Growth retardation including low body weight Asthenia Cardiovascular calcification Dyslipidaemia	Elevated angiotensin-converting enzyme levels Fatigue Pulmonary infiltrates Age ≤ 18 years Family history of Parkinson disease Blood relative who died of fetal hydrops and/or with diagnosis of neonatal sepsis of uncertain aetiology

REGIONAL DISTRIBUTION OF GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY IN TURKEY AND EVALUATION OF CLINICAL FINDINGS

S. Sayin[1,*], G. Ozgur[1], M. Yildirim[1], E. Sezer Elci[1], C. Beyan[2]
[1]Hematology, Gülhane Educational and Research Hospital, [2]Hematology, TOBB University of Economics and Technology Faculty of Medicine , Ankara, Turkey

Background: Glucose-6-phosphate dehydrogenase (G6PD) deficiency is the most common inherited enzyme deficiency, that affects more than 400 million people around the world with more than 300 variants. According to data by the World Health Organization which was published in 1989; 7.5% of people in the world have at least one gene G6PD deficiency and this ratio is the highest in sub-Saharan Africa and Southeast Asia (15-26%). This ratio is in the range of 0.5-2.9% in Turkey, as United States and the neighboring countries to Mediterranean Sea. The epidemiological studies about G6PD deficiency in Turkey were mostly regional or limited to a city.
Aims: We aimed to evaluate in terms of regional distribution and clinical features of G6PD deficiency by screening the patients who applied for soldier recruitment.
Methods: The patients who applied for soldier recruitment between January 2011-March 2016, were analyzed retrospectively. Patients, who were diagnosed G6PD deficiency were scanned by using hospital patient information system. The patients' ages, the cities they lived, complaints and the stories of them were questioned. Complete blood count, serum AST, LDH, total and direct bilirubin levels of all the cases in the study were recorded. G6PD levels were measured by quantitative spectrophotometric methods in biochemistry laboratory. The World Health Organization (WHO) is divided G6PD enzyme deficiency into five classes based on enzyme activity levels and clinical findings.
Results: The distribution of the cities where the cases were living, was given on the map in Figure 1. Patients' average age, hemoglobin, and G6PD levels were 26.42±4.62, 14.68±1.51, and 0.86±0.81 respectively. According to clinical history of patients prior to diagnosis, 29 patients (20.7%) were diagnosed after acute hemolytic episodes. Of these patients 23, 4, 2, had hemolytic episodes due to drug, infection, chemical respectively. Subsequently, 78 (54.5%) and 27 (18.9%) of the remaining patients were diagnosed G6PD deficiency after the examinations due to hemolysis after favism and prolonged neonatal jaundice respectively. 6 patients (4.3%) were diagnosed of G6PD deficiency by screening because of family history, but they didn't have any hemolytic episodes before. After the patients evaluated with their clinical history and hemolysis findings; 6 patients (4.3%), who had chronic hemolysis, was considered compatible with Class I variant. 128 cases were considered as Class II variants.
Summary/Conclusions: G6PD enzyme deficiency in Turkey is seen most frequently in the Mediterranean region and the prevalence of G6PD deficiency in Central Anatolia and Aegean regions was seem to be over the Turkey average (2.9%). Nearly half of the patients had hemolytic anemia due to favism. It is followed by hemolysis due to neonatal hyperbilirubinemia and drugs. 128 (91.4%) patients who had severe G6PD deficiency with intermittent hemolysis, were considered as Class II variants.

CHARACTHERISTICS AND MANAGEMENT OF AUTOIMMUNE HEMOLYTIC ANEMIA : A SINGLE CENTER STUDY WITH 32 CASES

A.F. Yılmaz[1], H.D. Kiper Unal[1,*], T. Yuksel Karslı[2], M. Kilinc[2], F. Gediz[1], K.B. Bayman Payzin[1]
[1]Hematology, [2]Internal Medicine, Izmir Katip Celebi University Ataturk Research and Training Hospital, Izmir, Turkey

Background: Autoimmune hemolytic anemia (AIHA) is characterized by red blood cell destruction mediated with autoantibodies against to RBC antigens. Most common type is warm AIHA which can be either idiopathic or secondary to underlying disorders with immun disturbance. Determining the optimal therapy is a challenge because of insufficient data from prospective controlled trials.
Aims: To evaluate the clinical charactheristics, treatment responses and outcomes of our AIHA patients.
Methods: The clinical data of 32 patients with AIHA diagnosed and treated in our center between 2008 and 2016 were retrospectively analyzed.
Results: Median age at diagnosis of AIHA was 45 years (range:20-74). Male/female ratio was 1/1.3. 24 of 32 patients (75%) had primary AİHA and 8 (25%) had secondary AIHA with underlying disorders as SLE in 2 patients, , mixed connection tissue disease (MCTD) in 2, psoriatic arthritis in 1, chronic lymphocytic leukemia (CLL) in 1, marginal zone lymphoma in 1 and, chronic HCV infection in 1. Median Hemoglobin (Hb) level was 7.4 gr/dl and 5 patients also had thrombocytopenia (<150000) beside hemolytic anemia. Mean LDH level was 544, indirect bilirubin was 2.7, reticulocyte was 11.3%. 18/32 patients (56%) required transfusion. In all patients who required treatment (94%) corticosteroids were the first-line therapy with an initial response rate of 93%. Median steroid duration was 3 months range between 1.5 to 96 months. Relapse was occured in 15 of 30 patients who recieved steroid (50%) with the median time to relapse (TTR) of 12 months (range:5-72 months). 11/30 patients (37%) required second-line therapy; seven had undergone splenectomy, three recieved rituximab, and one recieved danasin. All of the patients who undergone splenectomy had CR in first month and relapse after splenectomy was seen in 5/7 patients (71%) with a median duration of 60 months. Of three patients who were treated with standard dose of Rituximab; two achieved CR and one did not achieve any response. One of two rituximab-responded patients relapsed at 26. and 60. months and re-treated by rituximab; still following with CR for 16 months.
Summary/Conclusions: Although corticosteroids are the first choice of initial treatment of AİHA, most of the patients relapse at follow up. Steroid dependency and intolerance are also challenging. Splenectomy is still a considerable option for second-line therapy because of its high response rates and long remission durations. Rituximab is the other effective second-line therapy option with similar response rates to splenectomy. Until prospective studies will be performed, retrospective data would help the clinicians to choose best treatment algorithm for AIHA.

Background: Gaucher disease (GD) is a multisystemic disease of lysosomal storage that is caused by deficient activity of the glucocerebrosidase enzyme resulting from a recessive autosomal hereditary mutation in the β-glucocerebrosidase gene. The accumulation of glucocerebrosidase in the lysomes damages the hematological, skeletal, and nervous systems and leads to three varieties of the disease: type 1, which is non-neuropathic, and types 2 and 3, which are neuropathic. In Mexico, the process by which patients with lysosomal disease are cared for was reorganized by the *Clínicas de Referencia Nacional y Grupos de Expertos en Enfermedades Lisosomales* (National Reference Clinics and Expert Groups on Lysosomal Diseases [EGLDs]), who created the *Guías de Práctica Clínica* (Clinical Practice Guidelines) for GD
Aims: This study aimed to evaluate the results obtained for 39 patients diagnosed with type 1GD (25 women and 14 men) through the National Reference Clinics and EGLDs
Methods: The clinical case of 39 patients was analyzed and punctual mutation of the β-glucocerebrosidase gene was determined. The patients were treated with imiglucerase enzyme at 60 UI/Kg every 14 days. The enzymatic activity of the β-glucocerebrosidase and the chitotriosidase was determined. We determinate concentration of hemoglobin and platelets. The degree of hepato-, splenomegaly, bone density and skeletal pain was evaluated.
Results: Four of the 39 patients were found to have been incorrectly diagnosed with GD, the remaining 35 patients completed the treatment goals, which included remission from hepatomegaly, splenomegaly, and skeletal pain. Additionally, increases in the hemoglobin and platelet concentration and bone mineralization were achieved, thereby attaining the patients' therapeutic goals, reducing the therapeutic dose required, and achieving the expected impacts on their health.
Summary/Conclusions: this reorganization of patient care successfully reduced complications, improved care, and optimized the use of resources and costs of GD treatment.

PB1848

NORMOCYTIC ANEMIA IS MORE COMMON THAN MICROCYTIC ANEMIA IN GASTRO-INTESTINAL CANCERS: A LARGE SINGLE CENTRE STUDY

F. Lourenco[1,*], F. Alibeygi[2], L. Barton[2], J.M. Yeung[3], S. Kadri[1], R. Krishna[2]
[1]Gastroenterology, [2]Haematology, [3]Colorectal Surgery, University Hospitals Leicester, Leicester, United Kingdom

Background: Microcytic anemia is traditionally associated with GI cancers and led to endoscopic investigations to evaluate for GI cancers.
Aims: We evaluated the haematological profile of a large series (855) of consecutive GI cancer patients at diagnosis in a university hospital.
Methods: This retrospective study analysed the full blood count of 265 colorectal cancer (CRC) patients over one calendar year and 590 patients with esophago-gastric cancers (OGC) over 3 calendar years. WHO guidelines were used to define anemia (Hb <130 g/L in males and <120 g/L in females). Further analysis was done based n severity of anemia (mild>110 g/L, moderate 80-110 g/L and severe<80 g/L), sex, age and tumour location.
Results: Among the 265 CRC patients, 116 (44%) were anemic, of which 72 (27%) were normocytic, 43(16%) were microcytic and 1 was macrocytic. 67/152 (44%)male patients were anemic, of which 42 were normocytic and 24 microcytic. 49/113 (43%) female patients were anemic, of which 30 normocytic and 17 microcytic. Patients above age of 60 had more normocytic anemia (31%) than microcytic anemia(12%), while among those below 60 had more microcytic anemia (30%) than normocytic anemia. Leucocytosis and thrombocytosis were seen only in 14% and 12% of CRC patients.
Among 590 OGC patients, 285 (48%) were anaemic, of which 221(37%) were normocytic, 51(9%) microcytic and 13(2%) macrocytic. 194/390 (50%) male patients were anaemic, of which 148 (38%) were normocytic and 38(10%) microcytic. 91/200 (46%) were anaemic, of which 73(37%) were normocytic and 13 (7%) microcytic. Among 392/590 esophagial cancers, 123 (31%) were normocytic and 25 (6%) were microcytic. Of 198/590 gastric cancers, 98 (49%) were normocytic while 26(13%) were microcytic. Leucocytosis and thrombocytosis was seen only in 16% and 13% of OGC patients.
Summary/Conclusions: There is a higher prevalence of normocytic anemia than microcytic anemia in Gastro-intestinal cancers almost at a ratio of 2:1. Normocytic anemia is more common in elderly patients and those with mild to moderate anemia. The causes may be multifactorial including anemia of chronic disease secondary to malignancy. This highlights the fact that GI cancers must be considered as a cause in normocytic anemia irrespective of iron deficiency and symptoms of GI cancer should be carefully explored and investigations triggered.

Gene therapy, cellular immunotherapy and vaccination

DEMONSTRATION OF FUNCTIONAL SIMILARITY OF PROPOSED BIOSIMILAR ABP 798 TO RITUXIMAB

H. McBride[1,*], G. Maher[1], H. Sweet[2], I. Foltz[2], J. Canon[1], S. Kuhns[1]
[1]Biosimilars Development, Amgen Inc., Thousand Oaks, United States, [2]Biosimilars Development, Amgen British Columbia, Burnaby, Canada

Background: Proposed biosimilars undergo comprehensive structural and functional characterization before they can be studied in confirmatory clinical trials. ABP 798 is being developed as a biosimilar to rituximab. The originator is approved for treatment of non-Hodgkin's lymphoma, chronic lymphocytic leukemia, severe rheumatoid arthritis, granulomatosis with polyangiitis, and microscopic polyangiitis.
Aims: ABP 798 was compared with rituximab sourced from the European Union (EU). Quality attributes assessed included binding properties (CD20, C1q, FcRn, and Fcγ receptors), antibody-dependent cell-mediated cytotoxicity (ADCC), complement-dependent cytotoxicity (CDC), and induction of apoptosis.
Methods: Binding of ABP 798 and rituximab to the CD20 antigen was characterized using a cell-based CD20 binding assay utilizing the human B-lymphoblastoid, WIL2-S, cell line. A direct binding ELISA was used to assess the binding of the Fc domain of ABP 798 to C1q. Binding of the Fc moiety of ABP 798 and rituximab to FcγRIa, FcγRIIa, FcγRIIb, and FcγRIIIa (158V) were evaluated in AlphaLISA® competitive binding assays. Binding to FcRn was evaluated by an AlphaScreen® competitive binding assay. ADCC activity was evaluated in a functional cell-based assay, with CD20-expressing WIL2-S cells used as target cells and NK92-M1 cells, stably transfected with human CD16 (FcγRIIIa [158V]), used as effector cells. CDC activity was evaluated in a functional cell-based assay using a CD20 expressing human B-lymphoblastoid WIL2-S cell line and baby rabbit complement. Induction of apoptosis was assessed by measuring activation of caspase 3/7 in SU-DHL-4 cells, a CD20-expressing human B cell lymphoma cell line.
Results: Relative binding (%) was comparable between ABP 798 and rituximab (Table 1).

Table 1.

Assay	ABP 798	Rituximab
CD20	91 – 105	82 – 105
C1q	85 – 100	85 – 89
FcRn	89 – 104	92 – 115
FcγRIa	94 – 98	87 – 95
FcγRIIa	96 – 102	96 – 106
FcγRIIb	96 – 108	93 – 109
FcγRIIIa (158V)	88 – 100	67 – 97

The dose response profiles and relative activity for ADCC and CDC were similar (mean ADCC relative activity: ABP 798, 88%; rituximab, 86%; mean CDC relative potency: ABP 798, 103%; rituximab, 104%). The dose response profile for induction of caspase 3/7 was comparable between ABP 798 and rituximab.
Summary/Conclusions: The results presented here suggest that ABP 798 is similar to rituximab sourced in the EU in terms of biological activity across the range of tested functions. These results provide a firm foundation for further clinical development of ABP 798.

PB1850

DELAYED EFFECT OF G-CSF ON THE CYTOKINE SECRETION THROUGH G-CSF MOBILIZATION OF PERIPHERAL BLOOD STEM CELLS IN CHILDREN WITH CEREBRAL PALSY

Y.-H. Lee[1,2,*], W.-J. Rah[2], H. Koh[1,2], H.-J. Jun[2], J.Y. Suh[1], H.J. Eom[1], M.J. Kim[3]
[1]Blood & Marrow Transplantation Center, [2]Department of Pediatrics, [3]Department of Rehabilitation Medicine, HANYANG UNIVERSITY MEDICAL CENTER, Seoul, Korea, Republic Of

Background: Granulocyte colony-stimulating factor (G-CSF) has been widely used to mobilize peripheral blood stem cells. In addition, it also has been tried to reveal the regenerative potential in various neurodegenerative diseases.
Aims: We investigated the short-term and delayed effects of infused G-CSF for peripheral blood stem cell (PBSC) mobilization on the various cytokine secretions in children with cerebral palsy (CP).
Methods: G-CSF (10μg/kg/dose) was administered subcutaneously for 4 days to the children with CP. In first group, blood levels of G-CSF, interleukin (IL)-6, IL-10, insulin-like growth factor (IGF-1), vascular endothelial growth factor (VEGF), and brain derived neurotrophic factor (BDNF) as well as mobilized total nucleated cell (TNC)/CD34+ cell counts in peripheral blood were compared between just before G-CSF injection (D+0) and 1 day after 4 days of G-CSF injections (D+5). In second group, cytokine levels were compared between D+0 and 1 month after 4 days of G-CSF injection (D+30). Cytokine levels were measured by enzyme-linked immunosorbent assay.
Results: Baseline levels of G-CSF were significantly increased (p=0.000) and IGF-1 decreased (p=0.011) at D+5 after 4 days of G-CSF administration compared to control group. In contrast, other cytokine levels including IL-6, IL-10, VEGF, and BDNF did not show any significant changes between before and after G-CSF administration. CD34+ cell counts (p=0.000) as well as TNC counts (p=0.000) were significantly increased from D+0 to D+5 in children who received G-CSF compared to children received placebo. Regarding delayed effect of G-CSF administration, G-CSF levels were significantly increased from baseline to D+30 (p=0.000), along with the increase IL-10 (p=0.035) and VEGF levels (p=0.011) and the decrease of IGF-1levels (p=0.014).
Summary/Conclusions: G-CSF which administered to mobilize PBSCs could induce the delayed effects on the levels of G-CSF itself as well as of other cytokines which could affect on the neuroregenerative potential. Further studies would be warranted to reveal the mechanism and clinical significances of these delayed effect of G-CSF or mobilized PBSCs.

PB1851

MYD88 IN PRAME GENE ACTIVATION

V. Misyurin[1,*], N. Lyzhko[1], A. Misyurina[2], J. Finashutina[1], V. Tikhonova[1], L. Kesaeva[1], O. Solopova[1], N. Kasatkina[1], M. Baryshnikova[1], E. Misyurina[3], A. Prokophiev[4], A. Misyurin[1]
[1]"N.N.Blokhin Russian Cancer Research Center" Ministry of Health, [2]National Research Center for Hematology, [3]City Clinical Hospital No52 Moscow Health Department, [4]Moscow state Academy of Veterinary Medicine and Biotechnology - MVA by K. I. Skryabin, Moscow, Russian Federation

Background: PRAME is the most frequently expressed non-X-chromosomal cancer-testis gene in solid and hematological cancer. It is important, because PRAME often has a bad prognostic significance. In early studies was found that PRAME frequently coexpressed in translocation-harboring (like t(8;21), t(15;17) and t(9;22)) haematological diseases. Authors supposed that chimeric genes are activators of PRAME expression. But in large cases with normal karyotype PRAME is also expressed. Another reason for PRAME expression is promoter demethylation. But demethylating agents cannot activate PRAME expression in hematological cells taken from healthy donor. So presence of chimeric genes and methylation status only are not enough to explain why PRAME can be expressed in high level. Wadelin *et al.* found that PRAME expression level was increased in cell during lipopolysaccharide-treatment conditions. Role of MYD88 in this process still be unknown.
Aims: To check if MYD88 participates in activating PRAME expression in leukemia cell lines.
Methods: Three cell lines were used for incubation with anti-PRAME antibody: chronic myeloid leukemia cell line K562 with high PRAME expression level (645%), acute monocytic leukemia cell line THP-1 with intermediate PRAME expression level (2,92% relative to ABL) and acute myeloid leukemia cell line NOMO-1 with low PRAME expression level (0,46%). All cell lines were incubated in RPMI 1640 with addition of LPS in final concentration 10 ng/ml. After 1 and 4 hour of incubation total RNA was extracted and PRAME and MYD88 expression levels were measured.
Results: After 1 and 4 hours of experiment in K562 cell line PRAME expression level was increased in 2,7 and 7 fold under control, respectively, and MYD88 expression level increased in 1,1 and 2,5 fold under control. In THP-1 line PRAME expression level was increased in 20 and 25 fold, respectively, and MYD88 expression level was increased in 5,5 and 6,5 fold. In cell line NOMO-1 PRAME expression level was increased in 10 fold after 1 hour and in 14 fold after 4 hours, and MYD88 expression level was increased in 2,4 and 3,2 fold after 1 and 4 hours of experiment, respectively. Strong correlation between MYD88 and PRAME expression levels was observed (Pearson correlation coefficient 0,98).
Summary/Conclusions: We conclude that LPS after binding with TLRs initiates activating signal to PRAME gene via MYD88.

Hematopoiesis, stem cells and microenvironment

PB1852

PD-1 IS HIGHLY EXPRESSED ON MEMORY T-CELL SUBSETS RESIDING IN BONE MARROW BUT NOT IN PE-RIPHERAL BLOOD IN HEALTHY INDIVIDUALS

N. Popova[1,*], M. Drokov[1], A. Kuchmiy[2], A. Vdovin[2], J. Davydova[3], L. Kuzmina[1], D. Dubnyak[1], E. Mikhalcova[1], V. Vasilyeva[1], O. Koroleva[1], Z. Konova[1], I. Galtseva[3], G. Efimov[2], E. Parovichnikova[1], V. Savchenko[1]
[1]Bone marrow transplant department, [2]Laboratory of post-transplant immunology, [3]Laboratory of immunophenotyping, National Research Center for Hematology, Moscow, Russian Federation

Background: Recently memory T lymphocytes were shown to be a highly heterogeneous cell compartment comprising different phenotypes, functional activities, gene expression profiles and survival capacities. Phenotypically due to the differentiation stage and functional activities memory CD8+ T cells can be divided into stem cell memory (Tscm), central memory (Tcm), terminal memory (Ttm), effector memory (Tem) and terminal effector (Tte) and reside in bone marrow (BM) as long-lived persistent T cells [Mahnke YD *et al.*, 2013]. Programmed cell death protein 1 (PD-1) is well known as a negative immune regulator of T cells that has detrimental effects on anti-viral, anti-tumor immunity, mediates tissue tolerance to protect against immune-mediated tissue damage. Currently anti-PD1 immunotherapies are among the most effective anti-cancer immunotherapies available. PD1 pathway blockade is a key pathogenetic mechanism [Boussiotis VA *et al.*, 2014]. Understanding the influence of PD-1 pathway on memory T cell homeostasis in BM might be critical for improving treatment of patients with cancers and hematological malignancies, but is still not well understood.
Aims: To evaluate PD-1 expression on distinct memory T cell subsets in BM and PB of healthy donors.
Methods: The first portion of BM and a sample of PB were obtained from healthy donors (n=10, m=6, f=4) with age 37.5 (22-53) years old.. Numbers of white blood cells (WBC) in BM and PB samples were evaluated by Sysmex XE-2100 hematology analyzer. 1*10^6 of WBC (excluded nucleated red blood cell) from BM and PB were stained using "lyse-wash-stain" standard protocol. The CD8-APC-Cy7, CCR7-PE-Cy7, CD28-PE, CD45R0-FITS, PD1-APC antibodies were used for cell staining and 7-AAD was used for to discriminate dead cells during flow cytometry.
Results: PD1 expression by T memory cell subsets is shown in the Table 1 (median with interquartile range). The percentage of PD1+ cells within Tcm CD8+ subset was 34,2%±8,033% in BM *versus* 10,4%±1,23% in PB. Similar trend was observed in other subsets: Tscm, Tem, Ttm, Tte. Median of PD1+ CD8+ cells were 3,8%±1,015%, 22,7%±6,39%, 42,7%±7,86%, 21,9%±4,047% and 2,6%±0,41%, 6,6%±2,59%, 12,7%±1,25%, 8,9%±0,825% in BM and in PB respectively.

Table 1.

PD1 expression (median with IQR)	Tnv+Tscm $CD45R0^{-}$ $CCR7^{+}CD28^{+}$	Tcm $CD45R0^{+}$ $CCR7^{+}CD28^{+}$	Ttm $CD45R0^{+}$ $CCR7^{-}CD28^{+}$	Tem $CD45R0^{+}$ $CCR7^{-}CD28^{-}$	Tte $CD45R0^{+}CCR7^{-}$ $CD28^{-}$
BM	3,8 %±1,015% ns	34,2%±8,033% p<0,01	42,7%±7,86% p<0,01	22,7%±6,39% p<0,01	21,9%±4,047% p<0,01
PB	2,6 %±0,41%	10,4%±1,23%	12,7%±1,25%	6,6%±2,59%	8,9%±0,825%

Summary/Conclusions: We found higher frequencies of PD-1 expressing memory BM T cells comparing to PB. This might point to the important roles of PD-1 in regulation of memory T cells homeostasis in BM. In physiological conditions PD-1 is thought to neutralize self-reactive naive T cells that in its turn leads to restraining T cells excessive activation and blockade the development of autoimmunity in BM. On the other hand low expression of PD1 on T cells in PB can be explained by needs the opportunity for prompt reactivity with pathogens that also provide normal «robust control» and prevent developing of a disease.

PB1853

BONE MARROW STROMAL CELLS MAY HAVE GENETIC ABERRATIONS AND ARE CAPABLE TO GAIN THEM IN A CULTURE

I. Barkhatov[1,*], N. Tsvetkov[1], D. Ershov[1], T. Gindina[1], A. Shakirova[1], M. Nikolaeva[1], A. Potter[1], L. Zubarovskaya[1], B. Afanasyev[1]
[1]R.M. Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, First Pavlov Saint Petersburg State Medical University, St.Petersburg, Russian Federation

Background: Stromal microenvironment posses a key role in the regulation of both normal hematopoiesis and its reconstitution after hematopoietic stem cell transplantation (HSCT). Recent data supports the idea that bone marrow stromal cells (BMSC) also have genetic aberrations and may tightly involved in the pathogenesis of HSCT complications. These findings justify the need for more detailed study of genetic aberrations in BMSC.
Aims: The **aim** of this study was to evaluate genetic aberrations in BMSC and check the ability to gain them in coculture system.
Methods: The interaction of BMSC with hematopoietic tumor cell lines bearing specific genetic aberrations (BCR-ABL fusion transcript for K-562 and JAK2 V617F mutation for Uke-1 cell line) was investigated in stromal cells harvested from 17 patients and 8 healthy donors. We performed cultivation of BMSC monolayer and tumor cells suspension using semipermeable membrane plates inserts with different pore size (0,4 μm and 3,0 μm) in order to exclude direct cell-to-cell contact. We looked also for existing specific genetic aberrations (point mutations and fusion transcripts) in BMSC of patients with the respective aberration in their leukemic clone. For this purpose we used both karyotyping (7 patients) and RQ-PCR method. BMSC were examined by flow cytometry to evaluate the possible contamination with cells of hematopoietic lineage.
Results: We investigated the BMSC karyotype in seven patients and only one case led us to a remarkable finding. The clonal chromosomal rearrangement t(1;7) was detected in 25% of BMSC metaphases. Interestingly, this aberration was never detected in patient's leukemic cells.
We also examined BMSC from leukemia patients bearing recurrent genetic abnormalities and in one case the leukemia-specific marker was detected by RQ-PCR - we observed expression of ETV6-RUNX1 gene (≈0,02%) in BMSC by patient with t(12;21) acute lymphoblastic leukemia. At the moment of BMSC culture initiation ETV6-RUNX1 expression in patient's bone marrow was detected at high level (ETV6-RUNX1/ABL*100=321%). Before carrying out RNA extraction BMSC were harvested after the second passage and no contamination with CD45+/CD34+ cells by flow cytometry was observed (50,000 events collected from the sample). When BMSCs and Uke-1 cell line were cocultured by using of 3,0 μm pore culture dishes inserts, the BMSC population gained the Jak2V617F mutation (allele burden ≈ 30,39%). We reproduced similar experiments with the K-562 cell line and got similar results - CD45+ cells were also detected in BMSC population (≈ 30%). Moreover we detected CD45+ non-cellular particles by flow cytometry analysis. Implying K-562 cells are not likely to cross the semipermeable membrane (3,0 μm pores *versus* 20,0 μm cells as measured during microscopy). Besides BCR-ABL gene expression in BMSC was detected by RQ-PCR (BCR-ABL/ABL*100=19%). We repeated same test with 0,4 μm pore inserts and without them in order to check implication of cell-to-cell interaction. We didn't obtain any similar results with smaller pores, but the fusion transcript was detected in CD45- BMSC population when these two cell populations weren't devided. Both findings point out at possible horizontal gene transfer mediated by membrane vesicles larger than 0,4 μm and direct whole cell fusion.
Summary/Conclusions: Our data stands for the existence of horizontal gene transfer between leukemic clone and BMSC. This process seems to be mediated by membrane vesicles larger than 0,4 μm in size, though cell fusion can also take place. We also confirmed the fact BMSCs can bear clonal genetic rearrangements which are not specific to tumor cell populations. These findings show tight interaction between tumor and microenvironment cells and can partly explain nature of PCR-based MRD persistence in complete remission.

PB1854

CIRCULATING ENDOTHELIAL PROGENITORS CELLS AND METABOLIC FACTORS IN CHILDHOOD CANCER SURVIVORS

E. Athanasopoulos[1], G. Martimianaki[1], H. Kampouraki[1], M. Stratigaki[1], E.A. Markaki[1], N. Katzilakis[1], E. Stiakaki[1,*]
[1]Pediatric Hematology - Oncology, University Hospital of Heraklion, University of Crete, Heraklion, Greece

Background: Circulating Endothelial Progenitor Cells (CEPCs) play a significant role in the maintenance of vascular integrity,balancing the anti-coagulation mechanisms and modulating the immune system by regulating the leukocyte trafficking, as well as controlling the vascular tone. Additionally, it is well-established, that patients who underwent chemotherapy have increased incidence of hypertension and obesity. Nevertheless, numerous studies have shown a negative correlation between CEPCs and obesity, underlining poor vascular repair.
Aims: The study of CEPCs in children who received chemotherapy for Acute Lymphoblastic Leukemia (ALL) and solid tumors (ST) and the investigation of their levels in correlation with patients Body Mass Index (BMI) and blood pressure (BP) regarding the time following treatment.
Methods: Peripheral blood from children with ALL (n=77), ST (n=81) and children without malignancies as control group (n=71) were studied. Four colour flow cytometry was performed to determine the subpopulations CD34+CD 45negdimCD133+, CD34+CD45negdimVEGFR2+ and CD34+CD45negdim-CD133+VEGFR2+ of CEPCs. The BMI of the patients was calculated and the BMI percentile was established specific by the age and gender. Normal weight defined with BMI percentile over 5th and bellow 85th percentile, and overweight/obesity over 85th percentile. The systolic blood pressure (BP) was measured and the percentile was calculated specified by the age, gender and height. Normal BP was defined BP over 5th and bellow 90th percentile and hypertension with a BP over 90th percentile. The post treatment period of time was divided in three groups under or equal of 1 year, 1 to 3 years, and equal and over 3 years. The statistical analysis was conducted using t-test (Holm-Sidak) and 2way ANOVA (Tukey's multiple comparisons test).

Results: The mean values of CEPCs subpopulation CD34+CD45negdimVEGFR2+ estimated in ALL, ST and Controls were 0.00360 (SE=0.00072),0.00613 (SE=0.00146) and 0.002953 (SE=0.0004) respectively. The mean percentage of CD34+CD45negdimCD133+VEGFR2+ in ALL, ST and Controls was 0.00331 (SE=0.00072), 0.00499 (SE=0.00113) and 0.002663 (SE=0.00037). The correlation of CEPCs showed statistical significant difference of CD34+CD45negdimVEGFR2+ between the ST and controls (Mean Diff 0.003174, 95CI of diff 7.716e-005 to 0.006272). In ALL the levels of CD34+CD45negdimVEGFR2+ the 1st year after treatment completion were 0.00458(SE=0.0026), during 1-3years 0.0031(SE=0.00066) and >3 years 0.003423(SE 0.00081). The levels of CD34+CD45negdimCD133+VEGFR2+ during the 1st year after chemotherapy have a mean value 0.0045(SE=0.0026), 1-3 years 0.0027(SE=0.00063) and >3years 0.0031(SE=0.00081). In the ST group the mean value of CD34+CD45negdimVEGFR2+ the 1st year after treatment was 0.0114 (SE=0.0048),1-3years 0.0047(SE=0.0013) and >3 years 0.0036(SE=0.0008). Whereas the percentage of CD34+CD45negdim CD133+VEGFR2+ the 1st year after chemotherapy was 0.0092 (SE=0.0037),1-3 years 0.0034(SE=0.00097)and>3 years 0.00336(SE=0.00085).Statistical significant results were calculated for the levels of CD34+CD45negdimVEGFR2+ in ST group between the groups <1 year and over years' post treatment(Mean Diff 0.007747, 95 CI of diff 0.0002441 to 0.01525). The study of body weight in ALL and ST groups in relation with CEPCs showed no statistical significant difference, although a negative trend between obesity and CEPCs was found in the ALL group and a positive one in the ST group. The same trend also appeared in BP between ALL and ST regarding the CEPCs, with hypertensive patients in ALL group having higher levels of CEPCs than the ST hypertensive individuals.

Summary/Conclusions: The higher levels of CEPCs were estimated in ALL and ST just after treatment completion with a gradual decrease as time passes. The highest percentages of CEPCs were evaluated in ALL patients with normal weight and blood pressure in contrast with the solid tumor group. Further invstigation is necessary to highlight the importance of these data.

PB1855

HEMATOLOGICAL PARAMETERS IN NATIVE HIGHLANDERS OF LADAKH AGED 4-19 YEARS

S.K. Das[1,*], Y. Uday[1], D. Katoch[1], V. Nair[1]
[1]Hematology, Army Hospital (Research & Referral), New Delhi, India

Background: High altitude (HA) has always intrigued physiologists because of the remarkable ability of man to adapt to the hostile environment. Hematological changes associated with HA exposure is believed to be driven by hypobaric hypoxia of HA. Majority of the studies on HA physiology and hematological adaptation have focused on the hematological adaptation in lowlanders visiting HA or have compared the hematological profile of native highlanders from Andes and Tibet with those of the neighboring lowlanders. These studies have mostly been directed towards adult population with no or little reference to children and adolescent age groups. Moreover these studies have been done mostly on the highlanders of Andes and Tibet with no data on Indian highlanders.

Aims: We aimed at assessing hematological parameters in native highlanders in the age group of 4- 19 yrs and compare the same with Indian lowland population as well as native highlanders around the globe.

Methods: A total of 390 native highlanders of Ladakh in the age group of 4-19 yrs with no history of travel to lowland were taken for the study. A written informed consent was taken from the parents of all the subjects before starting interviewing them for the laboratory investigations. After taking antiseptic precautions, blood samples were drawn from the ante-cubital vein and complete hemogram including red blood cell indices were measured. The study subjects were stratified into five age groups (less than 5y, 5-8y, 8-10y, 10-12y, 12-15y and children more than 15y). Appropriate statistical analysis was done to compare the hematological parameters between the stratified age groups as well as between boys and girls.

Results: A total of 197 girls and 193 boys were included in the study. The mean age of the subjects was 128±80 (mean±2SD) months. The mean hematocrit value increased with age (38.68±2.51% in <5 yrs age group to 43.84±2.04% in >15 yrs age group). Similarly the mean corpuscular volume (MCV) also showed a rising trend with age (79.07±3.36 fL in <5 yrs age to 85.66± 2.72 fL in >15 yrs age). In contrast to the rising values of hematocrit and MCV we found that the mean corpuscular haemoglobin concentration (MCHC) decreased with age from 36.91±2.85% at <5 yrs of age to 33.78±2.31% at >15 yrs of age. The variations among the age groups are significant for hematocrit, mean corpuscular volume (MCV) and MCHC ($p<0.01$). On comparison of hematological parameters between boys and girls we found that the mean hemoglobin concentration in girls (13.99±0.29 g/dL) was significantly lower than boys (15.43±0.28g/dL). The same findings were replicated in the mean RBC count (4.79±0.08 in girls v/s 5.07 ±0.08 in boys) and mean hematocrit (39.49±0.82% in girls v/ 41.57±0.82% in boys). The mean MCHC in boys (37.23±0.93%) was significantly higher than those in girls (35.69±0.94%). The mean platelet count in boys was significantly higher than in girls ($p=0.0003$) (Figure 1).

Figure 1.

Summary/Conclusions: The hematological adaptation of Ladakhi kids is different as compared to other native highlanders. There is also a significant difference in the hematological response to hypobaric hypoxia with growing age and between boys and girls.

PB1856

AGE VARIATION OF B-CELL PRECURSORS IN BONE MARROW: NORMAL VALUES AS A REFERENCE FOR MDS IN BRAZIL

I. Lorand-Metze[1,*], A.L. Longhini[1], G. Oliveira-Duarte[1], R.P. Correia[2], M.C. Santos-Silva[3], M.R. Ikoma[4], E. Xisto Souto[5], A. Sandes[6], A. Frisanco Oliveira[7], K. Metze[8]
[1]Hematology - Hemotherapy Center, University of Campinas, Campinas, [2]Laboratory of Hematology, Hospital Albert Einstein, São Paulo, [3]Laboratory of Experimental Oncology, Fedreal University Of Santa Catarina, Florianópolis, [4]Laboratory of Cytometry, Hospital Amaral Carvalho, Jaú, [5]Laboratory of Hematology, DASA, [6]Laboratory of Hematology, Laboratórios Fleury, São Paulo, [7]Laboratory of Hematology, Childrens' Cancer Hospital, Barretos Cancer Center, Barretos, [8]Pathology, University of Campinas, Campinas, Brazil

Background: Decrease of bone marrow (BM) B-cell precursors (BCP) is an important diagnostic feature in myelodysplastic syndromes (MDS). Moreover, their number is associated with patients' overall survival. However, BCPs vary with age in normal BM.

Aims: In a multicenter study from the Brazilian Group of Flow Cytometry we analyzed the variation of BCPs in normal BM according to age, antibody combinations used for quantification and reproducibility after a centralized reanalysis. We set up a reference pattern of normal values for evaluation of patients with a suspected MDS.

Methods: In a retrospective study including 10 centers we retrieved analyses of BM donors and cases examined for elucidation of transitory reactive cytopenias presenting a normal BM immunophenotyping. BCPs were enumerated as CD19/CD34/CD45/CD10 cells (panel 1) or CD19/CD34/CD45 cells (panel 2), among the total nucleated cells and as percentage among CD34+ cells. Statistics: multiple regression to analyse the dependence of BCS from the variables analysed.

Results: 134 cases were included. Panel 1 was applied in 106 cases (all centers) and panel 2 was used in 28 cases (3 centers). Age range: 10 months to 89 years. In the same age range, values for panel 2 were lower than those for panel 1. In a multiple regression,**%** BCP/total cells=-0.389 "log age" (years) – 0.313 (for panel 2)+correction factor for labs +1.873. The correction factor for labs was 0 to -0.40. Age explained alone 49.6% of the variance of% BCPs/total cells, while "laboratory" explained 5.2% and panel used explained only 0.8%. Age explained only 24.9% of the variance of BCPs/CD34+ cells.

Table 1.

	% total CD34+ cells	BCPs/total cells	BCPs/CD34+ cells
0-6 years (n=10)	3.05% (1.5 - 5.1)	2.8% (0.35-3.8)	62.1% (22.8-62.6)
7-18 years (n=19)	1.43% (0.25 – 3.2)	0.4% (0.02-1.8)	41.5% (3.1-64.5)
19-55 years (n=70)	0.84 (0.07-2.76)	0.13% (0.02-0.8)	20.8% (2.6-60.4)
>56 years (n=35)	0.71% (0.06-2.48)	0.08% (0.02-0.68)	12.9% (1.3-55.2)

Summary/Conclusions: in a normal population BM B-cell precursors varied mainly with age, but were also dependent on technical peculiarities of operators and equipments. Analysis by phenotype and as percentage of total cells was more accurate and less susceptible to variation.

PB1857

PERIOSTIN/BIGH3 RATIO AS A PROGNOSTIC MARKER OF IDIOPATHIC THROMBOCYTOPENIA AFTER ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION FOR THE PATIENTS WITH ACUTE MYELOGENOUS LEUKEMIA

Y.J. Lee[1,*], S.K. Sohn[1], H.-J. Kim[2], T.I. Park[3], J.Y. Ham[4]
[1]Department of Oncology/Hematology, [2]Biochemistry and Cell biology, [3]Pathology, [4]Laboratory, Kyungpook National University Hospital, Daegu, Korea, Republic Of

Background: Disrupted hematopoiesis is life-threatening complication of allogeneic hematopoetic cell transplantation (allo-HCT). The interactions of haematopoietic stem/ progenitor cells (HSPCs) and bone marrow (BM) microenvironment, niche(s), control the homeostasis of BM. TGF-b induced gene 3 (BIGH3), one of BM extracellular matrix (ECM) which is produced by niche cells maintain the homeostasis and regeneration of BM.
Aims: We analyzed the relationship between the idiopathic thrombocytopenia after allo-HCT and the BM expression of periostin as the only paralogue of BIGH3.
Methods: We reviewed twenty patients who transplanted with matched sibling donor for acute myelogenous leukemia at Kyungpook National University Hospital from January 2010 to August 2015. BM biopsy specimens at the time of day 28, day 90, day 180, day 365 since allo-HCT were decalcified and stained with primary antibody of BIGJ3 and periostin. Expression of periostin in BM slides were reviewed by pathologist as follows; normal (0), minimal staining around blood vessels; (+1), sparse staining and/or focally staining; (+3), diffuse and strong staining; (+2), between (0) and (+3).
Results: The median age at transplant was 38.5 years (range, 17-68 years) and male was 13 patients (65%). Twelve patients (60%) were in CR1 (complete remission), 8 (40%) in CR2. Thirteen patients (65%) received myeloablative conditioning regimen. The median dose of CD34+ cell was 3.87×10^6/kg (range, $1.6\sim7.67\times10^6$/kg). All patients achieved the neutrophil engraftment with a median time of 13 days (range 9-24days). The median time of platelet engraftment was 15.5 days (range, 13-77days). Idioathic thrombocytopenia developed as follows; 13 patients at day 28, 16 at day 90, 6 at day 180, and 3 at day 365. There was no significant difference between idiopathic thrombocytopenia and the expression of BIGH3 or Periostin (p=0.128) However, BM with thrombocytopenia manifested the low periostin/BIGH3 ratio (p=0.007). Acute GVHD was observed in 12 patients (60%) and chronic GVHD developed in 13 patients (65%). The developemnet of thrombocytopenia dose not differ according to acute and chronic GVHD (p=0.847) (Figure 1).

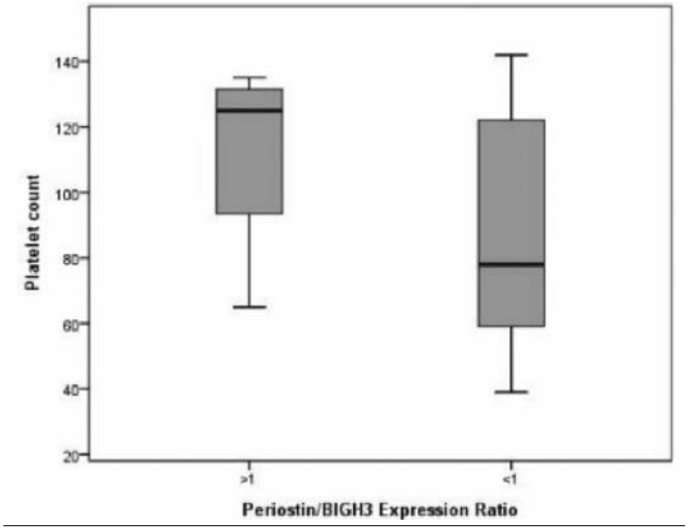

Figure 1.

Summary/Conclusions: The periostin/BIGH3 might represent the status of BM niche during the homeostasis and regeneration of hematopoiesis. High periostin/BIGH3 ratio could predict the recovery of the idiopathic thrombocytopenia.

PB1858

ASSOCIATION WITH OMENN SYNDROME AND CYSTINURIA: CASE REPORT

T. Patiroglu[1,*], M. Cansever[2], S. Coşkun[3], M. Karakukucu[1], N. Baydilli[4]
[1]Pediatric Hematology, [2]Pedıatrıc Immunology, [3]Pedıatrıc Nephrology, [4]Urology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Omenn syndrome is one type of combined immunodeficiency, characterized with hepatosplenomegaly, lymphadenopathy, recurrent infections and has an autosomal recessive pattern of inheritance. T lymphocyte count can be normal in peripheral blood but their functions are impaired. B lymphocyte count is very low to none. Cystinuria is renal reabsorption defect of dibasic amino acids, inherited autosomal recessive. Because cysteine solubility is lower than other amino acids cysteine stones are formed in kidneys. In the literature, no association was found between Omenn Syndrome and cysteine stones hence, our case is very interesting.
Methods: 5 months old girl applied to the Pediatric Immunology Department of Erciyes University Children Hospital with skin eruption. There was no family history for immune deficiency and no consanguineous marriage between mother and father. Patient had one sibling who is healthy. Patient was not performed with BCG or other live vaccines. In her physical examination, we observed exfoliative erythroderma and hepatomegaly. In laboratory examination, leukocyte count 6540/mm^3, absolute neutrophil count 2270/mm^3, absolute lymphocyte count 1560/mm^3, absolute eosinophil count 2220/mm^3, serum IgG level 171mg/dl, IgA level 5,81mg/dl, IgM level 24,5mg/dl, IgE level 1270 mg/dl were found. T lymphocyte count 1092/mm^3, B lymphocyte count 6/mm^3, NK count 332/mm^3 were found respectively. Blood sample of patient was sent to Erasmus for genetic analysis. The patient had no full-match family donor. Hence, haploidentical bone marrow transplantation from her father was planned. In preparation for bone marrow transplantation, bilateral kidney stones were showed in abdominal CT. Cystinuria was detected in urine and thought to be bilateral cysteine Stone. Percutaneous nephrolithotomy operation was performed, then the patient was given scholl solution. Stone analysis revealed to be cysteine stone.
Results: Association with two different diseases inherited autosomal recessive is very interesting. Challenging incident that can be caused by a reason or it can be only coincidence? In Omenn Syndrome is known to be sequencing alteration of cysteine and tyrosine amino acids. Perhaps, cysteine stones took form as a result of this alteration.

PB1859

LABEL-FREE IMAGING BY AUTO-FLUORESCENCE PERMITS IDENTIFICATION OF ERYTHROID PRECURSORS IN BONE MARROW AND DETECTS CHANGES OF SOLUBILITY OF HEMOGLOBIN IN ERYTHROCYTES

I. Lorand-Metze[1,*], F. Borges da Silva[2], M. Falconi[1], K. Metze[2,3]
[1]Hematology - Hemotherapy Center, [2]National Institute of Photonics applied to Cell Biology (INFABIC), [3]Pathology, University of campinas, Campinas, Brazil

Background: In the fluorescence lifetime imaging (FLIM) technique, the image contrast is created by determining the delay of the fluorescence photon emission at each pixel of the image and transforming it in pseudo-colors. This delay, also called lifetime depends on the type of molecules and their physicochemical characteristics.
Aims: We investigated the utility of this technique for the characterization of erythropoietic cell line and changes in the solubility of hemoglobin.
Methods: we used unstained BM smears of 24 normal BM and 8 megaloblastic anemia patients and unstained peripheral blood smears of 10 patients with sickle cell anemia. Images were captured by a confocal microscope with a HPM-100-40-Hybrid detector and excitation at 405 nm (diode laser,80 MHz). In order to create equivalent images of the cytological smears, pseudo-colors were attributed to different lifetime ranges. Images were compared with May-Grünwald-Giemsa (MGG) stained smears.
Results: FLIM created highly contrasted images, where different cell types could be easily recognized by their similarity with MGG images. Erythrocytes exhibited the shortest lifetimes (210.4±42.1 ps). Normal shaped erythrocytes in smears of sickle cell patients showed similar values (214.6±3.1 ps), whereas crenated erythrocytes as well as drepanocytes revealed significantly elevated values (314.2±66.7 ps and 312.5±67.0 ps respectively). Regarding erythropoiesis, the cytoplasm of erythroblasts showed significantly shorter lifetimes (623.5±271.2 ps) than that of myeloblasts (835.9±198.4 ps) and the same was the case when comparing the nuclei (erythroblasts: 895.4±262.8 *versus* myeloblasts: 1166.4±287.9 ps). The same differences could be found in megaloblastic anemias. There were no significant differences between the FLIM values of the different cell types between normal hemopoiesis and megaloblastic anemia.
Summary/Conclusions: The FLIM technique is easily applicable on unstained routine smears and revealed images of good quality permitting cell identification. It allowed also to distinguish between erythroid and myeloid precursors cells and indicates the major physico-chemical changes during the process of falcization.

TWO HEMATOLOGICAL MALIGNANCIES, SIMULTANEOUS OR CONSECUTIVE OCCURRENCE. EXPERIENCE OF A CENTER

E. Kapsali[1,*], A. Vassou[2], D. Gougopoulou[2], L. Kyriazopoulou[2],
E. Hatzimichael[2], I. Papakonstantinou[2], A. Serpanou[2], K. Lagos[2]
[1]Hematology, University of Ioannina, [2]Hematology, University of Ioannina, Ioannina, Greece

Background: Numerous reports of coexistence or consecutive occurrence of hematological malignancies are found in the literature.
Aims: : this study reports cases of patients with two hematological malignancies treated in a single center.
Methods: Retrospective study of patients with two malignancies occurring simultaneously or consecutively in patients in a hematology department during a 15 years period.
Results: Thirteen (13) cases were identified (5 women, 8 men). Their demographic characteristics, diagnoses, treatment and overall survival are shown

on Table 1.There are three deaths because of refractory diseases. Five patients needed treatment for the first disease and nine patients needed treatment for the second disease. Four patients had treatment for both diseases.

Table 1.

CLL:Chronic Lymphocytic Leukemia, MDS: myelodysplastic syndrome, CML: Chronic Myeloid Leukemia, PV: Polycythemia Vera, DLBCL: Diffuse Large B cell lymphoma, ET: essential thrombocytosis, CMML: Chronic Myelomonocytic Leukemia, FL: follicular lymphoma, HL: Hodgkin Lymphoma, SMZL: splenic marginal zone lymphoma, HCL: hairy cell leukemia, MGUS: monoclonal gammopathy of undermined significance

Summary/Conclusions: occurrence of two malignancies in the same patient can be a challenge for the hematologist. Findings of the second disease can be attributed to the fist disease or considering them to be results of treatment. Follow up and initiation of treatment in those patients can be more complex than usual. . As far as origin is concerned there are conflicting reports in the literature supporting a common or different cells of origin. Recording of these cases and biobanking can be of great interest for understanding mechanisms of hematologic neoplasms.

[1]Haematology Department, Hospital Universitari Joan XXIII, [2]Haematology Department., Hospital Universitari Joan XXIII., Tarragona, [3]Oncology Department, Hospital Universitari Sant Joan, Reus, [4]Haematology Department, Hospital Sant Pau i Santa Tecla, Tarragona, [5]Haematology Department, Hospital Verge de la Cinta, Tortosa, Spain

Background: The prognosis of Hodgkin lymphoma (HL) has improved significantly with the implementation of a risk-adapted treatment that combines chemo and radiotherapy. Altough this approach has led to the greatest advance in disease response, the benefit in terms of overall survival (OS) has been jeopardized by long term toxicity.
The identification of risk factors is crucial to assign each patient to a well defined risk group and prevent under or overtreatment, minimizing the risk of relapse and long term toxicity.
Aims: To analyze the risk factors associated with survival in HL treated with an ABVD based regimen that restricted radiotherapy only to bulky disease.
Methods: We retrospectively analyzed HL patients diagnosed in 4 centers in Tarragona area (Catalonia, Spain), between 1995 and 2015, treated uniformly according to a local protocol.
Patients were assigned into 4 groups: G1: favorable early stage: ABVDx6 cycles, G2: Bulky early stage without other risk factors: ABVDx6+IFRDT. G3: unfavorable early stage (B symptoms) and advanced stage without bulky disease: ABVDx8, G4: Bulky advanced stage: AVBDx8+IFRDT
Results: A total of 183 patients were analyzed with a median follow up of 82 months [range 1-244]. Male/female ratio was 1,29. Median age was 36 years [range 16-82]. Complete response was achieved in 160 patients (87,4%). The estimated OS at 20 years for the whole group was 62.7%. Kaplan–Meier method and log rank test were used for survival analysis. Cox proportional hazard model was used for univariate analysis to identify predictive factors for OS. Factors with significance ($p < 0.05$) were considered for multivariate Cox regression. In univariate analysis, worse OS was found in patients with increased LDH, non-NS subtype, albumin <3,5 g/dL, B symptoms, HIV+, advance stage and ESR >50 mm (log rank *p=0,012; p=0,049; p=0,024; p=0,002; p=0,005; p=0,004* and *p=0,001* respectively). The multivariate Cox regression analysis identified B symptoms and ESR >50 mm as independent prognostic factors for OS (*p=0,002*; *p=0,006* respectively). These variables allowed us to identify 3 patient groups: low (no risk factors), intermediate (either B symtoms or ESR>50 mm) and high risk (both risk factors), with significant differences in OS. Estimation for OS was uniformly analyzed at 216 months (18 years), which is the shortest follow up period for patients in the low risk group. Patients in the low, intermediate and high risk groups had an estimated OS of 85.7%, 65% and 40.1% (*p<0.001*) (Figure 1).

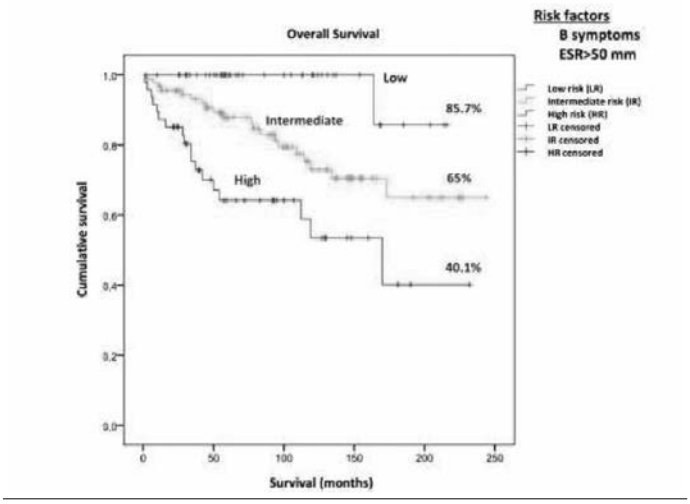

Figure 1.

Summary/Conclusions: B symptoms and ESR>50mm are independently associated with OS. The combination of these factors can stratify patients in low, intermediate and high risk groups with significant differences in OS, regardless their clinical stage.

PB1862

ADVANCED HODGKIN LYMPHOMA PATIENTS WITHOUT LARGE TUMOR MASS – A NEW PROGNOSTIC SCORE IDENTIFIES PATIENTS WITH FAVORABLE OUTCOME

B. Andjelic[1,*], D. Antic[1], L. Jakovic[1], M. Todorovic[1], J. Bila[1], V. Djurasinovic[1], V. Vukovic[1], A. Sretenovic[1], J. Jelicic[1], M. Smiljanic[1], B. Mihaljevic[1]
[1]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: ABVD and escalated BEACOPP are still the standard of care in patients with advanced Hodgkin Lymphoma (HL). The use of escalated BEACOPP gives better disease control but it is associated with more acute and late toxic effects. The identification of patients who require more or less aggressive initial approach remains the main goal for many investigators in the field of HL.
Aims: The aim of this study was to identify among patients with diagnosed advanced HL without large tumor mass, the subgroup which should not be considered for more aggressive approach than ABVD.
Methods: A retrospective study was performed on 149 patients classical HL, diagnosed in the period June 1997-December 2011. All the patients were in clinicil stage III or IV and didn't have any tumor lesion of 5 cm or more in its longest diameter. The standard of initial care was 6-8 cycles of ABVD followed by radiotherapy. Prognostic relevance of age more than 45 years, gender, CS IV, presence of B symptoms, IPS score, ESR≥50 mm/h, Hgb <10.5 g/dL, WBC≥15,000mm³ and lymphopenia (lymphocytes <600/mm³ or <8% of WBC count) were examined.
Results: The median age of analysed patients was 37 (range 17-80). The median follow up was 98 months. For the whole group 5-year event free survival (EFS) was 63.1% and 5-year overall survival (OS) was 80.6%. In univariate analysis, worse OS was found in patients older than 45 years (5-year OS 66.7% *vs* 87.8%), patients with CS IV (5-year OS 70.2% *vs* 87.0%), B symptoms (5-year OS 77.1% *vs* 93.4%), IPS≥3 (5-year OS 71.8% *vs* 90.1%), ESR≥50 mm/h (5-year OS 75.0% *vs* 89.5%), lymphopenia (5-year OS 65.6% *vs* 84.6%) (log rank; p=0.001, p=0.006, p=0.040, p=0.003, p=0.007, p=0.010, respectively), while gender, anaemia and leukocytosis didn't influence OS (log rank; p=0.303, p=0.714, p=0.522, respectively). Worse EFS was found in patients with CS IV (5-year EFS 50.9% *vs* 70.7%, kog rank p=0.002), IPS≥3 (5-year EFS 53.8% *vs*.73.2%, (log rank; p=0.006) and lymphopenia (5-year EFS 50.0% *vs* 66.7%, kog rank p=0.025), while age, gender, B symptoms, ESR≥50 mm/h, anemia and leukocytosis didn't influence EFS (log rank; p=0.0.078, p=0.437, p=0.068, p=0.151, p=0.384, p=0.158, respectively). The multivariate Cox regression analysis identified age more than 45 years, ESR≥50 mm/h and lymphopenia as independent prognostic factors for OS, while only IPS was identified as an independent factor for EFS. Afterwards, we performed survival analysis with aggregate scores of identified negative prognostic factors for OS for each patient. Since there was no difference in OS in intergroup analysis, groups with 2 and 3 negative prognostic factors were merged. Finally, we developed prognostic model for identifying patients at low (0 factors), intermediate (1 factor) and high risk (2-3 factors) for poor outcome (p=0.000). According to this model, in the examined group 34 (22.8%) patients had low, 64 (43.0%) intermediate and 51 (34.2%) high risk for poor outcome, with 5-years OS of 100%, 84.3% and 60.8%, respectively.
Summary/Conclusions: According to the score which we developed, ABVD is very effective in the subgroup of advanced HL patients without large tumor mass and without identified risk factors.

PB1863

TREATMENT ESCALATION IN CASE OF POSITIVE PET 2 AND IMPACT OF EARLY PET IN EXTENSIVE STAGE HODGKIN LYMPHOMA

S. Guidez[1,*], N. Moya[1], C. Gruchet[1], L. Perrichot[1], C. Tomowiak[1], T. Systchenko[1], A. Machet[1], X. Leleu[1], V. Delwail[1]
[1]Hématologie et Thérapie Cellulaire, CHU La Milétrie, Poitiers, France

Background: ABVD therapy has been for a long time the reference to advanced stage hodgkin lymphoma (LH). More recently, the emergence of more sustained dose / intensity regimens like BEACOPP has improved the progression-free survival of patients, in particular due to better initial control of the disease. The choice between these two regimens of treatment is always controversial in particular because of an immediate and delayed toxicity potentially increased after BEACOPP. With the use of PET-scanner, escalation and de-escalation protocols based on the PET response were studied. Recent studies have looked at the impact of the PET response to adapt the treatment: de-escalation after BEACOPP in case of a good response, escalation with more aggressive regimens after ABVD in positive PET.
Aims: We report here our experiment of escalation in case of positive PET after 2 cycles of ABVD (PET 2) in patients with advanced Hodgkin lymphoma.
Methods: Among the 102 patients with Hodgkin lymphoma treated between 2008 and 2016, 50 patients had advanced disease (Stage III or IV of Ann Arbor). The majority of patients were treated on front line by ABVD (47 patients), 2 by BEACOPP and 1 by VABEM. All patients underwent PET evaluation at diagnosis and after 2 cycles of treatment. The analysis of the metabolic response was carried out according to the Deauville criteria.
Results: The median age of the patients was 48 years (min-max: 19-85). 20 patients (40%) had an unfavorable prognosis, 24 (48%) had an intermediate prognosis. 11 patients (22%) were refractory to the ABVD protocol and had an escalation of treatment. The median PFS was 66 months (47-85). The median overall survival was not achieved; OS at 60 months was 65%. We found no difference in survival between patients with negative PET and those with positive PET with escalation of treatment. The study of PET 2 response, its impact on survival, as well as escalation of treatment will be presented to the EHA with update of follow-up.
Summary/Conclusions: This study evaluated the value of escalating treatment in patients with advanced PET 2 in patients with advanced Hodgkin lymphoma treated in first-line by ABVD. This management aims to reduce the toxicity of intensive treatments. The aim of our study is also to identify the higher risk patients for whom more intensive treatment could be used as first-line treatment.

PB1864

THE PROGNOSTIC IMPACT OF 18F-FDG PET/CT IN LYMPHOMA PATIENTS AFTER STANDARD CHEMOTHERAPY

K. Mladenov[1,*], B. Spassov[2], V. Hadzhiyska[1], D. Vassileva[3]
[1]Clinic of Nuclear Medicine, University Hospital "Alexandrovska", [2]Clinical Hematology, [3]Laboratory of nuclear medicine, SBALHZ, Sofia, Bulgaria

Background: The lymphomas are a heterogeneous group of malignant diseases. The exact diagnosis, precise staging and follow up is very important for treatment and prognosis of these patients (pts). Accurate pretreatment evaluation and response assessment are critical to the optimal management of lymphoma pts. Differentiation of post-therapeutic residual tissue from active lymphoma is unsatisfactory when using only morphological imaging approaches. Positron emission tomography/computed tomography (PET/CT) is the most sensitive and specific imaging technique for monitoring therapy response currently available for lymphoma pts after standard chemotherapy and determining which pts would benefit from additional treatment.
Aims: The aim of the study was to assess the clinical value of 18F-FDG PET/CT for staging and response evaluation in lymphoma pts with Hodgkin's disease (HD) and non-Hodgkin's lymphoma (NHL).
Methods: Two hundred and twenty six pts with biopsy proven lymphoma – (HD n=92 and NHL n= 134), aged 18-76, were retrospectively reviewed. These pts were examined 4-6 weeks after the completion of the standard chemotherapy by 18F-FDG PET/CT, according to the accepted protocol. PET/CT was used to assess response in FDG-avid histologies using 5-point scale, both for interim analysis and treatment end assessment. The Lugano classification has proved extremely useful in the standardization of treatment response. A score 1, 2, 3 is considered to represent complete metabolic response; score of 4, 5 – partial, no response or progressive disease.
Results: By applying PET/CT results two pts' groups were formed: 1.group (n=153 pts) with negative PET/CT results (Deauville score 1-3) and 2.group (n=73 pts) with PET/CT positive results (partial metabolic response or progressive disease). Using Deauville criteria complete response was observed in 95 patients (70.9%) NHL and 58 (63%) HD pts. These pts were in continuous complete remission. Partial response, stable or progressive disease (Deauville score 4-5) were detected in 39 (29.1%) and 34 (37%) NHL and HD pts, respectively. One hypermetabolic lesions and disseminated nodal or extranodal involvement were detected in 15 and 24 NHL pts as well in 12 and 22 HD pts. The pts with one hypermetabolic lesions were considered for radiotherapy, while pts with more than one nodal or extranodal lesions after completion of standard chemotherapy were considered for high dose chemotherapy±autologous stem cell transplantation (ASCT).
Summary/Conclusions: 18F-FDG PET was useful in HD and NHL pts after standard chemotherapy not only for determination of those who need additional therapy, but for the choice of the further management: radiotherapy, chemotherapy, or ASCT. A negative PET/CT study after the completion of therapy is an excellent predictor of good prognosis.

PB1865

BCL-2 AND CD30 EXPRESSION IN HODGKIN AND REED-STERNBERG CELLS OF CLASSICAL HODGKIN'S LYMPHOMA AS A POORER PROGNOSIS CRITERIA

A. Rukavitcyn[1,*], A. Bobin[1], M. Pecherskaya[1], O. Rukavitcyn[1]
[1]Main military hospital named by N.N. Burdenko, Moscow, Russian Federation

Background: There are a lot of prognosis criteria for risk stratification of Hodgkin's lymphoma (HL). The most applicable is the IPS-7, however this score is ignoring a tumor cells phenotype. There are data about dependence survival and antigenic profile of Reed-Sternberg (RS) cells. To determine the clinical significance of bcl-2 and CD30 expression in RS cells of classical HL, we have correlated it's expression with available IPS criteria and failure-free survival (FFS) after treatment by ABVD (adriamicyn, bleomicyn, vinblastine, dacarbazine).
Aims: To determine predictive possibility proapoptotic protein bcl-2 and CD30 antigen on RS cells aggregating with criteria IPS.

Methods: In study were included 85 previously untreated patients, presented with classical HL between 2002 and January 2016. This retrospective study did not require approval by the Local ethical committee. Inclusion criteria were: a histologically confirmed diagnosis of classical HL, the presence of a fixed in paraffin before treatment a lymph node sample or other diseased tissue, the minimum follow-up was not less than 18 months.
Results: In the study population (n=85) identified 30 (35%) histological samples bcl-2+, and 55 biopsies (65%), bcl-2. Group bcl-2+ patients had a lower response rate after ABVD chemotherapy - only 24 (28%) patients achieved CR or better result, as compared with 49 patients (57.6%) of the bcl-2 group. Three-year event-free survival (EFS) in bcl-2+ patients had lower 82% *vs* 96% than in bcl-2 group (p=0.018). Multivariate analysis using the Cox proportional hazard model with the inclusion of bcl-2+; CD30 +; bcl-2+/ CD30 +, age 45 and older, B-symptoms, III-IV stage, anemia, decreased serum albumin, increased LDH, leukocytosis revealed that the expression of bcl-2 on RS cells was an independent factor of poor prognosis. 3 year EFS was 52% *vs* 90% in bcl-2 population (p=0.022; RR=1,4). The greater relative risk was observed in a population with double expression of bcl-2 and CD30, where the 3-year EFS was 47% (p=0.012; RR=1,6).
Summary/Conclusions: The expression of bcl-2 on HRS cells can be an independent prognostic factor, co-expression of bcl-2 and CD30 can be viewed as a more powerful factor of poor prognosis than bcl-2+ cells.

PB1866

SURVIVAL ANALYSIS OF PATIENTS WITH CLASSICAL HODGKIN'S LYMPHOMA TREATED WITH ABVD: RESULTS FROM TWO REFERRAL CENTERS IN MEXICO CITY.

G.P. Agreda-Vásquez[1], A. F. Ramírez-Ibarguen[2], E. Crespo-Solís[3,*], M.S. Rivas-Vera[2]
[1]Department of Hematology and Oncology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, [2]Department of Hematology, Instituto Nacional de Cancerología, Mexico City, [3]Department of Hematology and Oncology, Hospital Regional de Alta Especialidad de Ciudad Victoria, Victoria, Mexico

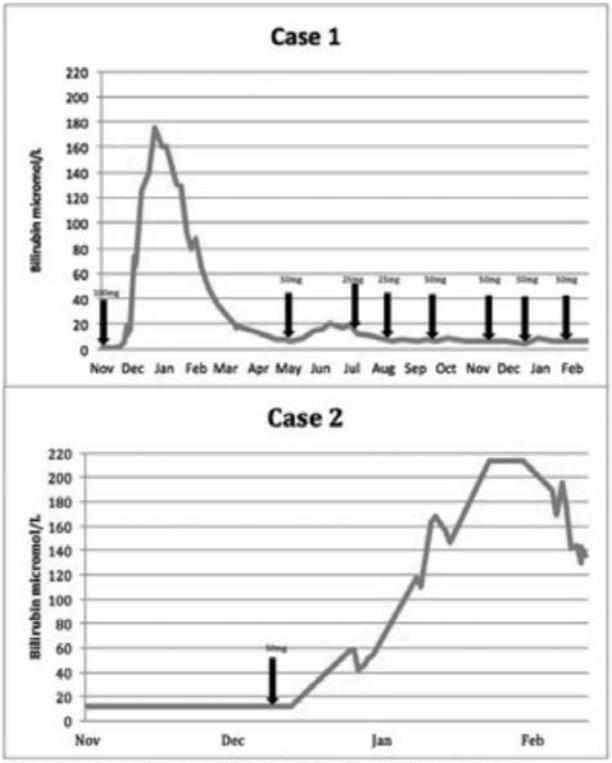
Background: Classical Hodgkin´s lymphoma (cHL) is a neoplastic disease with a favorable prognosis since 85% of patients can be considered cured with current treatment strategies. Combined chemotherapy with Adriamycin, Bleomycin, Vinblastine and Dacarbazine (ABVD) has been the standard therapy for over 20 years. Epidemiological information and the regimen´s results as first-line therapy in Mexico are limited.
Aims: The aim of this study was to conduct a survival analysis in adult patients from two referral centers in Mexico City.
Methods: This is a retrospective analysis of all patients with cHL treated at the Instituto Nacional de Cancerología and the Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, between 2009 and 2013. The study was approved by the local Ethics Committee.
Results: We included a total of 193 patients with a *de novo* diagnosis and initially treated with ABVD: 60.6% of cases were male, with a median age of 36 years (17-81 years), 71.5% were diagnosed in late clinical stages (CS). The most frequent histopathological subtypes were: nodular sclerosis and mixed cellularity (46.6% and 40.9%; respectively). The observed overall response rate (RR) was 85.7% [Complete response (CR) was 78.2%]. The RR was 90% in early CS *vs* 83.8% in late CS (CR rate was 84% *vs* 75.8%; respectively, *p*=0.23). Univariate analysis by logistic regression in the early CS group revealed that having a Lymphocyte:Monocyte ratio <1 presents an unfavorable tendency to achieve CR [OR 0.150 (95%CI 0.018-1.274; *p*=0.082)]. In the group in late CS, we found that the lymphocyte percentage tended to favor CR [OR 1.048 (95%CI 0.994-1.105; *p*=0.081)] and the opposite was observed in terms of the absolute monocyte count [OR 0.999 (95%CI 0.998-1.000; *p*=0.082)]. Median follow-up was 35 months (0-96 months), 10.9% of cases had died at last follow-up, and median overall survival (OS) of the entire cohort had not been reached at the time of analysis (5-year OS, 87.1%). However, at the time of this analysis, the group of patients in complete remission had a greater OS than the group that did not achieve CR (*p*=0.0001). With Cox multivariate analysis of OS according to CS, we detected that in the group in early CS, none of the analyzed factors were significant while in the late CS group, age >45 years was an independent risk factor [HR 6.9 (95%CI 1.80-26.60; *p*=0.005)] and achieving CR had a protective effect [HR 0.02 (95%CI 0.004-0.108; *p*=0.0001)].
Summary/Conclusions: Although OS medians had not been reached at the time of analysis, it is noteworthy that CR (84%) in early CS is lower than that reported in the literature and no related prognostic factor has been identified. The role of lymphocytes and monocytes may prove to be significant in larger series with a longer follow-up.

PB1867

OUTCOME OF PD-1 BLOCKADE IN PATIENTS WITH RELAPSED HODGKIN LYMPHOMA AND ACTIVE GRAFT-*VERSUS*-HOST DISEASE

A. Minson[1,*], G. Douglas[1], A. Grigg[1]
[1]Haematology, Austin Health, Heidelberg, Australia

Background: Efficacy of PD-1 (programmed death-1) inhibitors in relapsed/refractory Hodgkin lymphoma (HL) has been established, but their role in relapse after allogeneic stem cell transplant (alloSCT) remains controversial due to the perceived risk of exacerbating graft-*versus*-host disease (GVHD). The literature is largely limited to case reports in patients with no or quiescent GVHD.
Aims: To describe the outcome of PD-1 inhibitor therapy and subsequent management in patients with concomitant biopsy proven active GVHD and progressive HL after alloSCT.
Methods: We describe the treatment and management of two patients in our centre.
Results: Case 1 had both extensive bony, lung and nodal HL with active skin, pleuropericardial and liver GVHD 6 months after donor leucocyte infusion (DLI) and immunosuppression withdrawal and 24 months after sibling alloHSCT. Fifty% of the standard pembrolizumab dose (100mg) produced a PET partial response after 5 weeks but with concomitant biopsy proven, severe exacerbation of liver GHVD. The latter was managed with prednisolone, everolimus, ursodeoxycholic acid (UDCA) and subsequently tacrolimus with gradual but substantial improvement in liver function over the next 5 months (Figure 1) in the absence of further PD-1 blockade, but with progression of lymphoma. Pembrolizumab 50mg was then given with lymphoma response but again a significant (but less severe) flare of liver GVHD occurred. Subsequent 25mg doses failed to prevent lymphoma progression. Reintroduction of 50mg doses approximately each 6 weeks for 4 doses with prophylactic everolimus, low dose prednisolone and ruxolitinib, has resulted in ongoing substantial but incomplete PET responses with associated stable liver GHVD. Case 2 had progressive mediastinal and pulmonary HL despite DLI-induced extensive liver and skin chronic GVHD 38 months post sibling alloSCT. Initial therapy consisted of optimisation of liver GVHD with 8 weeks of UDCA and prednisolone with improvement in liver indices (Figure 1). Pembrolizumab 50mg was then given, together with sirolimus and ruxolitinib as GVHD 'prophylaxis', resulting 5 weeks later in complete metabolic remission on PET. Concomitantly liver GVHD was aggravated (See Figure 1) together with pancytopenia and marrow hypoplasia attributed to an immune-mediated phenomenon. Despite addition of tacrolimus and increased steroids, he remains with severe liver dysfunction and pancytopenia 10 weeks after the single dose of PD1 inhibitor therapy.



Bilirubin level as a marker of liver GVHD, with relationship to pembrolizumab dosing. Arrows denote time-points and doses of pembrolizumab given.

Figure 1.

Summary/Conclusions: PD-1 inhibitors can exert powerful graft *vs* HL effects even in patients with progression in the context of active GVHD, but at the expense of substantial GVHD exacerbation. Further exploration of approaches such as individualised dose titration according to response and GVHD activity and prophylactic therapy with non-calcineurin based immunosuppression which may not mitigate the anti-lymphoma effect will help evaluate whether durable responses with tolerable toxicity is possible in this context.

PB1868

PROGNOSTIC VALUE OF THE RED CELL DISTRIBUTION WIDTH IN PATIENTS WITH CLASSIC HODGKIN LYMPHOMA

A. Knezović[1], V. Periša[2,3,*], L. Zibar[4], J. Sinčić-Petričvić[2]
[1]Comunity Health Centre Đakovo, Faculty of Medicine, University of Osijek, Osijek, Croatia, Đakovo, [2]Hematology, University Hospital Centre Osijek, [3]Department for Pathophysiology, Faculty of Medicine, University of Osijek, Osijek, Croatia, [4]Nephrology, Department for Pathophysiology, University Hospital Centre Osijek, Faculty of Medicine, University of Osijek, Osijek, Croatia, Osijek, Croatia

Background: The current gold standard for risk stratification in Hodgkin lymphoma (HL) is the International Prognostic Score. There are certain molecular and immunohistochemical prognostic markers in patients with HL, but their cost and technical constraints make such an application in routine impractical and expensive. Therefore, prognostic models for classic HL (cHL) that are inexpensive, simple, and easy to perform and interpret are needed.
The red blood cell distribution width (RDW) is associated with short- and long-term outcomes of various malignancies. The prognostic value of the RDW in cHL remains unknown.
Aims: The aim of this study was to analyze the prognostic significance of RDW in cHL patients.
Methods: We retrospectively analyzed data from 54 cHL patients diagnosed from 2005 to 2016 at the University Hospital Center Osijek, Osijek, Croatia. We evaluated disease outcome, overall survival (OS) and event-free survival (EFS), and demographic, clinical and laboratory factors affecting outcome. Univariate analysis and Cox regression analysis were used.
Results: The median age of patients was 36 years, 29 were men (54%). Higher RDW levels (%) were found in patients with advanced Ann Arbor clinical stage (15.34 ± 2.28 *vs* 13.12 ± 1.3, $P < 0.001$) and in those with poor response to therapy (15.65 ± 3.37 (progression) *vs* 16.68 ± 2.09 (partial remission), 13.95±1.82 (complete remission), $P = 0.008$). Patients with RDW values of >14.5% (cutoff value calculated by receiver-operating characteristic) had a significantly worse two-year EFS (62.4% *vs* 90.4%, P=0.009) but did not differ significantly in terms of OS (P=0.2). Univariate analysis revealed that a high RDW (>14.5) was correlated with poor EFS (P=0.019). Multivariate Cox regression analysis showed that RDW >14.5% was an independent prognostic factor for EFS (hazard ratio [HR] 3.801, 95% confidence interval [CI] 1-14.45, P=0.05). The RDW allowed further borderline statistically significant risk stratification in patients who were considered to be at low risk on the basis of an International Prognostic Score less than 4 (P=0.053).
Summary/Conclusions: High baseline RDW is an independent prognostic marker of poor outcome in patients with cHL. RDW ratio is asimple, inexpensive, and independent prognostic factor for EFS that may improve the ability to identify high-risk patients with cHL. It could be an easily available and inexpensive marker for the risk stratification in patients with cHL.

Indolent Non-Hodgkin lymphoma – Clinical

HIGH FREQUENCY OF SECONDARY MALIGNANCIES IN PATIENTS WITH LARGE GRANULAR LYMPHOCYTIC LEUKEMIA: A SINGLE INSTITUTIONAL EXPERIENCE

L. Isenalumhe[1,*], M. Van den Bergh [1], E. Wang[2], B. Schaible[1], Z. Ma[1], L. Zhang[1], L. Sokol[1]
[1]Hematology-Oncology, H. Lee Moffitt Cancer Center and Research Institute, [2]Internal Medicine, University of South Florida, Tampa, United States

Background: Large granular lymphocyte (LGL) disorders represent a spectrum of aberrant T-cell or natural killer cell lymphocytic proliferations. LGLL is classically associated with autoimmune conditions and bone marrow (BM) failure disorders. SM has been reported in association with LGLL in about 10%.
Aims: The aim of this study is to evaluate the impact of SM on the clinical course of LGLL
Methods: This is a retrospective study of LGLL patients evaluated at Moffitt Cancer Center between January 1995 and May 2016. The diagnostic clinicopathological criteria consisted of LGL count > 0.5 k/μL with T-cell receptor gene rearrangement. Lower absolute number of clonal circulating LGLs with characteristic immunophenotype associated with BM involvement, cytopenias, splenomegaly and/or associated symptoms were also diagnostic. Patients with myelodysplastic syndrome were excluded. Survival analysis was performed using the Kaplan-Meier method with log-rank test. Chi-square and T-test were used to analyze association among various variables. Significant P-value was considered < 0.05.
Results: Out of 668 screened patients with LGL expansions in peripheral blood, 261 met criteria for LGLL. Secondary malignancies were present in 44% (116/261) of LGLL patients, of which 38% were hematological and 80% arose prior to onset of LGLL. Most common solid secondary malignancy included skin cancer (14%), prostate cancer (12%), and breast cancer (12%), while most common hematological secondary malignancy consisted of non-Hodgkin lymphoma (17%) and chronic leukemia (14%). 5-year overall survival (OS) for all LGLL patients was 75% and 10-year OS 63%. There was a statistically significant difference in 5-year OS between LGLL patients with a secondary malignancy compared to without (p = 0.049), but no difference between both groups in median OS or 10-year OS. Patients diagnosed with a secondary malignancy prior to LGLL had worse 5-year OS (p = 0.031) and 10-year OS (p = 0.05) compared to all other LGLL patients.
Summary/Conclusions: This study showed that the frequency of a secondary malignancy is higher than previously described, especially with onset prior to diagnosis of LGLL. Even though median age of LGLL is around 60 years, it appears that age itself cannot explain this phenomenon. Our results suggest that having a secondary malignancy is a poor prognostic factor in LGLL patients.

BENDAMUSTINE AND RITUXIMAB COMBINATION THERAPY WITH SUBSEQUENT RITUXIMAB SUPPORTING THERAPY IN RUSSIAN SUBJECTS WITH RELAPSED OR REFRACTORY INDOLENT B-CELL NON-HODGKIN LYMPHOMAS

I. Poddubnaya[1,*], L. Babicheva[1], V. Melnichenko[2], E. Volodicheva[3], E. Kuznetsova[4], N. Tyurina[5], K. Kaplanov[6], T. Kaporskaya[7], D. Olkin[8], N. Domnikova[9], V. Bakhtina[10], V. Mladov[11], K. Kanhai[12]
[1]Russian Medical Academy for Postgraduate Education of Ministry of Health, [2]Scientific Medical Surgical Center n.a.I.V.Pyrogov, Moscow, [3]Regional Clinical Hospital, Tula, [4]Regional Clinical Hospital, Orenberg, [5]Moscow Scientific Research Oncology Institution n.a.P.A. Gertzen, Moscow, [6]Volgograd Regional Clinical Oncology Dispensary#1, Volgograd, [7]Regional Clinical Hospital, Irkutsk, [8]Atlas Medical Center, Moscow, [9]Novosibirsk State Regional Clinical Hospital, Novosibirsk, [10]Regional Clinical Hospital, Krasnoyarsk, [11]Clinical Trial Support, Smolensk, Russian Federation, [12]Astellas Pharma Europe, Middle East and Africa, Chertsey, United Kingdom

Background: Combination of bendamustine and rituximab has been established in many international guidelines as treatment for patients with indolent B-cell non-Hodgkin lymphoma (iNHL).
Aims: Objectives of this study were to evaluate the effectiveness, safety, and tolerability of bendamustine/rituximab combination followed by rituximab maintenance therapy for relapsed or refractory (R/R) iNHL patients in the Russian Federation.
Methods: Adult subjects (≥18 yr), diagnosed with R/R iNHL according to local diagnostic standards, and were enrolled in this prospective observational study. Intravenous therapy was administered in 2 stages (Figure 1): a combination therapy stage followed by a rituximab supporting therapy stage for subjects who achieved complete response (CR) or partial response (PR) during the combination therapy stage. Overall response rate (ORR) was assessed after

3 (Evaluation 1) and 6–8 (Evaluation 2) 28-day cycles. Data from the full analysis set (FAS) were used for the primary analysis and the per-protocol (PP) set for a subgroup analysis. Safety/tolerability was a secondary endpoint and was assessed in the safety analysis set (SAF). Response assessments used the LOCF method for substitution of missing data; overall survival (OS) and progression-free survival (PFS) were calculated using Kaplan–Meier estimates, safety/tolerability was assessed by adverse event (AE) frequency and described using descriptive statistics.

Results: Of the 102 subjects enrolled between June 2012 and October 2015, 83 subjects (52M/31F; median age 59 yr [range: 27–84]) with various NHL histology; subjects with mantle cell lymphoma [n=4], diffuse large B-cell lymphoma [n=2], and follicular lymphoma transformation [n=1] were excluded from the PP population due to deviation from the iNHL inclusion criteria. Most study subjects were heavily pretreated with a median number of 2 prior lines of therapy before entering the study (range: 1–6). At Evaluation 2, ORR in the FAS was high (n=58; 69.9%) with 35 (42.2%) subjects achieving CR (confirmed, n=20 [24.1%]; unconfirmed, n=15 [18.1%]) and 23 (27.7%) achieving PR; ORR (defined as [CR+CR unconfirmed +PR]) in the PP population was 70.8% (Table 1). For FAS patients, at follow up (17 mo) neither median OS nor PFS had been reached; 2-year OS was 88.9% (95% CI: 79.7–99.0%) and 2-year PFS was 87.9% (95% CI: 80.7–95.7%). In the SAF, 31 of 96 subjects (32.3%) reported ≥1 AE. Decreased neutrophil count, decreased white blood cell count, and infections were the most commonly reported AEs and serious AEs. Twelve deaths occurred: 5 due to disease progression (n=2) or relapse (n=3), 5 were not related to lymphoma or occurred during remission, 1 cause of death was unknown, and 1 subject died from hyperthermia and respiratory failure, which was the only death in the study considered related to combination therapy.

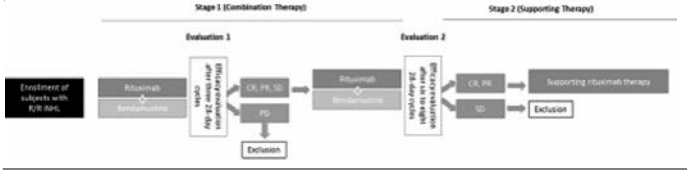

Figure 1.

Table 1.

	FAS Population (n=81)		PP Population (n=72)	
	Evaluation 1	Evaluation 2	Evaluation 1	Evaluation 2
ORR, n (%)	56 (67.5)	58 (69.9)	49 (68.1)	51 (70.8)
CR/CRu	24 (28.9)	35 (42.2)	22 (30.6)	33 (45.8)
PR	32 (38.6)	23 (27.7)	27 (37.5)	18 (25.0)

Summary/Conclusions: Bendamustine plus rituximab therapy followed by rituximab maintenance therapy was generally well tolerated and demonstrated clinical effectiveness in Russian R/R patients with iNHLs. Although a number of subjects with aggressive lymphomas were included in the FAS, the ORR rate was not considerably different from the PP population (ORR: 69.9% [FAS] *vs* 70.8% [PP]).

PB1871

PROGNOSTIC VALUE OF G8 SCREENING TOOL IN PATIENTS WITH NDOLENT B-CELL LYMPHOPROLIFERATIVE NEOPLASMS – A SINGLE CENTRE EXPERIENCE

Z. Cvetkovic[1,2,*], A. Novkovic[1], Z. Djumic[3], T. Bibic[1], A. Ivanovic[1], N. Milutinovic[1]
[1]Department of haematology, Clinical Hospital Center Zemun, [2]Medical Faculty University of Belgrade, Belgrade, Serbia, [3]Department of haematology, Medical Faculty University of Belgrade, Belgrade, Serbia

Background: Indolent B-cell lymphoproliferative neoplasms (B-LPN) are malignant diseases of advanced age. The most common among them, follicular lymphoma (FL), marginal zone lymphoma (MZL) and chronic lymphocytic leukemia (CLL) together represent about 40% of all B-LPN. However, as indolent B-LPN are most often the slow-growing diseases, an approach "watch and wait" is often recommended. But, when treatment is necessary, the advanced patients' age indicate the need for geriatric assessment (GA) in aim to indentify functional, cognitive, social, nutritional and psychological parameters of the general health status. G8 screening tool (G8) is recognized as fast, easy to perform and sensitive test for selecting the group of fit elderly patients capable for curative treatment approach. Although incorporated in routine oncological practice, GA and G8 are not widely evaluated in hematological practice, so far.
Aims: To evaluate the impact of G8 screening tool on clinical outcome and survival of elderly patients with indolent B-LPN s'> The most common among them, follicular lymphoma (FL), marginal zone lymphoma (MZL) and chronic lymphocytic leukemia (CLL) together represent about 40% of all B-LPN. However, as indolent B-LPN are most often the slow-growing diseases, an approach "watch and wait" is often recommended. But, when treatment is necessary, the advanced patients' age indicate the need for geriatric assessment (GA) in aim to indentify functional, cognitive, social, nutritional and psychological parameters of the general health status. G8 screening tool (G8) is recognized as fast, easy to perform and sensitive test for selecting the group of fit elderly patients capable for curative treatment approach. Although incorporated in routine oncological practice, GA and G8 are not widely evaluated in hematological practice, so far.
Methods: Total of 89 consecutive elderly patients (45males and 44 females with median age at diagnosis 74,6 years, range 65-88 years) with indolent B-LPN (24 with FL, 26 with MZL and 39 with CLL) who fulfilled criteria for treatment initiation were included in study. Patients were treated with antracycline, fludarabine or alkylated agents based chemotherapy regimens +/- monoclonal anti-CD20 antibody. Validity of G8 was compared with standard relevant clinical and laboratory parameters.
MZL) and chronic lymphocytic leukemia (CLL) together represent about 40% of all B-LPN. However, as indolent B-LPN are most often the slow-growing diseases, an approach "watch and wait" is often recommended. But, when treatment is necessary, the advanced patients' age indicate the need for geriatric assessment (GA) in aim to indentify functional, cognitive, social, nutritional and psychological parameters of the general health status. G8 screening tool (G8) is recognized as fast, easy to perform and sensitive test for selecting the group of fit elderly patients capable for curative treatment approach. Although incorporated in routine oncological practice, GA and G8 are not widely evaluated in hematological practice, so far.
Results: For all 89 patients median overall survival (OS) was 77 months, and disease free survival (DFS) in 58 (77.3%) patients achieving remission was 25 months. Among laboratory paremeters, hemoglobin, platelet, neutrophil and monocyte count, as well as C-reactive protein, beta-2 microglobulin didn't influence CR rate, OS and DFS. Elevated lactate dehydrogense was foud significante for CR rate, and low albumin level (<40g/L) for predicting OS. Among clinical parameters age, sex, presence of "B" symptoms, splenomegaly (>13cm), bulky disease (>10cm), extranodal (EN) disease, as well Charlson comorbidity index (CCI; ≤3/>3), ECOG performance status (PS; <2/≥2) and G8 screening tool (>14/≤14) were evaluated. EN and G8 were found significant for CR rate: and EN, B symptoms, ECOG PS and G8 for OS. Multiplarameter analysis singled out G8 as most sensitive prognostic parameter for both CR (P=0.005;HR 1,343, 95%CI:0.214-2.552) and OS (p=0.018; HR 11,262, 95%CI:1.503-4.400)
Summary/Conclusions: According to our experience, the implementation of G8 is good prognostic parameter. Its incorporation into standard hematological indices may help in improving the optimal treatment approach decision in elderly patients.

A PROSPECTIVE PHASE 2 TRIAL EVALUATING MONOTHERAPY WITH OFATUMUMAB FOR RELAPSED/REFRACTORY SPLENIC B-CELL MARGINAL ZONE LYMPHOMA (MORE TRIAL): SAFETY ANALYSIS RESULTS

L. Scarfo'[1,2,3,*], G. Gritti[4], A. Tedeschi[5], P. Ranghetti[1], C. Scielzo[1], P. Angelillo[1,2], M. Ponzoni[3,6], P. Ronchi[7], A. Ferreri[8], P. Ghia[1,2,3]
[1]B-cell Neoplasia Unit, IRCCS San Raffaele Scientific Institute, [2]Strategic Research Program on CLL, IRCCS Ospedale San Raffaele, [3]Università Vita-Salute San Raffaele, Milano, [4]Hematology and Bone Marrow Transplant Unit, Ospedale Papa Giovanni XXIII, Bergamo, [5]Department of Hematology, Niguarda Cancer Center, Niguarda Hospital, [6]Pathology Unit, [7]Immunohematology and Transfusion Medicine Service, [8]Unit of Lymphoid Malignancies, Department of Onco-Hematology, IRCCS San Raffaele Scientific Institute, Milano, Italy

Background: Due to the lack of prospective clinical trials, treatment guidelines for splenic marginal zone lymphoma (SMZL) are mainly based on single-center expertise. Treatment options for progressive disease include splenectomy, chemo-immunotherapy, or anti-viral therapy in HCV-positive cases. As SMZL cells strongly express CD20 molecule, rituximab has been used in patients unfit for chemotherapy or splenectomy with high response rates. Ofatumumab is a fully humanized, high-affinity anti-CD20 monoclonal antibody able to induce a more potent complement-dependent cytotoxicity if compared to rituximab. We designed this multicenter, open-label, single-arm phase 2 trial addressing activity and safety of ofatumumab monotherapy in patients with relapsed/refractory (R/R) SMZL.
Aims: The primary objective is the activity of ofatumumab in terms of complete response (CR) rate. Secondary objectives aim at evaluating the safety and tolerability and exploratory endpoints investigate biological features potentially related with response to ofatumumab.
Methods: All patients provided written informed consent. Key eligibility criteria include R/R disease after ≤2 prior line(s) of chemotherapy or immunochemotherapy (including single-agent rituximab). Patients are treated with ofatumumab (1st dose: 300 mg, 2nd-8th doses: 1000 mg) up to 8 weekly doses. Response assessment is scheduled 3 months after the last dose. Sample size was defined assuming a P0 of 45% CR, and a P1 of 65% CR. Per Simon optimal Two-Stage design (type I error=0.05, power=80%), 43 patients should be recruited. A safety analysis was planned after the enrollment of the first 10 patients. With an expected rate of adverse events (AEs) of 13%, if less than 3 AEs leading to withdrawal from treatment are reported, the accrual will

continue to the planned 15 patients (interim analysis). Here we present safety analysis results.
Results: Ten patients (6 males, 4 females; median age: 69.5 years, 9 ≥65 years, 1 <65 years) were analyzed for safety. Eight patients were previously treated with rituximab. 26 adverse events (AEs) occurred in 7 patients, with only 5 grade 3-4 AEs. Ten AEs were drug-related, 30% were of grade 3 (Table 1). Three SAEs occurred: hypersensitivity, n=2, both related, and dyspnea, n=1, unrelated to study drug. No AEs leading to treatment withdrawal was reported and no patients died on study. Hematological and biochemical abnormalities included: neutropenia (any grade 6 cases, grade 3-4: 4), thrombocytopenia (grade 1-2: 3 cases), lymphopenia (grade 1-2: 2 cases), leukopenia (grade 1-2: 5 cases), 1 case of GGT increase (grade 3, at baseline grade 2), 6 cases of ALP increase (all grade 1-2), 1 case each of AST, ALT and bilirubin increase (all grade 1). Preliminary response assessment in these 10 patients documented 5 CR, 4 Partial Responses (PR) and one patient with progressive disease (PD) at the end of treatment.

Table 1: List of AEs.

Drug-related AEs	N of events (any grade/grade 3-4)	Non-drug related AEs	N of events (any grade/grade 3-4)
Neutropenia	2 (2)	Neutropenia	1 (1)
Flushing	2 (0)	Anemia	1 (1)
Hypersensitivity	3 (1)	Neoplasm of nasopharynx	1 (1)
Throat irritation	1 (0)	Fatigue	2 (0)
Post herpetic neuralgia	1 (0)	Dyspnea, orthopnea	2 (0)
Hypertension	1 (0)	Pleural effusion, pulmonary failure	3 (0)
		Bone pain	2 (0)
		Constipation	1 (0)
		Oral herpes	1 (0)
		Pelvic pain	1 (0)
		Atrial fibrillation	1 (0)

Summary/Conclusions: Ofatumumab is safe and generally well-tolerated even in elderly patients with R/R SMZL. No cases of unexpected adverse drug reactions were documented. In a series of patients largely pre-treated with rituximab, ofatumumab resulted in a 90% overall response rate, 50% being CR. Complete results of the interim analysis will be presented at meeting.

PB1873

TREATMENT PATTERNS AND TREATMENT RESPONSE IN PATIENTS WITH FOLLICULAR LYMPHOMA IN ROUTINE CLINICAL CARE – A UNITED STATES ELECTRONIC MEDICAL RECORD DATABASE STUDY

A. Galaznik[1,*], J. Bell[1], L. Hamilton[2], A. Ogbonnaya[2], K. Hennenfent[2], M. Eaddy[2], Y. Shou[2]
[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [2]Xcenda LLC, Palm Harbor, United States

Background: FL represents 70% of all indolent non-Hodgkin lymphomas, and it is widely recognized that FL is a heterogeneous disease, with patients presenting with differing amounts of tumor burden and prognostic indicators. The NCCN guideline recommends using rituximab as a single agent or in combination with other chemotherapies as first-line therapy (1LT) or second-line therapy (2LT). No recommendations are provided beyond 2LT.
Aims: To evaluate treatment patterns and associated response in patients with newly diagnosed FL in routine care in the US.
Methods: Newly diagnosed FL patients aged ≥18 years were selected from Humedica, a large, national US EMR database, between 01/01/08 and 07/31/15 if they had ≥1 inpatient record or ≥2 outpatient records with FL diagnosis codes. The date of the first FL record was the index date. Patients were followed from index until end of continuous activity, progression to diffuse large B-cell lymphoma (DLBCL), death, or end of study period (09/30/15) and were evaluated for FL treatment patterns and treatment response. Possible remission was defined as no additional chemotherapy and no supportive care use or receipt of supportive care <30 days after end of line of therapy (LOT) for <30 days. Lack of remission was defined as receipt of supportive care <30 days after end of LOT for >30 days. Progression was defined as initiation of another LOT, transition to DLBCL, or evidence of supportive care >30 days after end of LOT.
Results: Of the 3,756 patients selected into the study, 1,346 (35.8%) initiated 1LT, and median (interquartile range [IQR]) time to therapy was 1.3 (0.5–5.9) months. Overall, treatment regimens were mainly rituximab-based. In 1LT, more patients initiated combination chemotherapy (61.4%) *vs* single-agent chemotherapy (38.6%). Bendamustine+rituximab (26.9%) and R-CHOP (15.1%) were the most common combination regimens, and rituximab (33.1%) was the most common single agent. Median (IQR) duration of 1LT was 4.3 (1.7–10.4) months. At the end of 1LT, 54.7% (n=736) had evidence of remission, 25.5% (n=344) progressed, and 1.6% (n=22) had no evidence of remission. Among patients with progression after 1LT, 201 initiated 2LT; 34.3% received a single agent, and 65.7% received combination chemotherapy. 2LT regimens were similar to 1LT, with rituximab (18.9%) remaining the top single agent, while bendamustine+rituximab (25.9%) and R-CHOP (6.0%) remained the top combinations. Median (IQR) duration of 2LT was 3.6 (1.4–6.1) months. Of patients receiving 2LT, 41.3% (n=83) had evidence of remission, 35.4% (n=71) progressed, and 1.5% (n=3) had no evidence of remission. 45 patients who progressed after 2LT received third-line therapy (3LT); 35.6% received a single agent, while 64.4% received combination chemotherapy. In 3LT, rituximab (11.1%) was the most common single agent; bendamustine+rituximab (20.0%) and cyclophosphamide+rituximab+vincristine (8.9%) were the most common combinations. Median (IQR) duration of 3LT was 2.8 (1.4–4.7) months. Following 3LT, 26.7% (n=12) had evidence of remission, 39.9% (n=18) progressed, and 4.4% (n=2) had no evidence of remission.
Summary/Conclusions: FL treatment in routine clinical care aligns with treatment guidelines in 1LT and 2LT, with most patients receiving rituximab-based combination chemotherapy. Similar regimens were used in the 3LT setting. As expected, the rates of remission decreased with subsequent LOTs.

PB1874

PET-CT AND BONE MARROW BIOPSY IN STAGING FOLICULAR LYMPHOMA IN A SINGLE INSTITUTION

I. Parraga[1,*], E. Gimeno [1], F. García Pallerols[1], B. Sanchez Gonzalez[1], M. Suarez[2], A. Mestre[2], M. Ferraro[1], E. Abella[1], L. Martinez[1], C. Pedro[1], E. Torres [1], J. Maiques[3], L. Colomo[4], C. Besses[1], A. Salar[1]
[1]Hematology department, Hospital del mar, Barcelona. Grup de recerca aplicada en Hematologia PSMAR, [2]Nuclear Radiology department, [3]Radiology department , [4]Pathology department , Hospital del Mar, Barcelona, Spain

Background: Follicular lymphoma (FL) is an indolent lymphoid B neoplasm corresponding to 20-25% of non-Hodgkin lymphomas (NHL). Bone marrow biopsy (BMB) is part of standard work-up in indolent NHL since up to 40-70% of cases have bone marrow infiltration. This fact is important, so advance stage is one factor considered in the FLIPI-1 and FLIPI-2 prognostic index. Positron emission tomography/computed tomography (PET-CT) is a noninvasive technique that shows high sensitivity of detecting nodal and extranodal lymphoma involvement. specially in aggressive subtypes. Some studies have described a high sensitivity (62-100%) and specificity (96-100%) in the detection of bone marrow involvement in agressive NHL. However, its role in low-grade indolent lymphoma such as folicular lymphoma remains controversial.
Aims: To analyze retrospectively the diagnostic accuracy of PET-CT in comparision with BMB in the initial staging of new FL in a single centre in daily practice.
Methods: One hundred and thirty-six patients with de novo FL have been diagnosed in our institution from June 2005 to October 2016. Of them, 64 who underwent both BMB and PET-CT before treatment were evaluated. The BMB was evaluated by hemato-pathologist and the interpretation of PET-CT images was interpreted by a nuclear radiologist. Positive BMB was defined as the presence of CD20 +,CD10+ y Bcl-2+ lymphoid infiltration. No molecular biology techniques were done in the bone marrow tissue. PET-CT bone marrow involvement was defined as an elevated FDG uptake in the bone marrow than those in liver or mediastinum.
Results: Thirty-five male and 29 female were included. The median age at diagnosis: 58 years (range 23-84). Thirty-four patients had grade 1-2 FL and 30 grade 3a FL. Bone marrow involvement was diagnosed in 33 of 64 patients (51.1%) by BMB. Out of the 17 patients with positive PET-CT, 4 had negative BMB. Out of 33 patients with positive BMB, 13 had a positive PET-CT (Table 1). The sensitivity and specificity of PET-CT was 39% and 87%, respectively. The positive predictive value and negative predictive value was 76.5% and 57%, respectively.

Table 1. Detection of BMO involvement: BMB and PET-CT results.

	BMB –	BMB +	TOTAL
PET -	27 (87%)	20 (61%)	47 (73%)
PET +	4 (13%)	13 (39%)	17 (27%)
TOTAL	31 (100%)	33 (100%)	64 (100%)

Summary/Conclusions: Our study shows a very low sensitivity of PET-CT in the daily practice. These results contrast with those reported in some recent studies in agressive lymphoma. However, the high positive predictive value raises the question about the uselfulness of BMB in these PET-CT positive cases. In our opinion, with the current data, BMB should be performed in indolent NHL patients.

SURVIVAL OUTCOMES AFTER FIRST-LINE THERAPY IN FOLLICULAR LYMPHOMA USING A UNITED STATES ELECTRONIC MEDICAL RECORD-BASED COHORT

A. Galaznik[1,*], J. Bell [1], L. Hamilton[2], A. Ogbonnaya[2], A. Raju[2], K. Hennenfent[2], M. Eaddy[2], Y. Shou[1]
[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Phar-

maceutical Company Limited, Cambridge, [2]Xcenda LLC, Palm Harbor, United States

Background: FL is a heterogeneous disease, and clinical presentation is highly variable. The Follicular Lymphoma International Prognostic Index (FLIPI-2) identifies prognostic factors at diagnosis but does not predict in whom and when to initiate first-line therapy (1LT).[1] Recommended therapies for 1LT vary by stage, symptomatology, and tumor burden but include monotherapy with rituximab (R) or in combination with other chemotherapies. Survival of FL patients in the R era has greatly improved, but few studies have evaluated survival outcomes in patients seen in routine clinical care.
Aims: This study aimed to evaluate survival outcomes in a US population of newly diagnosed FL patients seen in routine clinical care.
Methods: A retrospective study was conducted in which the presence of ≥1 inpatient record or ≥2 outpatient records with FL diagnosis codes were used to identified newly diagnosed FL patients from Humedica, a large US EMR database, between 01/01/08 and 07/31/15. The study index date was the first FL record. Patients who subsequently initiated 1LT for FL were followed from the date of treatment initiation until death, loss to follow-up, or end of study (09/30/15) for the evaluation of the survival outcomes. Median progression-free survival (PFS) (defined as initiation of second-line therapy, evidence of supportive care >30 days after the end of a line of therapy, or death), median overall survival (OS), and PFS and OS rates at 2 years following initiation of 1LT were evaluated using Kaplan-Meier analyses.
Results: 1,346 newly diagnosed FL patients who initiated 1LT met the patient selection criteria. 47.7% were male, and the mean age was 65.4 years (SD: 12.7). At baseline, 16.6% of patients had a Charlson Comorbidity Index of ≥2, and the most common comorbidities were diabetes (14.5%) and chronic pulmonary disease (11.2%). 1LT consisted of both monotherapy (38.6%) and combination therapy (61.4%). For monotherapy, R was the predominant agent used (85.8%); for combination therapy, bendamustine+R (43.8%) and R-CHOP (24.6%) were the most common. Kaplan-Meier analysis revealed that the 2-year OS and PFS rates (from initiation of 1LT) were 86.9% and 64.6%, respectively. Median OS was not reached, and median PFS was 48.1 months (95% confidence interval: 39.4, 58.4).
Summary/Conclusions: The 2-year OS and PFS rates in this newly diagnosed FL patient cohort who received 1LT (the majority of which was R-based) were consistent with expectations in a post-R era. Future analysis will explore the differences clinical characteristics and survival outcomes for patients who received R monotherapy and various R-combination therapies.

RITUXIMAB MAINTENANCE AFTER R.BENDAMUSTINE FOR PATIENTS WITH UNTREATED FOLLICULAR LYMPHOMA : A REAL LIFE STUDY IN SOUTHERN ITALY ON BEHALF OF RETE EMATOLOGICA PUGLIESE
G. Tarantini[1,*], S. Capalbo[2], F. Angrilli[3], N. Cascavilla[4], M. Ciminiello[5], C. Stelitano[6], G. Specchia[7], A. Guarini[8], P. Mazza[9], N. Di Renzo[10], V. Pavone[11]
[1]Dipartimento Oncoematologico ASL BT, U.O.C. di Ematologia con Trapianto ASL/BT Barletta - Italy, Barletta, [2]Ematologia , Foggia, [3]Ematologia, Pescara, [4]Ematologia, Sa Giovanni Rotondo, [5]Ematologia, Potenza, [6]Ematologia, Reggio Calabria, [7]Università di Bari, Cattedra di Ematologia, [8]IRRCS Oncologico Bari, Ematologia, Bari, [9]Ematologia, Taranto, [10]Ematologia, Lecce, [11]Ematologia, Tricase, Italy

Background: Results from phase 3 "StiL" and BRIGHT trials demonstrated the effectiveness of the combination Bendamustine-Rituximab {BR} compared to R-CHOP/R-CVP regimens as frontline treatment for advanced Follicular Lymphoma {FL}, emphasizing BR as a standard strategy in this subset of patients. However, only a few studies investigated the efficacy and safety of R maintenance after frontline BR, indicating a global beneficial effect of R administration in term of PFS but not OS, in keeping with a good toxicity profile even over two years of tratment
Aims: In this study, we evaluated the role of maintenance therapy with R after induction with BR in previously untreated FL, and compared its efficacy and safety profile with recent publicly available results of "StiL" trial.
Methods: FL patients [pts] were treated with a maximum of 6 cycles of B-R [Bendamustine 90 mg/m2 8days 1+2), Rituximab 375 mg/m2] every 28 days followed by 2 additional cycles of Rituximab monthly. Patients showing complete response [CR] or partial response [PR} were then allowed to receive R maintenance [375 mg/m2] administered every two months. To date 118 pts (65 women and 53 men) with FL have been recorded. Median age was 61 years (range 28-86); 15 (13%), 41 (35%), 62 (52%) pts had respectively stage II, III and IV; median number of nodal areas was 4, bone marrow involvement was found in 56 (47%) pts, and median FLIPI was 3.
Results: Among the 118 pts, 94 were evaluable for response and safety. The overall response rate [ORR] was 89.2% with 83 pts achieving a remission after BR therapy. The CR rate was 84.4%, 7 pts had partial response, 5 pts (6.1%) had stable disease, whereas 3 (3.5%) showed no response to BR and had a progressive fatal disease. All of the pts achieving remission received the full planned 2 years Rituximab maintenance treatment and, among them, 24 pts (28.9%) were administered with R over the first two years. Primary adverse events recorded were of grade 3 anf 4 in 25% of cases. Infectious (grade 3-4) and neutropenia (grade 3) were the most common adverse event, no additional unexpected toxicities were observed, whereas no occurrence of secondary malignancy was registered so far.
Summary/Conclusions: Our data, compared with recent reports about the role of Rituximab maintenance, support the efficacy of BR as backbone treatment of choice in previously untreated advanced FL. These results, moreover, are in line with those of other studies indicating that Rituximab standard maintenance and also over 2 years for FL appears safe and well tolerated, with no additional toxicities.

PB1879

ROLE OF F-18 FDG-PET/CT IN DETECTING LYMPHOMATOUS BONE MARROW INVOLVEMENT IN THE INITIAL STAGING OF PATIENTS WITH LYMPHOMA
B. Hernández Ruiz[1,*], C. Calle Primo[1], D. Buenasmañanas Cervantes[1], A. Mayoralas Tendero[1], R. Vanegas Uribe[1], M. Nebro Luque[1], A. Garcia Vicente[2]
[1]Haematology, [2]Nuclear Medicine Department, Hospital General Ciudad Real, Ciudad Real, Spain

Background: The role of F-18 FDG-PET/CT for the assessment of bone marrow involvement in the staging of newly diagnosed patients with lymphoma was reviewed in the Recommendations of Lugano Classification. They conclude that if a PET/CT is performed, a bone marrow biopsy is no longer indicated for a routine staging of Hodgkin lymphoma (HL) and most difusse large cell lymphoma (DLBCL). Data are insufficient in follicular lymphoma (FL) and bone marrow biopsy is always recommended.
Aims: We study the value of F-18 FDG-PET/CT for the detection of bone marrow involvement in the initial staging of patients with lymphoma.
Methods: Newly diagnosed patients with HL, DLBCL and FL who underwent F-18 FDG PET/CT and bone marrow biopsy for initial staging between January 2007 and June 2016 were included. We analyze sensitivity, specificity and concordance of PET/CT compared with bone marrow biopsy. In discordant cases, we review if there was any difference in the staging.
Results: 161 patients were included,69 DLBCL(38 male,31 female, median age 59 years),44 HL(24male,20female, me32y),48 FL (23male,25female, me55y). Four of the 44 patients with HL had bone marrow infiltration in bone marrow biopsy (BMB+) and PET/CT detected bone marrow involvement in all of these patients. PET/CT was positive in bone marrow (BMPET+) in 7 of the 40 patients without bone marrow infiltration in bone marrow biopsy (BMB-), these patients had bone marrow lesions on locations other than iliac crest. Six of the 7 patients were in advanced stage regardless of bone marrow involvement and a patient had sternal involvement by contiguity. Seven of the 69 patients with DLBCL had BMB+, 6 patients with DLBCL and 1 patient DLBCL and FL. PET/TC had detected bone marrow involvement in all of them. Sixty-two patients of 69 DLCL did not have bone marrow infiltration by biopsy(BMB-), but nine of them had BMPET+. Seven of the 9 patients were in stage IV because of extranodal involvement of other organs. One patient had primary bone involvement of jaw and another patient had vertebral involvement by contiguity. Fourteen patients of 48 patients with FL had BMB+. Of these 14 patients with bone marrow involvement by biopsy, 5 patients had BMPET- and PET/CT could not detect another extranodal involvement in three of these five patients. Of the 34 patients without bone marrow infiltration by biopsy BMO-, 8 patients had PET-TAC+, and 6/8 could be classified in stage IV regardless of bone marrow involvement (Table 1).

Table 1.

	n	BMB+		BMB-				
		PET+	PET-	PET+	PET-	Sensitivity	Specificity	Concordance
HL	44	4	0	7	33	100%	82,5%	84%
DLBCL	69	7	0	9	53	100%	85%	87%
FL	48	9	5	8	26	64,2%	86,6%	72,9%

Summary/Conclusions: Our series confirms that PET/CT is useful to detect bone marrow involvement in the initial staging of Hodgkin Lymphoma and DLBCL. We can avoid bone marrow biopsy in these hystological variants of lymphoma. In follicular lymphoma, PET/CT did not detect more than one third of patients with bone marrow infiltration by biopsy. These results support the histological assesment of bone marrow in the initial staging of follicular lymphoma.

PB1880

PREDICTIVE FACTORS FOR INFECTIOUS ADVERSE EVENTS IN PATIENTS WITH B-CELL NON-HODGKIN LYMPHOMA TREATED WITH BENDAMUSTINE-RITUXIMAB (R)±R MAINTENANCE. RESULTS OF A RETROSPECTIVE ANALYSIS

A. Di Rocco[1,*], F. De Angelis[1], L. Petrucci[1], F. Vozzella[1], D. De Benedittis[1], R. Foa[1], M. Martelli[1]
[1]Department of Cellular Biotechnologies and Hematology, University of Rome Sapienza, Rome, Italy

Background: The combination of bendamustine (B) and rituximab (R) is an effective and well tolerated treatment for B-cell malignancies. However, previous reports have shown a higher incidence of lymphopenia and secondary infectious complications in patients treated with BR than in patients treated with other chemoimmunotherapy regimens.
Aims: We performed a retrospective analysis at our institution in patients treated with BR with or without R maintenance, with the aim of determining the incidence of the infectious adverse events (AEs) and of identifying potential predictors factors.
Methods: We collected data from 65 patients with B-cell non-Hodgkin lymphoma (NHL) who received at least two cycles of BR±R maintenance between 2010 and 2016 at our institution. The AEs – including neutropenia (N), neutropenic fever (NF), lymphopenia, infections episodes and the occurrence of second tumors - were recorded according to the CTCAE v4.0 grade score. We compared the risk factors of patients who developed infections and those who did not. Univariate analysis with Fisher's exact test was used to evaluate the potential risk factors.
Results: The median age at the first treatment cycle was 66 years (range 36-89), 33 patients (50%) were ≥65 years, 27 (41%) were male, 53 (82%) had advanced disease and 37 (60%) had bone marrow involvement. Thirty (46%) patients had follicular lymphoma, 17 (26%) mantle cell lymphoma, 11 (17%) marginal lymphoma, 5 (7%) diffuse large B-cell lymphoma and 4% other indolent lymphomas. Thirty two patients (49%) received BR as first line treatment, 51% as second line and above. Bendamustine was administered either at the dosage of 70 or 90 mg/sqm iv on days 1, 2 and R was administered at a dose of 375 mg/sqm iv or sc, on day 1. Therapy was administered every 4 weeks up to 6 courses. Twenty nine patients (46%) received R maintenance every 8-12 weeks for two years. The mean number of cycles administered was 5 (range 2-6), 13 patients (20%) discontinued treatment due to toxicity: 8/13 for non-hematologic toxicity. Primary or secondary G-CSF prophylaxis was administered to 25 patients (38%), while the prophylaxis with trimetropin-sulfametoxazole against Pneumocystis jiroveci pneumonia was given to all patients. Twenty two patients (34%) had at least one infection. Bacterial pneumonia was identified in 6/22 patients, varicella zoster virus infection in 4/22, cytomegalovirus reactivation in 2/22 and other infections in 10 patients. At univariate analysis, the infectious AEs were associated only with lymphopenia during the second cycle (p=0.043) and with neutropenia during the second, third and fourth cycle (p=0.026; p=0.003, p=0.018, respectively). No correlation with age, line of treatment and G-CSF administration was documented. Other AEs were: grade 3/4 neutropenia (49%), neutropenic fever (3%), grade 3/4 lymphopenia (80%). We reported also a 5% incidence of second tumors after treatment (lung cancer in 2 patients and prostate cancer in 1).
Summary/Conclusions: In our analysis, BR±R maintenance confirms a toxicity profile similar to that reported in previous experiences. According to our results, an early lymphopenia and neutropenia (after two cycles) are predictive factors for infections AEs and for premature treatment discontinuation. Twenty% of patients discontinued treatment mostly because of the early withdrawal due to infectious complications. These data raise the question on the role of antibacterial, antiviral and primary G-CSF prophylaxis in all patients treated with BR.

PB1881

CAUSES OF DEATH OF FOLLICULAR LYMPHOMAS. MONOCENTRIC AND RETROSPECTIVE STUDY WITH A LONG PERIOD OF OBSERVATION

L. Rigacci[1,*], S. Kovalchuk[1], F. Lancia[2], G. Manneschi[3], B. Puccini[1], G. Benelli[1], L. Mannelli[1], A. Bosi[1]
[1]Haematology, AOU Careggi University of Florence, Florence, [2]Oncology, Ospedale Ferrara, Ferrara, [3]Istituto per la Prevenzione Oncologica, ISPO Firenze, Firenze, Italy

Background: Follicular lymphomas are usually defined as incurable diseases with a natural history characterized by continuous relapses.
Aims: This study was launched to evaluate after a long observation period the causes of death during follow-up.
Methods: All patients with histologically confirmed diagnosis of follicular lymphomas grade I-II or IIIa were selected from our data base starting from January 2000 untill December 2004 in such a way to have more than 10 years of observation for alive patients. We considered all patients with this diagnosis regardless to treatment and considering also patients followed with watch and wait. Patients were followed with ambulatory evaluation and for those lost to follow-up consulting the regional cancer registry.
Results: One hundred and fourthy-six patients were diagnosed and treated at our Institution. The median age at diagnosis was 61 years (range 30-87). Stage I-II in 47 patients, III-IV in 86. Bone marrow biopsy was positive in 87 patients, FLIPI 0-1 in 40, FLIPI 2 in 48, FLIPI 3 in 40 and FLIPI 4 in 18 patients. According to treatment 98 patients were treated with antracycline containing regimens, 34 with fludarabine containing regimens and 14 were observed or treated with radiotherapy. Rituximab was used in 98 patients, as sequential treatment in 74 or chemotherapy combined in 24; 48 patients did not use rituximab. The median observation period for alive patients was 13,4 years (range 11-15 years) and 8 years (range 0,09-15 years) for dead patients. Sixty-five patients dead during this long period of observation and the causes were: 35 due to lymphoma progression (54%), 16 second neoplasms (25%), 12 other disease (18%), 1 car accident and 1 unknown. The overall survival with a median period of observation of 127 months (range 2-196) was 71%. In univariate analysis the best overall survival was statistically associated with low FLIPI score, the use of Rituximab and the obtainment of complete remission. In multivariate analysis FLIPI 0-1 and the obtainment of complete remission manteined the significance. Exactly the same results were observed if we considered the cause specific mortality.
Summary/Conclusions: In conclusion this retrospective monocentric study confirms that after a long follow-up period about half patients died of lymphoma and the other half died for complications related to therapy or to lack of immunological control (second neoplasm or other diseases). Follicular lymphoma confirms to be a good prognosis lymphoproliferative disorders and in the long observation period of patients clinicians must have maintained a careful evaluation of concomitant pathologies.

PB1882

CLINICAL CHARACTARISTICS AND PROGNOSIS OF PATIENTS WITH INDOLENT NON-HODGKIN LYMPHOMA AND RISK OF TRANSFORMATION TO AGGRESSIVE LYMPHOMA: A SINGLE JORDANIAN CENTER EXPERIENCE

D. Zahran[1,*], M. Ayesh (Haj Yousef)[1], T. Kewan[1], S. Al Bashir[2]
[1]Internal Medicine, [2]Pathology, King Abdulla University Hospital (KAUH), Irbid, Jordan

Background: Indolent Non Hodgkin Lymphomas (INHL) are slow growing lymphomas that usually arise from B-cells. They are characterized by slow appearance and progression of symptoms compared to aggressive non Hodgkin lymphoma (NHL) namely Diffuse large B-cell Lymphoma (DLBL). Small percentage of INHL might transform to aggressive NHL.
Aims: We aim to describe the clinical characteristics, prognosis and risk of transformation to aggressive lymphoma in patients with INHL in North Jordan as a model for other Middle East countries in which such data is lacking.
Methods: All patients diagnosed with INHL between Jan 2003 to Jan 2017 were retrospectively reviewed. Clinical and laboratory data at time of diagnosis including gender, age, lactate dehydrogenase level (LDH), pathological subtypes, CT and PET/CT scans were studied. Extranodal involvement was confirmed either by histopathological studies or CT and PET/CT scan. Transformation to aggressive lymphoma was confirmed by histopathological studies. Patients were followed and overall survival rate was calculated. Mean survival times were calculated using Kaplan-Meier method.
Results: Among 265 patients diagnosed with NHL, only 88 patients (33.20%) confirmed to have INHL. 54 patients (61.4%) were males and 34 patients (38.6%) were females. Their ages at diagnosis ranged from (29-83) years with a mean (SD) of 59.26 (12.39). Among these patients, 45 patients (51.1%) had small lymphocytic lymphoma / chronic lymphocytic leukemia (CLL), 20 patients (22.7%) had follicular lymphoma (FL), 15 patients (17%) had marginal zone lymphoma (MZL), 6 patients (6.8%) had mantel cell lymphoma (MCL) and 2 patients (.78%) had unspecified INHL. Mean age of MZL (53.2 years) and FL (55.3 years) were significantly lower than mean age of MCL (58 years) and CLL (62.77 years). 22 patients (23.9%) had extra nodal Involvement. There was significant association between INHL subtypes and extra nodal sites involvement. (P-value=.001). 60% of patients with MZL, 50% of patients with MCL, 20% of patients with FL and 8.9% of patients with CLL had extranodal sites involvement. 11 patients (12.5%) from all INHL had transformed to Diffuse Large B-cell Lymphoma (DLBL). There was significant association between INHL subtypes and transformation to DLBL, (P-value=.02). 7 from 20 patients with FL (35%) and 4 from 45 patients with CLL (8.9%) had transformed to DLBL. Mean LDH level (886.1 U/L) in patients with transformation to DLBL was significantly higher than mean LDH level (490.7U/L) in other patients, (P-value=.0004). There was no significant association between mean age and mean albumin level with risk of transformation to DLBL. The overall survival rate was 56.8%. 10 years and 5 years survival rates were 47% and 60% respectively. Mean survival time in patients with MCL (31.8 months) was significantly lower than mean survival time in patients with follicular (85.48 months) , MZL (90.6 months) and CLL(103.6 months) patients , (p-value=.oooo4). There was no significant difference in survival rate between patients who transformed and patients who didn't transform to DLBL.
Summary/Conclusions: Prevalence of INHL among patients with NHL in North Jordan is 33.2%. The most common INHL subtypes in our patients were

CLL (51.1%) and FL (20.7%). These findings are significantly different from Saudi Arabia and Western Countries in which FL is the most common subtype. FL and CLL are associated with higher risk of transformation to DLBL. High LDH level is considered a risk factor for transformation to DLBL in our patients. MCL is associated with significantly lower mean survival time than other INHL subtypes.

PB1883

OCULAR ADNEXAL LOW GRADE LYMPHOMA TREATMENT OUTCOMES AND LONG TERM FOLLOW UP: A SINGLE CENTRE EXPERIENCE

N. Elmusharaf[1,*], C. Bloodworth[1], B. Skippen[2], M. Hourihan[3], T. Parmar[2], D. Morris[2], C. Lane[2], C. Rowntree[1]
[1]Haematology, [2]Ophthalmology, [3]Radiology, University Hospital of Wales, Cardiff, United Kingdom

Background: Ocular adnexal lymphoma (OAL) accounts for 1-2% of Non-Hodgkin Lymphomas (NHL) and 8% of all extra-nodal sites. The majority of cases, >95%, are of B cell origin and 80% are low grade lymphomas. Secondary ocular involvement occurs in approximately 2.4-5.3% of patients with advanced systemic NHL. Marginal zone lymphoma or mucosa-associated lymphoid tissue (MALT) lymphoma is reported in approximately 50% of patients. Current treatment options for low grade OAL include radiotherapy and chemotherapy. Chlamydia Psittaci DNA has been reported in up to 80% of tumor biopsies from patients with OAL suggesting a possible value of anti-Chlamydia Psittaci antibiotic therapy.
Aims: To report a single centre's experience in the outcomes of patients diagnosed with OAL over a 13 year period.
Methods: A Retrospective cohort of patients with low grade OAL treated in a single Centre between 2003 and 2016 was analyzed. Chemotherapy was the first choice of therapy until 2008, afterwards radiotherapy became the first line treatment for OAL.
Results: A total of 20 patients with OAL were identified. 60% (12/20) of patients were females with a median age of 61.5 years (range 45-85 years). 80%(16/20) had unilateral disease at presentation. MALT lymphomas comprised 75%(15/20), Follicular NHL 15% and CLL/SLL 10%. Only 10% (2/20) had a prior diagnosis of NHL. At presentation 20% (4/20) had evidence of systemic involvement: 19% (3/16) had bone marrow involvement and 1 patient had small volume lymphadenopathy on CT scan. 45% (9/20) were treated with first line chemotherapy, single agent Chlorambucil in 78% (7/9) and 2 patients received Fludarabine based chemotherapy, 30% (6/20) received first line radiotherapy, 24Gy in 12 fractions in 67% (4/6), and 25% (6/20) were managed under observation. In the chemotherapy group 55% (5/9) experienced 1 relapse (3/5 local recurrence and 2/5 extra-ocular relapse), 3 patients experienced ≥2 relapses, 2 patients had disease transformation to high grade and 1 patient subsequently died as a consequence of their disease. 33% (2/6) patients treated with radiotherapy experienced disease recurrence, mainly extra-ocular and 50% (3/6) suffered complications following radiotherapy in the form of dry eyes and cataract. Median follow up was 9.5 years (range 1-14 years). Overall survival was 95% (19/20) with an event free survival of 65% (13/20) (Table 1).

Table 1. Summary of the management modalities of ocular adnezal low grade non-Hodgkin lymphoma.

	Chemotherapy	Radiotherapy	Observation	Total
Number of patients	9	6	5	20
Follow up median, range years	11 (9-14)	2.5 (2-5)	2 (1-9)	9.5 (1-14)
Relapsed	5 (55%)	2 (33%)	0	7 (35%)
Event Free Survival	4 (45%)	4 (67%)	5 (100%)	13 (65%)
Complications	2 (22%)	3 (50 %)	0	5 (25%)
Overall Survival	8 (89%)	6 (100%)	5 (100%)	19 (95%)

Summary/Conclusions: The majority of patients in our cohort had favorable outcomes. Currently there is no national guideline for the management of OAL in the UK. Several treatment options exist including chemotherapy, radiotherapy, immunotherapy, observation or more recently the use of eradication treatment for Chlamydia Psittaci. Factors to consider when choosing a treatment include a patient's co-morbidities, risk of visual impairment, need for systemic therapy, histological diagnosis and anticipated side effects. As treatments are so effective the long term consequences and possible late effects need to be acknowledged and avoided if at all possible. Observation is an acceptable approach in asymptomatic patients when there is no immediate risk of visual impairment. Radiotherapy is an effective first line treatment in symptomatic and localized OAL, the exact dose of radiotherapy to achieve disease control with minimal long term side effects is yet to be determined. Reviews with larger number of patients are needed to inform a practical approach to the management of OAL.

PB1884

AGE AS A POTENTIAL NOVEL PROGNOSTIC INDICATOR IN PRIMARY CUTANEOUS B-CELL LYMPHOMA

P. Desai[1,2,*], M. Van den Bergh[3,4], H. Zhang[5], X. Zhang[5], B. Schaible[6], Z. Ma[6], L. Sokol[7]
[1]Internal Medicine, University of South Florida, [2]Internal Medicine, [3]Hematology and Oncology, H. Lee Moffitt Cancer Center and Research Institute, [4]Hematology and Oncology, University of South Florida, [5]Oncologic Sciences, Pathology, and Cell Biology, [6]Biostatistics and Bioinformatics, [7]Malignant Hematology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, United States

Background: Primary Cutaneous B-Cell Lymphoma (PCBCL) comprises a rare group of cutaneous Non-Hodgkin's lymphomas (NHLs) with an estimated annual incidence of 2.5 per 1,000,000 persons. They usually present with papules or nodules on the head, trunk, and/or extremities. The International Society for Cutaneous Lymphoma (ISCL) and the European Organization for Research and Treatment of Cancer (EORTC) developed a new way to classify PCBCL into three different subtypes. Indolent subtypes include Primary Cutaneous Marginal Zone Lymphoma (PCMZL) and Primary Cutaneous Follicular Center Lymphoma (PCFCL). Primary Cutaneous Diffuse Large B-Cell Lymphoma (PCDLBCL) is an aggressive subtype with a fatality rate of 50%. The Cutaneous Lymphoma International Prognostic Index (CLIPI) can risk stratify indolent subtypes, but criteria do not include age. Here we present our single institutional analysis of clinicopathological features and outcomes of patients with PCBCL.
Aims: To analyze clinical and laboratory characteristics such as age, lesion characteristics, hematological parameters, and treatment modalities in order to determine their impact on progression free survival (PFS) in PCBCL.
Methods: This is a retrospective study of patients evaluated at Moffitt Cancer Center between January 1990 and December 2016. Patients were identified using our PCBCL database and diagnosis was verified by independent hematopathologists and dermatopathologists. Staging was determined according to ISCL/EORTC recommendations. Demographics, lymphoma subtype, stage, disease course, and CLIPI scores were collected. Kruskal Wallis ANOVA and Fisher's Exact tests were used to compare differences among the four subtypes for continuous and categorical variables, respectively. Kaplan Meier curves were produced to estimate PFS for different strata, and differences among the strata were tested using the log-rank test.
Results: We identified 37 patients who met diagnostic criteria for PCBCL (35% PCFCL, 40.5% PCMZL, 13.5% PCDLBCL, and 11% indolent, unspecified). Male:female ratio was 2.4:1. 51% of patients were ≥60 years old (yo) and 49% were <60 yo. 54% had stage T1 disease, 27% T2, and 19% T3. Median PFS for patients <60 was 1.1 years, but was not reached for those ≥60. Mean follow-up time was 2.6 years for all patients. Log rank test showed a statistically significant difference in PFS between the two age groups (p=0.01). This was consistent when comparing PFS by age in both high (PCDLBCL) and low grade (indolent) subtypes. PFS according to stage in indolent subtypes showed a marginally statistically significant difference (p<0.06). Stratification of patients according to CLIPI did not show a significant difference in PFS among indolent subtypes.
Summary/Conclusions: We found that age is a highly statistically significant prognostic parameter in PCBCL, as patients ≥60 years had a longer PFS compared to younger patients, even after adjusting for stage and CLIPI. This is an interesting finding as most NHL studies demonstrated a negative impact of advanced age on PFS. Our results suggested that age is a possible novel prognostic indicator in patients with PCBCL, however validation on a larger sample set is needed.

PB1885

EPIDEMIOLOGY, CHARACTERIZATION AND THERAPEUTIC MANAGEMENT OF MARGINAL ZONE LYMPHOMA: A SINGLE-CENTER EXPERIENCE

C. De Miguel[1,*], B. Navarro[1], J. Martín[2], P. Martín[2], R. Forés[1], C. Bellas[2], J.R. Cabrera[1]
[1]Hematology, [2]Pathology, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain

Background: Marginal zone lymphomas are a group of relatively uncommon lymphomas whose cells are derived from B lymphocytes of the "marginal zone" of the secondary lymphoid follicles.
Aims: The objective of this study is to review our series evaluating the epidemiology, clinical presentation, morphological, immunohistochemical and molecular characterization and therapeutic management in a tertiary hospital.
Methods: We evaluated a total of 56 patients diagnosed between May 2008 and February 2017. We collected the epidemiological and clinical data, including location, clinical stage, FLIPI and associated risk, antigenic stimulus, symptomatology at diagnosis (ECOG, constitutional syndrome, B symptoms) and response to treatment. We reviewed the levels of LDH, beta2microglobulin, ESR, peripheral blood (PB) immunophenotype and studied the morphological, immunohistochemical and molecular characteristics (MALT1 translocation and

immunoglobulin heavy chain rearrangement (CDR2 / CDR3 of IgH)) in PB, bone marrow and affected organs. All diagnoses were classified according to WHO (2016 revision). In addition, we performed an autoimmunity test in most patients.
Results: Among the 56 patients, 26 were men (46.4%) and 30 women. The median age at diagnosis was 64 years (37-92). The most frequent subtype was the splenic marginal zone lymphoma (17 patients, 30.4%), followed by MALT: 10 pulmonary (17.9%), 10 gastric (17.9%), 5 cutaneous (8.9%), 5 ORL (8.9%), 2 (3.6%), 1 hepatic, 1 thyroid and 1 lacrimal gland (1.8%) and nodal marginal zone lymphoma (3 patients, 5.4%). Five of them presented with multifocal disease (8.9%). Fifty percent (28) had a clinical stage III / IV and 32 patients (57.1%) had a low risk at diagnosis (FLIPI 0-1). We found an antigenic stimulus in 11 patients (Helicobacter pylori, Sjögren's syndrome, Hashimoto's thyroiditis). The molecular study of MALT1 was performed in 25 patients and 3 presented the translocation (12%). Six of seventeen cases (35.3%) showed IgH rearrangements. Antinuclear antibodies were positive in 15 of 32 patients (46.9%). A total of 46 patients (82.1%) required a treatment, of whom 35 achieved a complete remission (CR) (76.1%) and 10 partial remission (PR) (21.7%) after the first line of treatment. Among these, 17 received immunochemotherapy (37%), 10 immunotherapy (21.7%), 8 surgery (17.4%), 7 antibiotics (15.2%) and 4 radiotherapy (8.7%). We observed 7 relapses (16.7%) and 3 progressions (7.1%), achieving a CR in 7 (70%) and PR in 3 (30%) after rescue treatment. There was just one case of high grade transformation (1.8%), who was the only patient decesed in the series (1.8%), with a median follow-up of 70 months.
Summary/Conclusions: Marginal zone lymphoma is an indolent lymphoma, with a good prognosis and very good response to current therapy. It is sometimes associated with autoimmune phenomena and infectious agents. It is essential a correct staging and characterization to optimize its therapeutic management and outcome.

PB1886

HAIRY CELL LEUKEMIA AND B-RAF MUTATIONS
A. Olgun[1], Y. Baskın[2], S. Solmaz Medeni[3], I. Alacacioglu[1], M. Akbapour[2], T. Uysal[2], O. Birge[4], S. Ozkal[4], H. Ellidokuz[2], M.A. Ozcan[1,*]
[1]Dokuz Eylul University Hematology Dept., [2]Dokuz Eylul University Oncology Institute, [3]Bozyaka Training and Research Hospital, [4]Dokuz Eylul University Pathology Dept., Izmir, Turkey

Background: Hairy cell leukemia(HCL) is a B cell lymphoproliferative disorder, presenting with splenomegaly, hepatomegaly and bone marrow infiltration. HCL accounts for%4,5 of non-Hodgkin lymphomas, more commonly seen in man. Diagnosis is based on the examination of peripheral blood smear, flow cytometry and the bone marrow aspiration-biopsy. Recently, B-RAF^{V600E} mutation was demonstrated in%100 of Tiacci HCL case series.
Aims: Aim of our study is to investigate the frequency of B-RAF^{V600E}mutation and other rare mutations of B-RAF (B-RAF^{G464E}, B-RAF^{G466E}, B-RAF^{G469V}) and their relation with clinical data and treatment responses.
Methods: Charts of 13 patients diagnosed with HCL were analyzed retrospectively. Patients' clinical paremeters were evaluated. HCL variant type patients were excluded. Paraffin blocks of spleen or bone marrow tissues are obtained from the pathology archives. One thin section (10 micron) of bone marrow or three sections of spleen are cut and DNA extracted by spin column technique using DNA extraction kit. (QIAamp DNA FFPE Tissue Kit, Qiagen) After spectrophotometric measurement of DNA; common and uncommon mutations of B-RAF were investigated. (Qiagen PyroMark Q24 system, Therascreen BRAF Pyrokit 24, V1 (1/2) kit) Mutation and clinical data analysis were conducted using the SPSS 15.0 software. The study was approved by the local ethics board of Dokuz Eylul University.
Results: Male/female ratio was 9/4. Median age at diagnosis was 48(37-59). Median follow-up time was 59 (3-96) months. At the time of diagnosis, 46,2% (n=6) of patients were asymptomatic. All of the patients had splenomegaly (n=13), five patients had hepatomegaly and two had intraabdominal lymhadenopathy. Approximately half of the patients (%46,2) diagnosed with splenectomy. Only one patient was pancytopenic at diagnosis. Four patients were anemic (Hemoglobin<10 gr/dL), six were thrombocytopenic (Platelets<150000/µl). Leucopenia was seen in 84,6% (n=11) of the patients. Monocytopenia commonly seen in HCL was detected in 61,5%. One of the patients was diagnosed and treated due to Mantle cell lymphoma (MCL) a year ago and found in remission for both MCL and HCL; one was diagnosed Kaposi carcoma just before the diagnosis of HCL and lost in follow-up. Twelve patients were hospitalized and treated with one cycle of cladribin (0,1 mg/kg/day IV for 7 days). One of these patients received SC IFNα at a dose of 4,5 mIU/day prior to cladribin therapy. Treatment responses could be evaluated in eleven patients and all of the patients gained CR. Survival analysis couldn't be done because non of the patients had progressed or died. B-RAF^{V600E} mutation was positive in 10(%76,9) patients. Three (%23,1) of the patients had B-RAF 464-469 codon mutations (One B-RAF^{G464E}, one B-RAF^{G466E}, one B-RAF^{G469E}) Two patients were positive for both mutations. No relation could be determined between clinical findings and mutation state.
Summary/Conclusions: B-Raf mutations are variable and common mutations in HCL patients. B-RAF^{V600E} mutation testing can be used as a supportive test for the diagnosis of HCL due to high incidence of mutation. Also it can be used as an indicator for patient selection that are appropriate for target therapies.

PB1887

BENDAMUSTINE-RITUXIMAB IN PATIENTS WITH RELAPSED FOLLICULAR LYMPHOMA PREVIOUSLY EXPOSED TO RITUXIMAB. EXPERIENCE IN SEVEN HOSPITALS OF THE SPANISH GELTAMO GROUP
J.A. Soler Campos[1,*], M. Martinez[1], B. Sanchez-Gonzalez[2], M.B. Navarro[3], S. Novelli[4], S. Mercadal[5], E. Perez Ceballos[6], N. Kelleher[7], A. Asensio[8]
[1]Hematology, Hospital Universitari Parc Tauli Sabadell, Sabadell, [2]Hematology, Hospital del Mar, Barcelona, [3]Hematology, Hospital Univeristario Puerta de Hierro, Madrid, [4]Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, [5]Hematology, ICO H. Duran i Reynals., Bellvitge, [6]Hematology, Hospital Universitario Morales Messeguer, Murcia, [7]Hematology, Hospital Josep Trueta, Girona, [8]Hematology, Hospital Sant Camil, Sant Pere de Ribes, Spain

Background: Follicular lymphoma (FL) is characterized by a course of relapses and increasingly shorter responses to the consecutive treatments. In first relapse after immunochemotherapy, in patients who are not considered refractory to rituximab, there is no standard treatment. In Spain, bendamustine in association with rituximab (BR) has not been approved for this indication. Nevertheless this combination has shown high efficacy and excellent tolerance in patients previously treated with and without rituximab.
Aims: To evaluate the efficacy and safety of the bendamustine-rituximab association in a group of patients with follicular lymphoma previously exposed to rituximab.
Methods: Retrospective analysis of patients with relapsed FL treated with BR in 7 spanish hospitals on behalf of the Spanish Lymphoma Group (GELTAMO). The study was approved by the reference Ethic Committee and by all of the participating centres. All patients acceded to the treatment through the compassionate use program.
Results: 41 patients were valid for analysis. Characteristics: 70% males with a mean age of 62 years (30-87). ECOG≤ 2 in 95% of cases, 73.2% in stages III-IV and FLIPI ≥3 in 48%. Bulky mass in 13% of patients, LDH and β2-microglobulin increased by 12% and 41.2% respectively and bone marrow involvement in 60%. 68% had received only one previous treatment, with an average of 1.7 (1-5) and the most frequent was CHOP-R in 66% followed by CVP-R in 11%. All patients had previously received rituximab and only 3 patients (7.3%) could be considered refractory. All patients received BR (B-90 mg / m2 D1-2, R-375mg / m2 D1). Median cycles 5.1 (1-6). Support with G-CSF was used in 27.5% of cycles. Maintenance with rituximab after obtaining a complete (CR) or partial remission (PR) was administered in 42% of patients. Response: The overall response rate was 95.1% (65.8% CR-iCR / 29.3% PR). With a median follow-up of 25 months (6-92) the median response duration was 41.9 months (32.8-51.1) and the median progression-free survival (PFS) was 57 months (27.4-86.5) with no impact neither by the number of previous treatments (1 *vs* ≥2) (P=0.69) nor by the age (<70 *vs* ≥70) (P=0.9). Patients who received maintenance with rituximab after BR had a significantly longer median PFS than without (NR *vs* 32) (p=0.004). Toxicity: No treatment-related death was recorded. 42% and 36.6% of the patients presented G3-4 neutropenia and thrombocytopenia respectively, although only 2 patients were admitted due to febrile neutropenia. 43% received cotrimoxazole prophylaxis and 3 opportunistic infections were recorded (1 *P. jirovecii* pneumonia in a patient without prophylaxis).
Summary/Conclusions: BR has a high efficacy and a good safety profile in this series of patients with relapsed FL previously exposed to rituximab. The number of previous treatments (1 *vs* ≥2) and the age had no impact in the results.

PB1888

USE OF RADIATION THERAPY FOR THE TREATMENT OF GASTRIC MALT LYMPHOMA
E. Gonzalez[1,*], L. Díaz[1], M. J. Macias[1], V. Diaz[1], I. Villanego[1], S. Garduño[1], C. Salas[1], L. Gutierrez[1], J. Jaen[1]
[1]Radiation Oncology, H.U. Puerta del Mar, Cadiz, Spain

Background: Gastric mucosa-associated lymphoid tissue (MALT) lymphoma is a rare disease however, the incidence is increasing and closely associated with helicobacter pylori (HP) infection. One choice of treatment of gastric MALT lymphoma refractory to HP sterilization is radiotherapy.
Aims: Our aim was to analyze the response to treatment with definitive radiotherapy in our department.
Methods: Between January 2014 and January 2017, 8 patients with gastric MALT lymphoma were treated with eradication therapy of HP, followed by definitive radiotherapy. The average total dose was of 38 Gy to the stomach in a once-daily scheme. Follow-up included computed tomography scan and

endoscopy with biopsies at regular intervals. The median follow-up was 14 months.
Results: In all patients we got complete responses (CR) with no tumor detectable by endoscopy or biopsy after initial treatment, but after 2 years one of them relapsed and required immunochemotherapy. The most common acute toxicities were fatigue and nausea, in our patients. In any case late toxicities were observed. The overall survival was 100% after 2 years.
Summary/Conclusions: In selected patients who are not responsive to HP sterilization, definitive radiotherapy can be an efficient therapy with tolerable complications, preservation of stomach and sustained response over time.

Infectious diseases, supportive care

PB1889

USE OF LIPEGFILGRASTIM IN CLINICAL PRACTICE FOR THE PROPHYLAXIS OF CHEMOTHERAPY-INDUCED NEUTROPENIA IN LYMPHOMA PATIENTS: INTERIM RESULTS OF A PAN-EUROPEAN NON-INTERVENTIONAL STUDY

N. Cascavilla[1,*], T. Wrobel[2], E. Hatzimichael[3], E. Wojciechowska-Lampka[4], P. Mazza[5], K. Kargar[6], M. Lenzhofer[7]
[1]Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy, [2]Wroclaw Medical University, Wroclaw, Poland, [3]University Hospital of Ioannina, Ioannina, Greece, [4]MSC Cancer Center and Institute, Warsaw, Poland, [5]SS Annnziata Hospital, Taranto, Italy, [6]Hospital Center of Wallonie Picarde, Tournai, Belgium, [7]Schwarzach Hospital, Schwarzach im Pongau, Austria

Background: Lipegfilgrastim (Lonquex®) is a long-acting fixed-dose glycopegylated granulocyte colony-stimulating factor administered once per chemotherapy cycle. It has been available in Europe since 2013. It was proven to be non-inferior with regard to duration of severe neutropenia compared with pegfilgrastim in breast cancer patients. However, data in patients with hematological malignancies are limited.
Aims: We aimed to evaluate the effectiveness of lipegfilgrastim in the cycle following the first lipegfilgrastim-supported treatment cycle in lymphoma patients.
Methods: This is a prospective observational cohort study. Patients with different tumor types treated with cytotoxic chemotherapy (CT) who received lipegfilgrastim in primary prophylaxis (PP) or secondary prophylaxis (SP) are being included in this study. CT dose modifications and neutropenia-related events are recorded and analyzed. Evaluation of effectiveness in the cycle following the first lipegfilgrastim-supported CT cycle in a lymphoma subpopulation is presented here.
Results: At the time of the interim analysis (December 2016), 249 patients diagnosed with lymphoma have been included. Mean age±standard deviation of lymphoma patients was 61.6±15.6 years and 56.6% were male. For the majority of patients (81.1%), intended use of lipegfilgrastim was in PP. Exposure to lipegfilgrastim has been documented for 228 patients with an average of 4.76 cycles per patient. Data on CT dose modifications and neutropenic events following the first lipegfilgrastim-supported cycle were available for 144 and 167 patients, respectively. CT dose was never omitted. CT dose delays were observed in 8.0% (PP) and 18.8% (SP) of patients and CT dose reductions in 4.5% (PP) and 12.5% (SP) of patients. In the first lipegfilgrastim-supported cycle, febrile neutropenia was recorded in 4.5% (PP) and 3.0% (SP) of patients; severe neutropenia was recorded in 7.5% (PP) and 9.1% (SP) of patients. Throughout the treatment, 22 (9.6%) patients exposed to lipegfilgrastim reported at least 1 adverse drug reaction (ADR). The most common ADRs were myalgia and musculoskeletal pain. Serious ADRs were reported by 11 (4.8%) patients.
Summary/Conclusions: Lipegfilgrastim is effective and well tolerated in the real-world setting in lymphoma patients, administered either in PP or SP. The results suggest that lipegfilgrastim administered in PP might give better outcomes in terms of dose delays and dose reductions than when administered in SP.

PB1890

TUBERCULOSIS IN ACUTE LEUKEMIA- AN ANALYSIS OF CLINICAL CHARACTERISTICS AND IMPACT ON MANAGEMENT IN 25 PATIENTS

C. Singh[1,*], A. Jain[2], G. Prakash[2], P. Malhotra[2], S. Varma[1]
[1]Internal Medicine, [2]Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India, Chandigarh, India

Background: Patients with acute leukemia represent an immuno-compromised population, with innate, humoral and cellular immune paresis. These patients are thus at high risk of development of new infections and reactivation of chronic infections. Despite the high prevalence of tuberculosis in the general population in endemic countries, it is rarely suspected and diagnosed in patients with acute leukemia.
Aims: To study the clinical manifestations of tuberculosis in patients with acute leukemia, as well as the impact of infection in the management of leukemia
Methods: A hospital database search was done to identify cases of acute leukemia and tuberculosis between a study duration of January 2013 to January 2017. All the medical records of the identified cases were retrieved from the central records department. A systemic analysis of characteristics pertaining to acute leukemia, treatment regimen, chemotherapy response, site of tubercular infection, mode of diagnosis and treatment response to anti-tuberculous therapy was conducted.
Results: A total of 25 patients with acute leukemia were identified who were also diagnosed with tuberculosis. 10 patients had Acute Myeloid Leukemia, 7 had Acute Promyelocytic Leukemia, 5 had Acute Lymphoblastic Leukemia, 2 had Mixed Phenotypic Leukemia while 1 had Myeloid Sarcoma. The mean interval between diagnosis of tuberculosis and acute leukemia was 37.2 weeks, with 2 patients being diagnosed after completion of therapy of acute leukemia

and one patient was diagnosed post mortem. The most common organ involved was the lung, which was seen in 80% of patients and 20% of patients had disseminated tuberculosis. The development of tubercular infection led to alteration of therapy for the acute leukemia in 24% of cases, while it was postponed in 44% of cases. In particular, hypomethylating agents were used successfully in two patients with AML as bridge therapy to high dose chemotherapy. 76% of patients were cured of tuberculosis with therapy, while 1 patient expired due to tuberculosis and 3 patients could not receive adequate therapy for tuberculosis. 3 patients went on to undergo HSCT post treatment for tuberculosis, and none had a flare of the disease post transplant.
Summary/Conclusions: The presence of tuberculosis infection in patients of acute leukemia has an impact on the overall management of the patient, and strategies such as utilization of hypomethylating agents as bridge therapy may help in successful management of the leukemia. A high index of suspicion is required to suspect and diagnose the presence of tuberculosis as the manifestations are more commonly attributed to fungal infections or to the leukemia per say. These patients usually have a favorable response to anti-tuberculous therapy and the presence of tuberculosis infection does not forego treatment options such as HSCT or high dose chemotherapy for these patients.

PB1891

INCIDENCE OF BACTEREMIA BY MULTI-RESISTANT BACTERIA IN HEMATOLOGY PATIENTS. A DESCRIPTIVE EPIDEMIOLOGIC STUDY FROM A THIRD LEVEL HOSPITAL

A. Nieto Vazquez[1,*]
[1]Hematology, SERGAS. Hospital Alvaro Cunqueiro, Vigo, Spain

Background: In recent years the incidence of multi-resistant bacteria (MRB) infections have notably increase. These infections are especially serious in hematological patients because of the immunosupression derived from their illness and their treatments. This increase is related to a high mortality rate and high health costs due to the severity of the infections and the difficulty in setting adequate therapy due to the lack of new antibiotics against these pathogens.
Aims: Define the MRB infections incidence and ways of presentation. As a secondary goal we try to determine if the isolation of these MRB has affected our empiric antibiotic therapy decision.
Methods: We retrospectively collected all positive blood stream cultures from hematologic patients from January 2012 to December 2016. We studied the characteristics, clinical features and pathogen isolates of our patients when the blood cultures were obtained.
Results: 1005 positive blood stream cultures were collected in 382 patients. The main characteristics of the patients are shown on Table 1.

Table 1.

SEX	MEN 55% WOMEN 45%
MEAN AGE	57.5 (10 month – 96 years old)
DIAGNOSTICS	AML / MDS 20% ALL 5% CLPS 7% CMPS 4% MM 19% NHL 35% HL 5% OTHERS (ITP, NPH, APLASIA AIHA...) 5%
HSCT (36% OF ALL PATIENTS)	ALOHSCT 60% AUTOHSCT 60%
NEUTROPHILS	< 500: 35% 500-1000: 8% >1000: 57%
INFECTION SOURCE	CVC: 48% RESPIRATORY: 18% ABDOMINAL: 8% SKIN/ SOFT TISSUE: 7% URINARY: 5% MULTIPLE LOCATION: 5%

The infection source was: central venous catheter (CVC) in 48% of patients (including tunneled, non-tunneled and PICC lines), respiratory 10%, abdominal 8%, urinary 5%, skin/soft tissue 7% and multiple location 5%. Regarding CVC isolation's, 11% were interpreted as contamination and 6% as colonization. Gram positive (G+) bacteria were more frequently isolated than Gram negative (G-) (72% *vs* 24%). Most common G+ bacteria was coagulase negative Staphylococcus, regarding G- E. Coli, Klebsiella sp and Pseudomonas aeruginosa. MRB were detected in 6.1% of blood cultures being the most frequent G- (85%). The main resistance mechanism was extended-spectrum beta-lactamases (ESBL) and carbapenemases (CP) production (Table 2). BMR infections increased significantly in last year, mainly associated to CP, 0.5% in 2012 up to 7.1% in 2016 (Figure 1). 29.5% of MRB infections developed in patients identified as chronic carriers of multiresistant organisms and 100% of them had extensive exposure to wide spectrum antimicrobials previously. 14% of infections began with a serious illness (persistent hyperthermia, hemodynamic disbalance and worsening), 5% needed intensive care assistance and 15% died because of the infection. In MRB infections, 44% were severe, 6% needed ICU and 25% died. The most common empirical antibiotic therapy was carbapenems - 12% in monotherapy, 17% with glucopeptids - followed by third generation cephalosporins in 7%. Related to febrile episodes in MRB known carriers: empiric treatment includes effective antibiotic against this MRB (including colistin and carbapenems in extended infusion) was started in 15% of patients, all with serious illness at diagnosis.

Table 2.

GRAM NEGATIVE MULTI-RESISTANTS BACTERIA	n
ESBL Escherichia coli	17
CP Klebsiella pneumoniae	11
ESBL Enterobacter cloacae	10
CP Pseudomona aeruginosa	8
ESBL Serratia marcescens	4
ESBL Proteus mirabilis	1
ESBL Citrobacter	1

Figure 1.

Summary/Conclusions: - Current antimicrobial resistance, especially concerning G- in our study, is particularly worrisome due to development of resistance to all available antimicrobial agents. The incidence of multi-resistant G+ is not very high. - Clinical presentation in MBR infections is more serious in our experience, and the mortality doubles in relation to the difficulty to establish appropriate treatment. - Severity sings at infection diagnosis in MRB carriers had led us to a change of empirical antibiotic therapy. - As reported in previous literature, prevention of transmission, a quick establishment of diagnosis and an effective treatment, along with a correct and limited use of antibiotic therapy could decrease the development of MRB.

PB1892

INFECTIONS PRESENTING IN THE BONE MARROW IN HIV POSITIVE PATIENTS AND THEIR MORPHOLOGICAL ASSOCIATIONS – SIX YEAR DATA FROM AN INDIAN TERTIARY CARE HOSPITAL

R. Gupta[1,*], S.L. Jain[1], P. Sobti[2]
[1]Pathology, Maulana Azad Medical College, [2]Pathology, Apollo hospital, Delhi, India

Background: Centre of Disease Control enlists more than 20 infections considered as Acquired Immunodeficiency Syndrome(AIDS) defining. Progression of the disease and falling CD4 counts are the most important risk factors in acquiring these infections. Most of the cases present with non specific symtoms including fever, respiratory and gastrointestinal manifestations . A bone marrow examination is helpful in estabilishing the diagnosis in many of these cases.
Aims: The aim of this study was to evaluate the incidence of marrow infections in HIV positive patients and to study their morphological spectrum.
Methods: This is a six year retrospective study carried out in a tertiary care hospital in North India. All bone marrow aspirates and biopsies from HIV positive patients were retrieved and evaluated for the presence of infectious etiology. Cytochemical stains like Acid Fast Bacillus, Periodic Acid Schiff , Gomori Methenamine Silver and Mucicarmine were performed wherever needed. The associated morphological features which may assist diagnosis were noted.
Results: Bone marrow samples (either aspirates or biopsies or both) were available in 185 HIV patients. Out of these, fifty three cases (33.5%) were associated with infections. The most common infection in these patients was Mycobacterium Tuberculosis (22.7%). In addition, five cases of Histoplasmosis (2.7%), two cases of Cryptococcosis, two cases of Leishmania donovanii, and one case of Plasmodium falciparum, Parvovirus and Microfilaria each were noticed. The morphological spectrum associated with infections in these cases included lymphoplasmacytic infiltrate(68%) , granulomas(66%), macrophage infiltration, hemophagocytosis, gelationous marrow transformation and marrow hypoplasia. Two cases of M tuberculosis were associated with maturation arrest in the bone marrow. One case of Tuberculosis was associated with Non Hodgkin's Lymphoma. Myelodysplasia was seen in association with Leishmania infection.

Summary/Conclusions: A wide spectrum of infections may be observed in HIV positive patients in the bone marrow. Bone marrow aspirate and biopsy are essential, rapid and cost effective techniques to arrive at the right diagnosis in such cases . Features like hypoplasia, myelodysplasia and maturation arrest may be attributable to infections.

PB1893

UTILITY OF BONE MARROW BIOPSY IN FEVER OF UNKNOWN ORIGEN: A CRITICAL ANALYSIS OF A RETROSPECTIVE SERIE

H.N. Fernandez - Leyva[1,*], J. Bosworth[1], M. Offer[1], N. Ansar[1]
[1]Haematology, Frimley Park Hospital, Surrey, United Kingdom

Background: The utility of bone marrow biopsy trephine (BMT) as a diagnostic tool in patients with fever of unknown origin (FUO) is a subject of controversy and debate. BMT has been shown to be safe and useful in patients with HIV/AIDS but its value in immunocompetent patients has not been sufficiently assessed. It's reported the use of diagnostic BMT as a rapid decision-making tool in patients with HIV/AIDS and FUO in the proper clinical setting. A BMT demonstrated infection-related evidence prior to positive bone marrow culture in 75% of cases. Special stains and blood cultures had similar diagnostic yield, but BMT offers faster results. Thus, this procedure assists in clinical decision-making and the refinement of treatment in a more timely manner.
Aims: determine the utility of Bone marrow biopsy in FUO patients.
Methods: We reviewed retrospectively the bone marrow biopsy results of the inpatients who underwent BMT from January 2010, to December 2016. Demographic, laboratory, diagnostic and outcome data were collected and retrospectively analyzed. We identified 31 patients who fulfilled the accepted classic Petersdorf criteria for FUO. The cohort included immunocompromise and immunocompetent patients.
Results: The BMT contributes to the diagnosis in only four cases (12.9%). In two patients (6%) the histology revealed the presence of granuloma and/or lymphohistiocytic aggregates; one secundary hemophagocytosis (3.2%) and one mastocytes infiltrate (3.2%). Six patients had a previous diagnosis of HIV/AIDS (19%). Sub analysis in HIV/AIDS patients revealed positive BMT culture in 2 of the patients (6,4%). Cultures demonstrated Mycobacterium tuberculosis and Mycobacterium avium intracellulare. There was one case in which a pathogen was grown in culture but that had a negative of 'direct examination'. The associations most likely related factor to contribute to the diagnosis in HIV/AIDS was male predominance (58% odds ratio [OR] 2.95; 95% CI, 1.19-4.25), clinical lymphadenopathy (OR 4.97; 95% CI, 1.90-2.44) or anemia (OR, 2.21; 95% CI, 1.26-3.84). Reactive myeloid hyperplasia was represented 15 cases (48%). Non- haematological diagnosis (lymphoma, Leukemia) was made on the exclusive bases of biopsy results.
Summary/Conclusions: Bone marrow examination is an integral part of investigation of FUO, however, morphological finding alone would not be sufficient to ascertain the diagnosis. In present study only two cases of established infections (Mycobacterium) were detected on bases of the marrow culture. Both were present in HIV/AIDS. These results are explained because a highly active antiretroviral therapy has reduced incidence of opportunistic infections. The percent of opportunistic infections diagnosed by BMT was very low and did not justify an invasive procedure. The presence of granulomas in trephine biopsy increases the likelihood of an aetiologic diagnosis in these patients. Bone marrow biopsy is still a useful ancillary procedure for establishing the diagnosis of FUO, only if used in the adequate context.

PB1894

THE OUTCOME OF PEDIATRIC CANCER PATIENTS ADMITTED TO THE INTENSIVE CARE UNIT OF A TERTIARY HOSPITAL IN GWANGJU-CHONNAM, KOREA

H. Kook[1,*], G. Kim[1], J.-S. Choi[1], H.-J. Cho[1], H.-J. Baek[1]
[1]Pediatrics, Chonnam National University Hwasun Hospital, Hwasun-gun, Korea, Republic Of

Background: Recent advances in supportive care have considerably improved the prognosis of pediatric cancer patients. However, the use of aggressive cancer treatment is also associated with complications and life-threatening events that result in admissions to the intensive care unit (ICU).
Aims: This study aimed to analyze the outcome of pediatric cancer patients admitted to the ICU.
Methods: A retrospective analysis of 84 ICU admissions of cancer patients <21 years old between May, 2004 and Aug, 2016 at Chonnam National University Hwasun Hospital (CNUHH) was undertaken. The risk factors for short-term outcome (survival at the time of discharge from the ICU) were analyzed. After excluding scheduled perioperative admissions, the records of 81 admissions (75 patients) were reviewed.
Results: Hematologic cancer patients represented 71.6% of admissions. The mean duration of ICU stay was 10.7 days. Respiratory failure (39.5%) and septic shock (17.8%) were the most frequent indications for ICU admissions. Overall mortality rate was 46.9%. The mortality for hematologic cancer was 51.7% as compared to 34.8% for solid cancer (P >0.05). Mortality for individual indication was as follows: bleeding, 66.7%; respiratory failure, 59.4%; systemic infection 57.5%, anterior mediastinal syndrome, 50%, neurologic disorders, 37.5%, renal disorder, 37.5%, and so on. ICU mortality after hematopoietic stem cell transplantation was 66.7%, mostly within 100 days post-transplant. The median Pediatric Risk of Mortality Score (PRISM) III score of survivors was lower than that of non-survivors (11.3±5.1 *vs* 19.9±10.9, P<0.001). The mortality rates were 70.3% and 27.3% in patients with high (>15 points) and low (≤15 points) PRISM III score, respectively (P<0.001). Mortality rate was significantly related to the presence and number of organ system dysfunction (P<0.01 and P<0.001, respectively), positive inotropic support (P<0.01), and mechanical ventilation (P<0.001). By using multivariate logistic regressions, the independent risk factors were mechanical ventilation (OR, 6.0; 95% CI, 1.7-21.3; P<0.01), and ≥3 organ system dysfunction (OR, 18.5; 95% CI, 4.4-77.0; P<0.001). Hematologic cancer patients had higher mean PRISM3 score (16.5±9.4 *vs* 12.2±8.6; P=0.51) and higher risk of sepsis (39.3% *vs* 13.0%; P<0.05) compared to solid cancer patients.
Summary/Conclusions: These results revealed the current status of ICU care for pediatric cancer patients in a tertiary hospital in Korea. Further improvement of supportive care and earlier effective intervention should be translated in gradual reduction in mortality rate in these population.

PB1895

EFFICACY AND SAFETY OF TIGECYCLINE IN FEBRILE NEUTROPENIC PATIENTS WITH HEMATOLOGIC MALIGNANCIES AND CARBAPENEM RESISTANCE: A MULTICENTRE RETROSPECTIVE STUDY FROM CHINESE PEOPLE

X. Bing[1,*], H. Lingli[2], C. Guoshu[3], L. Zhifeng[1], S. Pengcheng[4], G. Xutao[4], W. Yan[2], L. Jie[2], L. Jiabao[2], Z. Yong[1]
[1]The First Affiliated Hospital of Xiamen University, Xiamen, [2]Nanfang Hospital, Southern Medical University, Guangzhou, [3]Huizhou Municipal Central Hospital, huizhou, [4]Nanfang Hospital, Southern Medical University, Xiamen, China

Background: Tigecycline has broad spectrum activity against multidrug-resistant (MDR) bacteria, but few investigations of tigecycline in febrile neutropenic (FN) patients with malignancy are available.
Aims: This study attempts to investigate the efficacy and safety of tigecycline in FN and carbapenem resisant patients with hematologic malignancies.
Methods: The study of 109 patients with hematologic diseases and FN were retrospectively analyzed. They are unresponsive to carbapenems for 3~5 days before receiving tigecycline (loading dose 100 mg; then 50 mg every 12 hours). Clinical response to treatment was defined as clinical cure, improvement or failure. Meanwhile, the adverse events were documented.
Results: The median duration of neutropenia was 15 days (ranged from 1 to 83d). Out of 109 patients, 96 (88.1%) had respiratory infection, while 33 (30.3%) had bloodstream infection. The total response rate of tigecycline was 65.1%. The bacterial eradication rates and bacterial hypothetical eradication were 25.9% and 24.1%, respectively. The clinical effective rate was 85.7% when tigecycline was administered for more than 9 days, while just 48.3% when administered for less than 9 days (p<0.001). Patients with bloodstream infection got a worse efficacy than those without (41.2% *vs* 69.6%, *p=0.024*). For patients whose absolute neutrophil counts were less than 0.1×10^9/L, the clinical effective rate decreased obviously (59.8%, *vs*.86.4%, p=0.019). The side-effects were well tolerated. No lethal adverse events were observed.
Summary/Conclusions: Our results demonstrated tigecycline was effective and safe for patients unresponsive to carbapenems with FN, combination and prolonged duration of tigecycline is recommended, and these results need to be further studied.

PB1896

BONE MARROW CYTOLOGICAL CHARACTERIZATION OF PATIENTS WITH HIPERREACTIVE MALARIAL SPLENOMEGALY

E. De La Vega[1,*], F. Gómez-Aguado[1], M.T. Corcuera[2], M.D.M. Lago[3], M. Gasior[1], V. Jiménez[1]
[1]Hematología y Hemoterapia, [2]Microbiología, [3]Medicina Interna, Hospital Universitario La Paz, Madrid, Spain

Background: Hyperreactive malarial splenomegaly (HMS) is a common cause of massive splenomegaly in malarial-endemic areas. At present, diagnosis of patients with suspected HMS in tropical medicine departments of european hospitals is relatively frequent due to immigration and the return of missionaries and NGO workers after long periods in tropical countries.
Diagnostic protocols for HMS usually include a cytological study of bone marrow, because clinical similarities between HMS and lymphoproliferative disorders have been reported. However, there are no large series in the literature that estimate a bone marrow cytological standard associated to HMS. Another important issue is that patients with HMS are often multiinfected by other parasites, viruses and bacteria that may also induce splenomegaly.
Aims: The aim is to define the bone marrow cytological pattern of patients with confirmed HMS, as well as of HMS patients with associated viral (HIV, HBV, HCV) or parasitic diseases.

Methods: A retrospective cytological study of bone marrow aspirates from 95 patients with HMS (n=27), HMS+HIV (n=8), HMS+HCV/HBV (n=11) and HMS+intestinal parasitosis (n=49) has been performed.
Results: Bone marrow cellularity was normal in all the groups studied except in HMS+HIV patients, in which the cellularity was very diminished (statistically significant difference, p<0.01). Most frequent alterations observed in all samples (HMS and HMS+other entities) that could define the HMS-bone marrow cytological pattern, were: - Erythroid hyperplasia with dyserythropoiesis, which is reflected in a decreased myeloerythroid ratio. - Increased eosinophils percentage. - Increased lymphocytes percentage. - Increased plasma cells percentage and detection of Mott cells in a significant proportion of samples from all series (48.1% of HMS samples). Quantitative results for these variables are summarized in Table 1. Lymphocytosis was significantly increased in HMS+HBV/HCV bone marrow (p=0.04). Significant detection of atypical lymphocytes (>4%) varied widely between the groups, ranging from 14.8% of HMS bone marrows to 75.0% of HMS+HIV bone marrows (statistically significant difference, p<0.01). There was no lymphoma evidence in any case. No quantitative or qualitative alterations were detected in megakaryocytes, except for a slight decrease in HMS+HIV bone marrows (statistically non-significant difference) (Figure 1).

Table 1. Quantitative results (mean±standard deviation).

	Reference values	HMS	HMS+HIV	HMS+HBV/HCV	HMS+IP
Myelo:erytroid ratio	3.5:1	2.0:1±0.8	2.2:1±1.3	2.4:1±0.6	2.5:1±0.7
Eosinophils (%)	<5	12.4±10.0	8.6±4.9	9.4±8.9	12.3±8.3
Lymphocytes (%)	10-6	23.0±9.5	26.7±9.2	27.6±5.7	23.8±7.0
Plasma cells (%)	≤4	6.8±2.7	8.1±3.1	6.4±1.6	7.3±3.0

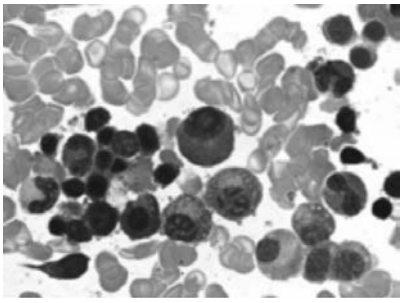

Figure 1.

Summary/Conclusions: As far as we know, this is the largest series of HMS bone marrow analyzed. Identification of common cytological findings in all the groups studied allows defining a characteristic cytological pattern for HMS. The reason for these findings could be related to an aberrant chronic immune response caused by a continuous exposure to malaria parasites. Only bone marrows of HIV coinfected patients present additional specific alterations (decreased cellularity and high proportion of atypical lymphocytes). Some authors hypothesize that HMS could eventually evolve to chronic lymphocytic leukemia, hairy cell leukemia or splenic lymphoma with villous lymphocytes, so a special follow-up would be advisable for those patients with a high proportion of atypical lymphocytes.

PB1897

ACUTE APPENDICITIS IN LEUKEMIA PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION DURING THE NEUTROPENIC PHASE

Q. Zhang[1,*], Q. Jiang[1], Y. Zhou[1], Q. Mai[1], K. Tsui[2], Z. Wei[2], J. Majaw[2], C. Zou[2], Y. Zhang[1], F. Huang[1], Z. Fan[1], J. Sun[1], Q. Liu[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, [2]First Clinical Medical College, Southern Medical University, Guangzhou, China

Background: Infectious complications arising from the gastrointestinal tract is common in neutropenic patients with hematologic malignances, especially during HSCT.
Aims: Sequential analysis of 776 HSCTs in single center, totally 10 cases of acute appendicitis were found out, the treatment and outcome were further analyzed.
Methods: The HSCT patients who occurred acute appendicitis during -10d~+60d in the Hematological Department of Nanfang Hospital from Jan. 2005 to July 2016 were analyzed. Patients were enrolled in our study based on the Modified Alvarado Scoring combined with ultrasonography (the MASS total score of 1-4: acute appendicitis very unlikely; Score 5-7: acute appendicitis probable; Score 8-10: acute appendicitis definite. We selected those cases with scores 5-10). And the follow-up lasted for 24 m.
Results: 776 HSCT patients were analyzed, in which 10 patients (7 male, 3 female) had acute appendicitis during -1d~+7d, which included two cases of sepsis. The median age was 18.5 (10-39) years of age. 7 patients were ALL and the other 3 were CML. All patients underwent allo-HSCT. 6 patients received conditioning regimen of IDA/TBI/CY/VP-16, and 4 others were treated with TBI/CY/VP-16/Ara-c, FA/TBI/CY/VP-16, Bu/Cy and Bu/Cy/Ara-c respectively. All the cases scored range from 5 to 10 of the MASS, and 6 patients showed positive findings on ultrasonography. All the patients had a mean value of neutrophil of 0.06×10^9/L (Table 1). 10/10 cases were cured with conservative therapy, mainly contained different kinds of full dose broad-spectrum antibiotics, such as piperacillin/ tazobactam, imipenem cilastatin, teicoplanin, meropenem, tigecycline, *et al.*. Within 24 m, 8 patients did not relapse, one patient died from gastrointestinal bleeding 2 m after without recurrence of appendicitis, while one patient relapsed 1 year later and was cured by appendectomy.

Table 1. Combined with the Modified Alvarado Scoring and ultrasonography to diagnose appendicitis during the neutropenic phase of HSCT.

	Symptoms*			Signs*			Total	Examination	Blood Routine Test	
Case	Migratory right ilia fossa pain	Anorexia	Nausea /vomit	Tenderness in right iliac fossa	Rebound tenderness	Elevated temperature	Score *	Ultrasound#	WBC (×10⁹/L)	NEU (×10⁹/L)
Case 1	1	1	1	2	1	1	7	-	0.09	0.03
Case 2	1	1	1	2	1	1	7	+	0.06	0.06
Case 3	1	1	0	2	1	1	7	-	0.06	0.06
Case 4	0	1	0	2	1	1	5	+	0.01	0.01
Case 5	1	1	0	2	1	1	6	+	0.12	0.01
Case 6	1	1	1	2	1	1	6	-	0.53	0.08
Case 7	1	1	1	2	1	1	7	+	0.17	0.02
Case 8	0	1	1	2	1	1	6	-	0.49	0.40
Case 9	1	0	0	2	1	1	5	+	0.05	0.01
Case 10	1	1	1	2	1	1	7	+	0.04	0.02

*Reference standard by the Modified Alvarado Scoring System, Total scores were 10, Score 1-4: acute appendicitis very unlikely; Score 5-7: acute appendicitis probable; Score 8-10: acute appendicitis definite. # "-": negative; "+": positive.

Summary/Conclusions: Acute appendicitis occurring during the neutropenic phase in HSCT patients could be diagnosed by the MASS and ultrasonography, and such cases could be cured by conservative therapy. This study could provide a further choice for the diagnosis and treatment of acute appendicitis in leukemia patients of HSCT.

PB1898

EPIDEMIOLOGY OF BLOODSTREAM INFECTIONS IN NEUTROPENIC AND NON-NEUTROPENIC PATIENTS WITH MALIGNANCY

N. Raja[1,2], S. Gupta[3,*], B. O'Neill[2]
[1]Pathology, [2]Microbiology, [3]Haematology, East Sussex Healthcare Trust, Hastings, United Kingdom

Background: Blood stream infections (BSI) in patients with malignancies remain associated with significant morbidity and mortality. The choice of an empirical antibiotic regimen is usually based on the local epidemiology of the microorganisms and their antibiotimicrobial susceptibility profile. Antimicrobial guidelines for the management of sepsis in cancer patients in East Sussex Healthcare Trust (ESHT) recommend piperacillin/tazobactam as monotherapy and gentamicin is added in case of septic shock. Vancomycin is also added as a first line therapy if there is a suspicion of central line sepsis. Alternative therapies are ceftazidime or meropenem plus aminoglycoside.
Aims: We intend to review the aetiology of BSI and check the effectiveness of the antibiotics used in ESHT in cancer patients.
Methods: This retrospective study was conducted at ESHT from January 2006 to December 2015. Demographic and laboratory data were collected from the Pathology information system.
Results: A total of 640 episodes of BSI occurred in 297 patients (159 male). Of the 297 patients, 239 had haematology malignancies while 54 had solid organ tumour. Four patients had both. The neutrophil count was <1 cells/10^9 in 383 episodes and majority of BSI occurred in this group. A total of 802 organisms (477 and 325 organisms from neutropenic and non-neutropenic respectively) were isolated. Of 802, 406 Gram positive and 386 Gram negative organisms were isolated. Seven Mycobacterium species and three *Candida* species were isolated. Most common organisms in neutropenic patients were Coagulase negative *Staphylococcus* (CoNS) (22%), *Klebsiella* species (14%), *Escherichia coli* (13%), *Streptococcus* species (10%), *Pseudomonas* species (10%), *Enterococcus* species (8%) and *Staphylococcus aureus* (4%). In non-neutropenic patients, CoNS (29%), *Escherichia coli* (11%), *Pseudomonas* species (8%), *Streptococcus* species (7%), and *Klebsiella* species (5%) were isolated. Twelve Glycopeptide resistant *Enterococci* were isolated. Four Methicillin resistant *Staphylococcus aureus* were isolated. In addition, 15 Extended Spectrum Beta-lactamase producing Gram negative bacilli were isolated. Among Gram negative organisms, more than 91% isolates were sensitive to piperacillin/tazobactam, ceftazidime and ciprofloxacin and higher sensitivity rates (>96%) were recorded in gentamicin and meropenem, Table1 summarises the effectiveness of antibiotics used.
Summary/Conclusions: This study highlights an on-going trend towards Gram positive organisms causing BSI in cancer patients. The antimicrobial regimens used in ESHT are highly effective against commonly isolated organisms. An early diagnosis and timely administration of appropriate antibiotics are imperative in managing BSI. The identification and the antimicrobial susceptibility of the microorganisms causing BSI in cancer patients remain important to develop antimicrobial treatment strategies, and to prevent the spread of antimicrobial resistance.

Table1. The sensitivity of antibiotic regimens used.

Antibiotics	Sensitivity rates	
	Neutropenic patients N=383	Non-neutropenic patients N=257
Piperacillin/tazobactam plus gentamicin	98%	99%
Meropenem plus gentamicin	99%	100%
Ceftazidime plus gentamicin	99%	99%
Ciprofloxacin plus gentamicin	98%	99%

PB1899

CHANGING TREND IN LOCAL BACTERIAL EPIDEMIOLOGY: EXPERIENCE IN ACUTE LEUKEMIA PATIENTS HOSPITALIZED IN SINGLE HEMATOLOGY UNIT

C. Buquicchio[1,*], L. Ciuffreda[1], G. De Santis[1], C. Germano[1], M. Leo[1], M.T. Santeramo[1], R. Miccolis[1], G. Tarantini[1]
[1]Ematologia, SC Ematologia con trapianto, Barletta, Italy

Background: The intense chemotherapic regimens and hypometilant agents to treat acute leukemia induce prolonged neutropenia with high risk of infections.
Aims: To analize local microbial epidemiology we studied patients admitted to our ward.
Methods: All 100 cases of Acute Leukemia (AL) admitted in our ward from august 2013 to February 2017 received prophylactic antibacterial therapy with fluoroquinolones and were analized for weekly routine tissue colture screening and serial blood colture for fever. Six patients were Lymphoid AL and 94 were Myeloid AL. 41 patients were not elegible for intensive chemotherapy(for age and comorbidities) and were treated with hypometilant agents, while 59 were younger than 65 years and were treated with induction /consolidation chemotherapy 3 plus 7 regimen. Median age was 58 years with range from 27 to 88 years old.
Results: We found 28 patients (28%) bacterial septic shock during fever, of which 20 cases gram negative (71%) in particular 65% E.Coli, 15% Enterobacter, 10% Klembsiella, 5% Stenotrophomonas, 5% Pseudomonas; while 8 patients(29%) had a gram positive septic shock (S.Haemoliticus 38%, S.capitis 25%, S. hominis 25%, S epidermidis 12%). During intensive chemotherapy and prolonged severe neutropenia we took over the major incidence of septic shock (23 patients 82%) than hypometilant treatment in particular decitabine (5 patients 18%). During 2014 we had 3 mortal septic shock for multiresistant gram- klembsiella and Pseudomonas. Since than we adopted in our ward, isolation of patients with gram negative (klembsiella or pseudomonas)tissue colture positive, hygenic and sanitary practices with closing room for 48 hours and hand disinfection before entering and after leaving any patients room.We noticed a change of bacterial infections incidence in these 3 years in our ward.:reduction klembsiella /pseudomonas multiresistant infections and emergency of E.coli and Staphilococcus septic shock not multiresistant.
Summary/Conclusions: More epidemiological analysis in several haematological ward are necessary to understand if it is a changing local microbial epidemiology or is the different management of neutropenic patients with acute leukemia and/or a different antimicrobial strategy to determine this changing trend.

PB1900

UK SINGLE-CENTRE SERVICE EVALUATION TO DESCRIBE THE IMPACT ON HEALTHCARE RESOURCE USE OF LOCAL ANTIFUNGAL PROPHYLAXIS AND TREATMENT PROTOCOLS IN THE MANAGEMENT OF HIGH-RISK PATIENTS WITH NEUTROPENIA

D. Furby[1,*], H. Ahir[2], G. Nock[3], E. Taymor[2]
[1]Poole Hospital, Poole Hospital NHS Foundation Trust, Poole, [2]Merck Sharp & Dohme Ltd, Merck Sharp & Dohme Ltd, Hoddesdon, [3]pH Associates, pH Associates, Marlow, United Kingdom

Background: Patients with neutropenia, including those with haematologic malignancies, are at high risk of invasive fungal infections (IFI). Pre-2014, there were no formal written guidelines but the guidance at Poole Hospital NHS Foundation Trust specified the use of posaconazole oral suspension for primary prophylaxis in all high-risk patients except those with acute lymphoblastic leukaemia (ALL). In 2014 formal guideline changes included the introduction of the tablet formulation of posaconazole, use of micafungin as first line empirical therapy and a focus towards improving diagnostics to guide management. MSD Ltd. has developed the Fungal Service Evaluation Tool (FSET), a secure database and analysis tool, to support UK clinicians managing patients at risk of breakthrough IFI (BIFI) to evaluate their antifungal management.
Aims: This service evaluation aimed to utilise the FSET to evaluate the impact of the antifungal management guidelines on healthcare resource utilisation associated with patients at risk of a BIFI.
Methods: An interim analysis of high-risk adult patients with prolonged neutropenia aged ≥18 years at initiation of antifungal prophylaxis/treatment was carried out. Retrospective data on patient characteristics, antifungal prophylaxis and treatment, IFI-related diagnostic tests, hospital attendance/admission during antifungal prophylaxis were collected for 12-month periods before and after 2014 (Cohort 1: 2013; Cohort 2: 2015). Anonymised data was entered into the FSET and this data was analysed using descriptive statistics.
Results: The evaluation included 24 patients in Cohort 1 (median age 66.8 [interquartile range (IQR): 47.5–72.2] years; 16 [67%] male; 5 [21%] ALL) and 22 patients in Cohort 2 (median age 66.8 [IQR: 51.7–73.4] years; 13 [59%] male; 1 [5%] ALL). At least one line of antifungal prophylaxis was recorded in 22 (92%) patients in Cohort 1 and 17 (71%) in Cohort 2. Posaconazole was the most commonly prescribed antifungal in Cohort 1 (18/24 [75%]) and Cohort 2 (17/22 [71%]). Other agents used included liposomal amphotericin B, fluconazole, and itraconazole. There were no patients in Cohort 1 and 2 (9%) patients in Cohort 2 (overall 4%) who experienced a BIFI: 1 was defined as confirmed and 1 as suspected. The mean 12 month costs per patient for all resource utilisation (including antifungal drug costs, hospitalisation costs [including admissions and attendances], investigations and tests) was £28,903 in Cohort 1 and £21,934 in Cohort 2 (Figure 1). Hospitalisation costs were a key determinant of overall costs, which is common in the management of people with complex underlying disease. There were 4 (17%) patients in Cohort 1 and 1 (5%) in Cohort 2 who had a period of ITU associated stay, which typically has greater costs than general wards. The most common investigations/tests were blood cultures (Cohort 1: mean 13.8; Cohort 2: mean 10.7) and chest x-ray (Cohort 1: mean 4.0; Cohort 2: mean 2.5), which are in-line with routine clinical practice. Once implemented, the guideline was adhered to in the management of 19 patients (86%) in Cohort 2.

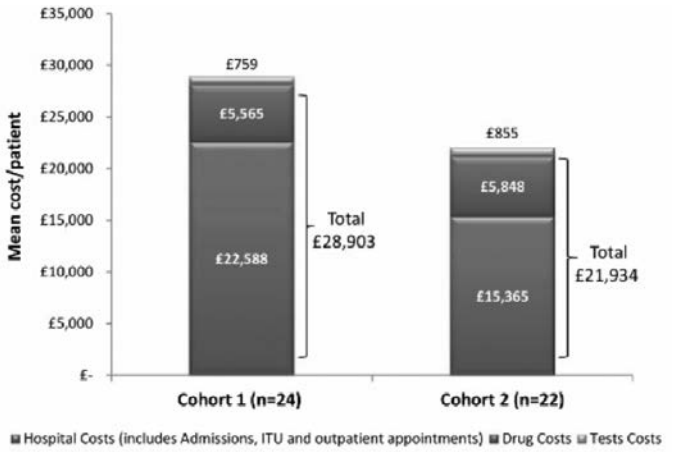

Figure 1. Breakdown of mean 12 month resource utilisation costs for cohorts 1 and 2.

Summary/Conclusions: These data show that rates of breakthrough IFI are low in complex patients receiving antifungal prophylaxis/treatment. Furthermore, the results in Cohort 2 indicate that the switch to recommending posaconazole tablets did not result in an increase in the mean cost per patient of antifungal prophylaxis and shows a lower overall mean cost per patient. A larger cohort study over a longer period is warranted to confirm these findings.

Iron metabolism, deficiency and overload

PB1901

REAL-LIFE FEASIBILITY OF AN IRON CHELATION PROGRAM WITH DEFERASIROX IN MYELODYSPLASIA AND OTHER ACQUIRED CHRONIC ANEMIAS: A SINGLE CENTRE EXPERIENCE

G. Bertani[1,*], M. Riva[1], E.B. Volpato[1], E. Ravano[1], I. Cuppari[1], A. Mazza[1], P. Usardi[1], R. Cairoli[1]
[1]Haematology, Ospedale Niguarda Ca' Granda, Milano, Italy

Background: Prolonged red blood cell (RBC) transfusion support in patients affected by myelodysplastic syndrome (MDS) and other chronic anemias may cause vital organs damage due to accumulation of non-transferrin-bound iron with consequent increased oxidative stress. Retrospective studies have shown that iron chelation may prevent aforementioned mechanisms and improve survival in low-risk MDS patients. Iron chelation is usually recommended in patients who received at least 20 RBC units and/or have a serum ferritin level of 1000 ng/ml or higher. Deferasirox, an oral iron chelator, has widely replaced the use of deferioxamine, due to its greater manageability, especially in the elderly. However, an high dropout rate of approximately 50% of patients within one year was observed in the majority of clinical studies, the leading cause of discontinuation being gastrointestinal (G.I.) and renal toxicity and skin rash.
Aims: We aimed at evaluating the real-life feasibility of a program of prolonged iron chelation in a population of acquired chronic anemia patients. Thus, we performed a retrospective analysis to evaluate which is the percentage of patients who in our centre actually receive and tolerate deferasirox treatment, among the cohort of eligible patients.
Methods: Deferasirox treatment is considered at our centre in patients affected by MDS or other forms of chronic anemia (excluded chronic bleeding) who fullfill criteria for iron chelation (high transfusion burden, *i.e.* ≥20 RBC units and/or a serum ferritin ≥1000 ng/ml). Starting dose is usually 10 mg/kg, titrated up to 20-30 mg/kg as tolerated. The cohort of patients transfused at our centre during 2015 and 2016 was considered for analysis. Causes of unsuitability and of treatment discontinuation were extracted from our database.
Results: Our cohort consisted of 58 patients, mainly affected by MDS (45 pts); other diagnosis were myelofibrosis (6 pts), NHL (2) and multifactorial anemia, not related to blood cancer (7). Only 38 out of 58 potentially eligible patients were assigned to iron chelation (see the Figure 1). The leading cause of ineligibility in our cohort were a reduced life expectancy (5 pts), due to the hematologic disease itself or to comorbodities, and pre-exisiting renal failure (4). Importantly, in 6 cases patients were not offered iron chelation without a specific clinical reason: half of them (3/6) were non-MDS patients. Furthermore, 13/38 patients had to interrupt the treatment, due to toxicity (mainly renal failure, followed by gastrointestinal toxicity, see flow-chart). Overall, 25/58 (43%) potentially eligible patients, *i.e.* heavily transfused patients, initiate and continue an iron chelation program at our centre. The main cause for treatment discontinuation in our cohort was renal failure, while we had less difficulties in managing G.I. adverse events. Renal toxicity of deferasirox is known to be reversibile; however, in patients with pre-existing compromise and those who concurrently take nephrotoxic drugs, treatment may be difficult to carry on.

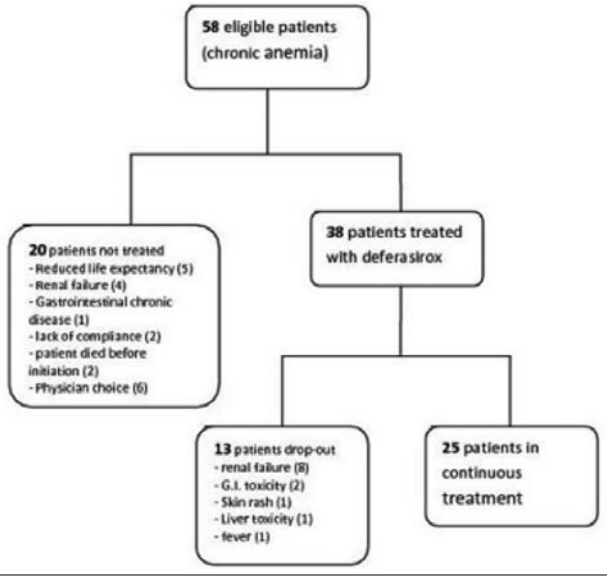

Figure 1.

Summary/Conclusions: Our data are in line with literature. However, there is still room for improvement, especially in the category of non-MDS patients, who are often under-treated. Furthermore, the introduction of a new formulation of deferasirox, which is forthcoming, may hopefully reduce G.I. toxicity and improve tolerance and patients adherence to therapy.

PB1902

NONINVASIVE TRANSCUTANEOUS SPOT-CHECKING OF TOTAL HEMOGLOBIN FOR THE SCREENING OF ANEMIA IN CAMBODIAN CHILDREN FROM REMOTE RURAL AREAS

J. Perez De Oteyza[1,2,*], L. Fernandez de la Fuente[2], C. Montero[1], L. Trives[2], A. Jayo[3], R. Guiote[2], V. Benito[2], B. Santos[2], A. Rodriguez[2], J. Marin[2], L. Sierra[2], S.P. Gonzalez[2], E. Martinez[2], J. Rodriguez[2], A. Perez[2], A.I. Sanz[2], X. Santos Heredero[2]
[1]Hematology, Hospital Universitario Madrid Sanchinarro, [2]Clinical Sciences, [3]Basic Sciences, Facultad de Medicina, Universidad CEU San Pablo, Madrid, Spain

Background: Previous studies have reported a high prevalence of anemia among school-aged children from Cambodia, ranging from 21 to 64%. Although iron deficiency accounts for the majority of cases, additional nutritional and non-nutritional etiologies have been identified. Children living in rural or remote areas, with limited access to health facilities, are at high-risk of developing anemia, and therefore, painless, fast, and reduced cost screening tests are needed.
Aims: The aim of our study is to evaluate the role of a portable device for transcutaneous noninvasive spot-checking of total hemoglobin (SpHb) in children living in remote locations.
Methods: Transcutaneous noninvasive spot-checking of total hemoglobin (SpHb) was performed in children attending summer-school camps at 12 different locations in Cambodia. SpHb was measured in fingertips by using size adapted optic sensors. For the purpose of the study, three age groups were defined as follows: Group 1=less than 5 years, group 2=5 to 11 years, and group 3=11 to 14 years.
Results: A total of 476 otherwise healthy children were analyzed. Mean SpHb value was 11.9 ±0.93 gr/dl (range 9-16 gr/dl). Overall, the prevalence of anemia in the entire population was 34.5%. Anemia was present in 5/31 (16.1%) of the children within group 1, 97/189 (33,9%) in group 2, and 54/81 (40%) in group 3. (p=0.039, two sided Pearson's Chi square). There were no differences in the prevalence of anemia by gender in groups 1 and 2. In group 3, anemia was significantly more prevalent in females 32/65 (49,2%) than in males 22/48 (31,4%), p=0.035.
Summary/Conclusions: Taken together, our results demonstrate the feasibility of noninvasive transcutaneous spot-checking of total hemoglobin (SpHb) for the screening of anemia in children from remote rural areas with limited access to health services. Our results also confirm the high prevalence of anemia in this population.

PB1903

IRON DEFICIENCY ANEMIA IN INFANTS AND YOUNG CHILDREN

S.K. Park[1,*], S.K. Kim[2], E.Y. Joo[2]
[1]pediatrics, Ulsan University Hospital, Ulsan, [2]pediatrics, Inha University college of medicine, Incheon, Korea, Republic Of

Background: Iron deficiency anemia in infants and young children is easy to be underdiagnosed. Anemia and iron deficiency are usually corrected after aged 2-3 years old, but it causes complications. There is an association between IDA and impaired neurocognitive function and exercise intorance, even after treatment of IDA. Therefore, preventing the progression of iron deficiency is especially important during infancy and early childhood, when increased vulnerability is associated with rapid growth and development, especially of the brain.
Aims: To detect iron deficiency anemia early and to reduce the adverse impact by IDA, we assessed the characteristics of infants and young children with IDA, those at risk for IDA and those exhibiting associated characteristics of severe anemia.
Methods: Among 1,782 children with IDA aged 6 months to 18 years-old, we retrospectively analyzed medical records and laboratory data of 1,361 subjects aged 6–23 months with IDA who had been diagnosed between 1996 and 2013. We excluded patients with CRP ≥5 mg/dL.
Results: IDA was predominant in boys (2.14:1) during infancy and young childhood. Peak incidence was at 9 to 12 months of age. Only 7% of subjects were brought to the hospital with symptoms and/or signs of IDA, while 23.6% in subjects with severe IDA. LBW infants with IDA shows low adherence with iron supplementation. In a multivariate analysis, risk factors of severe anemia in infants included prolonged breastfeeding without iron fortification [odds ratio (OR) 5.70] and low birth weight (OR 6.49).
Summary/Conclusions: Many clinicians did not consider IDA as a real problem, so many children with IDA were not followed up. LBW infants need more attention to increase adherence of iron supplementation. For early detection of IDA, nutritional assessment should be evaluated in every infants and iron batteries in high risk infants (LBW infants, prolonged breastfeeding, picky eater and/or symptoms of IDA) at health screening visit.

PB1904

THE ROLE OF ZINC PROTOPORPHYRIN IN THE DIAGNOSIS OF SIDEROPENIC ANEMIA

T. Nascimento[1,*], S. Marini[1], D. Mota [1], P. Bernardo[1], L. Relvas [1], A.C. Oliveira [1], E. Cunha [1], J. Pereira[1], C. Bento[1], T. Magalhães Maia[1], M.L. Ribeiro[1]
[1]Serviço de Hematologia Clínica , Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Sideropenic anemia (IDA) is the main cause of anemia worldwide. Even though, its diagnosis is quite straightforward with the use of red blood cell indices, peripheral blood smear (PBS) and ferritin measurements, there are still some pitfalls, namely in the presence of inflammation. The chelation of iron by protoporphyrin constitutes the final reaction of heme biosynthesis. In the absence of iron, zinc becomes an alternative substrate for ferrochelatase leading to the formation of zinc protoporphyrin (ZPP). This compound can be quantified by fluorometry in blood samples, proving itself as a useful and easy parameter for the diagnosis of IDA. However, this technique is not broadly used in the clinical practice.
Aims: Determine the cut-off value of ZPP for the diagnosis of IDA. Evaluate the value of ZPP for the differential diagnosis between IDA and anemia due to inflammatory diseases (AID).
Methods: We have analyzed in our lab, from 1st to 15thFebruary 2017, all the consecutive samples (pediatric and adult) with anemia (as defined by WHO) which had sedimentation rate (SR) and serum ferritin evaluations.
We have defined three different groups: IDA: Anemia and Ferritin <20µg/L; AID: Anemia, Ferritin >20µg/L and SR>20mm/h; Group control (GC): Normal levels of Hb adjusted by age and sex, as defined by WHO, Ferritin 20-120µg/L and SR<20mm/h. ZPP measurement was performed by hematofluorometry (AVIV, Biomedica, Inc). Data were analyzed by SPSS v20.0 using Wilcoxon W and Man-Whitney to examine differences between groups and receiver-operating characteristic (ROC) analysis to determine the cut-off values of ZPP. We considered statistically significant a p-value <0.05.
Results: We have identified 204 samples that fulfilled the inclusion criteria: 104 with IDA, 51 with AID and 49 from control patients. IDA group: 73% female (F); mean age 32.3y in F [1.1-78], 28y in males (M) [1-78]; mean Hb was 10.6g/dL [SD 1.4]; mean ferritin was 9.3 ug/L [SD 4.85] and ZPP was 214.1 µmol [SD 121.3]; mean SR was 20.0 mm/h [SD12.9]. AID group: 75% F; mean age 47y in F [2-91] and 22y in M [1-85]. Mean Hb 11.0 g/dL [SD 1.2]; mean ferritin 150.3 µg/L[SD246.2] and ZPP 136.7 µmol [SD 107.8]; mean SR 47mm/h [SD 21]. GC: 69.4% F; mean age 44,8y in F [1.1-79], and 37y in M [2-65 years]; mean Hb 13.8 g/dl [SD 0.9]; mean ferritin 71.9ug/L [SD 49.9] and ZPP 78.6 µmol [SD 26.6]; mean SR 14mm/h [SD 4]. The mean serum ZPP in IDA and AID was significantly higher than in GC (95% CI; p<0.0005). The ROC analysis showed 83.7% sensitivity and 85% of specificity to identify IDA for ZPP ≥100.3 µmol (W=0.933) and 69% sensitivity and 70% of specificity to identify AID for ZPP ≥140 µmol (W=0.749) when compared with GC.
Summary/Conclusions: We have concluded that ZPP is a valid, quick, easy and cheap parameter to diagnose IDA in clinical practice, and we have defined in our cohort of patients a ZPP cut off of ≥100.3µmol as diagnostic of IDA with 83.7% sensitivity and 85% of specificity, independent of age. In AID patients we found a cut-off value of ≥140µmol, but with a low sensitivity and specificity. In our study ZPP was not a reliable method to differentiate IDA from AID. This could be due to a sample selection bias (since clinical data were missing and the number of patient with AID was substantially lower than with IDA). It would be important to enlarge the AID sample in order to obtain a more reliable result. Since ZPP measurement can be performed in capillary blood and it is a very quick and cheap method to diagnose IDA, this could be a powerful tool in underdeveloped countries.

PB1905

HYPERFERRITINEMIA AND SERUM INFLAMMATORY CYTOKINES IN 71 ADULTS WITH NEWLY DIAGNOSED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS ASSOCIATED WITH HEMATOLOGICAL MALIGNANCY

M. Machaczka[1,2,*], F. Lorenz[3], E. Pawłowicz[4], M. Gajewski[5], M. Wolan[2], M. Klimkowska[6]
[1]Hematology Center Karolinska, Karolinska University Hospital Huddinge, Stockholm, Sweden, [2]Medical Faculty, University of Rzeszow, Rzeszow, Poland, [3]Department of Radiation Sciences, Section of Hematology, Umeå University, Umeå, Sweden, [4]Medical University of Łódź, Łódź, [5]Medical University of Silesia, Katowice, Poland, [6]Department of Clinical Pathology and Cytology, Karolinska University Hospital Huddinge, Stockholm, Sweden

Background: Hemophagocytic lymphohistiocytosis (HLH) is an underdiagnosed but life-threatening syndrome of hyperinflammation which in adults is often caused by hematological malignancies. Release of inflammatory cytokines in HLH induces immune cells and cytokine production that cumulates in cytokine storm and hyperinflammation. Hyperferritinemia ≥500 µg/L is a diagnostic criterion for HLH. Prevalence of hyperferritinemia in HLH in the adult population is much less established than in children.
Aims: The aim of the present study was to evaluate the frequency and extent of hyperferritinemia as well as serum concentrations of selected inflammatory cytokines at the time of diagnosis of hematological malignancy-associated HLH (hM-HLH) in adults.
Methods: The study included 71 adults with hM-HLH, aged 22–84 years, and diagnosed between 2009 and 2016. Hematological malignancy was defined as a neoplasm of lymphoid or myeloid origin. In all studied patients, the diagnosis of HLH was based on the HLH-2004 criteria. Since the majority of patients in this study had severe lymphopenia, we decided to not perform functional analyses of NK-cells for HLH diagnosis. Thus, we included in this analysis all patients with hematological malignancies and suspected HLH who fulfilled at least four of seven HLH-2004 criteria as well as at least two of three additional features: sIL-2Rα ≥2400 U/mL, hemophagocytosis in BM, and hyperferritinemia ≥10,000 µg/L. Serum concentrations of inflammatory cytokines IL-1β, IL-6, IL-8, IL-10 and TNF-α were analyzed using chemiluminescence (IMMULITE® One, DPC Siemens). Serum levels of sIL-2Rα were determined by ELISA, using the quantitative 'sandwich' enzyme immunoassay, on the IMMULITE® 1000 Immunoassay System (DPC Siemens).
Results: Lymphoid malignancy was diagnosed in 42 patients and myeloid malignancy in 29 patients. Fifty-four (76%) patients developed HLH as a first manifestation of an unknown malignancy, during progressive disease, or at malignancy relapse. The remaining 24% of patients developed HLH during chemotherapy. Serum ferritin concentration (ref.: 30–350 µg/L) at the time of hM-HLH diagnosis was elevated in all but one patient (70/71, 98%). Mean ferritinemia was 37,281±84,440 µg/L, median value 14,727 µg/L, and ferritinemia range 96–645,291 µg/L. As HLH-2004 criterion, hyperferritinemia ≥500 µg/L was present in 69 of 71 patients (97%) at the time of HLH diagnosis. Hyperferritinemia of ≥2000 µg/L was noted in 67 (94%) patients, hyperferritinemia of ≥5000 µg/L in 56 (79%) patients, and hyperferritinemia of ≥10,000 µg/L occured in 42 (59%) patients. Serum levels of sIL-2Rα (sCD25) were measured in 69/71 patients, of whom 91% (63/69) had values ≥2400 U/mL. Moreover, in 3 more patients sIL-2Rα was clearly elevated to 2179, 2233, and 2345 U/mL, respectively. Concentrations of TNF-α, IL-6, and IL-10 in serum were each elevated in over 85% of the examined hM-HLH patients. IL-8 concentration was increased in half of all tested patients at the time of HLH diagnosis. However, IL-1β concentration was above reference range only in 12% of patients (7 of 58). Results of the inflammatory cytokine analyses in patients with newly diagnosed hM-HLH are presented in Table 1.

Table 1. Inflammatory cytokines in patients with newly diagnosed hM-HLH.

Inflammatory cytokine	Reference range	Number of tested patients	Number (%) of patients with elevated cytokine concentration	Elevated cytokine concentration		
				range	mean	median
IL-1β	<5 ng/L	58	7 (12%)	5.5 – 40	15.1	11.5
IL-6	<5 ng/L	57	50 (88%)	5.2 – 10,101	505	70.8
IL-8	<60 ng/L	58	29 (50%)	64 – 6,256	680	184
IL-10	<5 ng/L	39	38 (97%)	5.9 – 10,001	710	80.0
TNF-α	<12 ng/L	50	43 (86%)	12.5 – 173	45.1	27.6

Summary/Conclusions: Hyperferritinemia at the time of HLH diagnosis was common in Swedish adult patients with hM-HLH. Hyperferritinemia ≥500 µg/L was present in vast majority (97%) of them. We would like to emphasize that serum ferritin level fluctuates and can differ significantly from one day to another. Ferritinemia should be repeatedly measured in cases of suspected HLH. Serum concentrations of TNF-α, IL-6, IL-8, and IL-10 were frequently elevated in the examined hM-HLH patients and these can become important markers supporting HLH diagnosis in equivocal cases. On the other hand, IL-1β seems to be less usefull in confirming a cytokine storm in this patient group.

PB1906

REDUCING UNNECESSARY BLOOD FILMS USING AN IRON DEFICIENCY ALGORITHM

R. O'Toole[1,*]
[1]Haematology, Wellington SCL, Wellington, New Zealand

Background: In 2015, Wellington SCL (WSCL) was selected to provide integrated laboratory services in the Wellington region, New Zealand (NZ). This involved merging services from previous community laboratory Aotea Pathology Ltd. (APL) with the three regional hospital based District Health Boards (DHB) laboratories - Capital & Coast (CCDHB), Hutt Valley and Wairarapa. On the 1st of November 2015, WSCL would launch its new integrated service with a merged workforce, new technology, processes and procedures. Considered to be the biggest laboratory integration project undertaken in NZ, every effort needed to be made to reduce the workload without compromising patient care.
Aims: In the Haematology laboratory, one of the most common triggers for

blood films are iron deficient pictures with the characteristic finding of reduced Haemoglobin (Hb), MCV and MCH. Above certain thresholds, the blood film adds little or no value to the CBC in these patients, apart from correlating with the iron studies results or suggesting iron studies when unavailable. One initiative used to manage the workload was based on this logic and aimed to reduce the blood film review rate using IT3000 technology (Roche).
Methods: An algorithm was designed in IT3000 to encourage testing and treatment for iron deficiency using a series of automated educational comments, while minimising unnecessary laboratory work. The impact that this algorithm had at WSCL was investigated by retrospective analysis of all the patient results from 1st November 2015 to the 1st of May 2016.
Results: In the first six months of operation, WSCL performed 232,192 CBCs and 30,204 blood films with an average review rate of 13.01%. Had this algorithm not been employed, 2,434 extra blood films would have been reviewed, bringing the review rate up to 14.05%.
Summary/Conclusions: Incorporation of an algorithm specific for iron deficiency in IT3000 has significantly reduced the review rate without any negative impact on patient care.

THE RELATIONSHIP ENDOTHELIAL MICROPARTICLES AND ASYMMETRIC DIMETIL ARGININE IN CHILDREN WITH IRON DEFICIENCY AND IRON DEFICIENCY ANEMIA

E. Kaygı Tartıcı[1], Y. Altuner Torun[2,*], C. Karakukucu[3], S. Celik[4], H.T. Hormet Oz[5]
[1]Pediatrics, [2]Pediatric Hematology, [3]Biochemistry, [4]Pediatric Cardiology, [5]Microbiology, Medical Health University, Kayseri, Turkey

Background: Iron deficiency anemia and iron deficiency without anemia increase the risk of atherosclerosis by increasing oxidative stress and inflammation. Endothelial dysfunction is an important factor of the pathogenesis of atherosclerosis.
Aims: Endothelial micro particles (EMPs) are considered as markers of endothelial dysfunction. Asymmetric dimetil arginine (ADMA) is known as another marker of endothelial dysfunction. In this study; we aimed to evaluate circulating EMPs and ADMA in children with iron deficiency and iron deficiency anemia and to disclose iron deficiency with the strongest relation with EMPs, ADMA and carotid atherosclerosis.
Methods: This study included 30 children with iron deficiency anemia, 30 children with iron deficiency without anemia and 30 healthy children whose anthropometrics measurements were recorded. Hemoglobin, serum iron level, iron binding capacity, ferritin, and lipid profile were studied. Circulating EMPs (CD144, CD146, and CD105) were measured by flow cytometry. ADMA was measured by ELİSA. The carotid artery intima media thickness (CIMT) and left ventricular mass index (LVMI) were measured using echocardiography.
Results: CD144 and CD105 EMP levels were lower in the iron deficiency without anemia group than in the control group and statically lower than in the iron deficiency anemia group ($p<0.05$). There were no significant differences in ADMA level between groups. Any significant variety in ADMA level was not observed between groups. CIMT was negative correlated with ferritin and high density lipoprotein and positive correlated with body weight.
Summary/Conclusions: In this study**,** endothelial dysfunction which occurs as a result of iron deficiency were observed. According to our result, CD144 and CD105 EMP levels in the iron deficiency without anemia group were lower than the iron deficiency anemia and control group; these levels in iron deficiency anemia group were higher than control group. In addition, when the level of ferritin has decreased, CIMT has increased. This study show that CD144 and CD105 may be related to endothelial dysfunction which occurs by iron deficiency.

PB1908

INVESTIGATION OF IRON METABOLISM FOR REGULATING MEGAKARYOPOIESIS AND PLATELET COUNT ACCORDING TO THE MECHANISMS OF ANEMIA

S. Kim[1], S.Y. Cho[1,*], T.S. Park[1]
[1]Kyung Hee University Hospital, Seoul, Korea, Republic Of

Background: Iron deficiency anemia (IDA) is characterized by depletion of total body iron stores. By contrast, chronic inflammation makes iron unavailable for hematopoiesis through a cytokine-mediated cascade, resulting in anemia of chronic disease (AOC). However, the laboratory data regarding the regulatory role of iron metabolism on platelet count has not been fully discussed yet.
Aims: In this study, we investigated the relationship between iron status and platelet production according to different anemic mechanisms representing different iron metabolisms.
Methods: The study included total of 759 blood specimens from 537 different patients. The complete blood count with various CBC index were measured using Advia 2120 (Siemens, USA). Biochemical indexes including iron level were estimated using Toshiba chemical analyzer (Toshiba, Japan).
Results: We found a significant relationship between platelet count and serum iron level in AOC group ($p<0.27$), whereas there was no correlation in IDA group. In AOC group, platelet count was significantly correlated to serum iron level only in AOC group with decreased serum iron level ($p<0.0001$), unlike AOC group with normal serum iron level.
Summary/Conclusions: Reactive thrombocytosis in inflammatory states occurs by cytokine cascades involving interleukin-6 and thrombopoietin in AOC. Moreover, iron deficiency in AOC involves upregulated hepcidin production induced by increased inflammatory cytokines. It can cause increased iron sequestration in macrophage and decreased iron absorption for bone marrow. The condition of decreased megakaryocytic iron supply makes megakaryocytes with higher ploidy which can release more platelets than lower ploidy. These two features may enhance thrombocytosis in patients of AOC with decreased iron level. In the future, the further study should be performed to elucidate underlying mechanism involving the tight regulation between iron metabolism and megakaryopoiesis in anemic patients.

SOLUBLE TRANSFERRIN RECEPTOR LEVELS OF APPARENTLY HEALTH ADULTS IN PORT HARCOURT NIGERIA

C. Efobi[1,*], B. Nwogo[2], I. Onyiaorah[3], O.A. Ejele[4]
[1]haematology, chukwuemeka Odumegwu Ojukwu University, Awka, [2]haematology, university of Benin, benin city, [3]histopathology, nnamdi azikiwe university, nnewi, [4]hematology, university of port harcourt, port harcourt, Nigeria

Background: Soluble transferrin receptor (sTfR) is an early marker of tissue iron deficiency before onset of anaemia. sTfR is one of the noninvasive tools for early diagnosis of iron deficiency anaemia, which is one of the most prevalent causes of anaemia in our environment. However, there is not established reference range of this diagnostic marker sTfR in our environment. There is an important need to devise a screening tool for early detection of iron deficiency before onset of anaemia.
Aims: To determine the sTfR levels of apparently healthy adults in Port Harcourt, Nigeria, determine the reference range of sTfR in the study population.
Methods: This is a descriptive cross sectional study conducted at the University of Port Harcourt Teaching Hospital. one hundred and fifty participants (107 males and 43 females) who satisfied the inclusion criteria were enrolled in this study. The ages of the study population were grouped into four: 21-30, 31-40, 41-50, 51-60. Full blood count and sTfR concentration were assyed on anticoagulated blood samples using a 3- part autoanalyser (sysmex -KX2IN) and Human ELISA kit by biovendor respectively. The results were analysed using SPSS version 21. P value of <0.05 was considered significant.
Results: The mean sTfR concentration of the study population was 0.89±0.46ug/mL with a range of 0.3- 3.05ug/ml. The mean value of sTfR for males and females were 0.92±0.49ug/ml and 0.82±0.37ug/ml. The mean sTfR for age group 21-30 was 0.88+/-0.48ug/ml and 0.80+/-0.47ug/ml for males and females respectively, while the mean sTfR for age group 51- 60 was 0.98+/-0.53 ug/ml and 0.97+/-0.13ug/ml for males and females respectively. The mean sTfR levels did not differ significantly for age and sex.
Summary/Conclusions: This is the first cross sectional study in our environment to determine reference value of sTfR levels in healthy adults in Port harcourt. This reference value was established as 0.3-3-05ug/ml. This study found no statistically significant relationship between different ages and sexes.

ROLE OF PRO-PHAGOCYTIC CALRETICULIN AND ANTI-PHAGOCYTIC CD47 IN MDS AND MPN MODELS TREATED WITH AZACYTIDINE OR RUXOLITINIB

K. Boasman[1,*], C. Bridle[2], M.J. Simmonds[1], C.R. Rinaldi[1]
[1]School of life Sciences, Collage of Science, [2]Lincoln Institute of Health, University of Lincoln, Lincoln, United Kingdom

Background: Myelodysplastic syndrome (MDS) and Myeloproliferative neoplasms (MPN) are clonal myeloid disorders with the tendency to progress into acute myeloid leukaemia. Previous studies in solid tumours have shown an increase in expression of both pro-phagocytic calreticulin (CALR) and anti-phagocytic CD47, as they act in response to one another, reflecting a possible apoptosis *vs* survival mechanism in response to chemotherapy.
Aims: The aim of our study is to assess the changes in CALR and CD47 levels during treatment of MDS and MPN with azacytidine (AZA) or ruxolitinib (RUXO), in a series of model cell systems.
Methods: CALR and CD47 gene and protein expression was measured in MDS cell line models (MOLM-13 and SKM-1), MPN cell line models (HEL-92 and GDM-1) and in an intermediate MDS/MPN cell line (K562) before and after treatment with AZA and RUXO. Drug titrations were completed, resulting in dosing regimens of 0.05μM/ml for both AZA and RUXO, with re-drugging occurring at 24 hours. Cells were then harvested, cDNA was synthesized for use in qPCR and protein levels determined by Western blot analysis.
Results: When treated with AZA, MDS cell models showed a 7-10 fold increase in CALR expression and 4-6 fold increase in CD47 expression. In contrast, the MDS/MPN intermediate cell model (K562) showed a 4.5 fold increase in CALR but only a 0.5 fold increase in CD47 expression. In the MPN model HEL-92, a 9 fold CALR increase and 5 fold CD47 increase was seen, whereas in the other MPN model (GDM-1 cells) expression was more evenly matched between CALR and CD47 (5.3 and 4.8 fold increases, respectively). After treatment with RUXO, MPN models showed a 9.5-16 fold increase in CALR expression and a 6-9 fold increase in CD47, which would be expected as RUXO is used to treat MPN in humans. When the MDS/MPN cell model or pure MDS models were treated with RUXO, the ratio of CALR/CD47 decreased substantially (with CALR expression only increased 2.4-3.7 fold compared to CD47 increasing 4.6-6.9 fold) showing resistance to treatment and a significant anti-phagocytic response. Interestingly one of the MDS cell line models (MOLM-13) showed an unexpectedly good response to RUXO therapy with high CALR/CD47 ratio (8 fold *vs* 4.8 fold, respectively).
Summary/Conclusions: In line with results in solid tumours, we have shown that treatment for MDS and MPN leads to an up-regulation of CALR and, to a lesser extent, CD47 in cell lines models. The ratio of CALR/CD47 seems to correlate with specific treatment response, significantly increasing when given diseases models are treated with the appropriate drug. We postulate a role of CALR expression in leukaemia cell phagocytosis, with CD47 co-expression in synergy as a protective instinct within the cell to try and prevent apoptosis. Some models showed an excessive rise in CD47 expression and low expression of CALR. This indicates that the CD47 mediated anti-phagocytosis takes control and supresses the CALR expression, leading to cancer cell survival and ineffectiveness of treatment. Those results need to be validated in human samples at different stages of disease to allow a better understanding of treatment response and/or resistance to chemotherapy within these diseases.

GENETIC VARIANTS OF MSH3 AND BLM GENES MAY INFLUENCE MYELODYSPLASTIC SYNDROME SUSCEPTIBILITY AND PROGNOSIS

M.S. Melo[1], L. Balanco[1], A. Barbosa Ribeiro[1,2], A.C. Gonçalves[1,2], R. Alves[1,2], E. Cortesão[1,2,3], L. Ribeiro[3], L. Mota-Vieira[4], A.B. Sarmento-Ribeiro[1,2,3,*]
[1]Applied Molecular Biology and University Clinic of Hematology, [2]CIMAGO, Faculty of Medicine University of Coimbra, [3]Clinical Hematology Department, Centro Hospital e Universitário de Coimbra (CHUC), Coimbra, [4]Molecular Genetics and Pathology Unit, Hospital do Divino Espírito Santo de Ponta Delgada, EPER, Ponta Delgada - Azores, Portugal

Background: Myelodysplastic syndrome (MDS) is a heterogeneous group of hematopoietic stem cell disorders, characterized by peripheral cytopenias, ineffective hematopoiesis and frequent transformation into acute myeloid leukemia (AML). Several mechanisms are involved in disease development and progression as a consequence of stepwise accumulation of DNA mutations, which infers a defect in DNA repair mechanisms. Mutations in DNA repair genes of the nucleotide excision repair (NER) group, and affecting the mismatch repair (MMR), and DNA crosslink repair genes, among others, are the cause of inherited cancer syndromes. On the other hand, genetic variants in genes involved in these mechanisms have been identified for their potential role in cancer susceptibility. However, in MDS, the relevance of these variants remains to be fully established and correlated with prognosis.
Aims: In the present study we investigate the influence of polymorphisms in DNA repair genes (*XRCC5, RMI1, RAD52, XRCC3, BLM, TOP3A, OGG1, LIG1, ERCC2*, and *MSH3*) as risk factor for MDS development as well as prognostic factors of acute leukemia transformation.
Methods: We performed a hospital-based case control-study to investigate the association of DNA repair genes with MDS susceptibility and prognosis in a group of Portuguese patients. To that end, we genotyped by TaqMan real-time PCR 10 SNPs (one per gene: *XRCC5, RMI1, RAD52, XRCC3, BLM, TOP3A, OGG1, LIG1, ERCC2*, and *MSH3*) in 60 MDS patients and 120 age-sex matched controls. Frequencies of alleles, genotypes, and genotypic profiles were estimated and compared between patients and controls. The role of these genes in MDS susceptibility was studied by logistic regression analysis. The influence in MDS prognosis was evaluated by estimating, through Kaplan Meier analysis, the rate of MDS transformation into AML and the overall survival.
Results: There was no significant difference in frequencies of *XRCC5, RMI1, RAD52, XRCC3, BLM, TOP3A, OGG1, LIG1* and *ERCC2* variants between patients and controls. In contrary, we found that heterozygous individuals for MSH3 c.2655+5137C>G had an increased susceptibility to MDS development (OR=6.882, 95% CI 1.789-26.479, p <0.003), being the increased risk attributed to G allele (OR=6.405, 95% CI 1.552 30.469, p <0.003). In addition, MDS patients homozygous for BLM c.-4-889A>C showed higher rate of MDS transformation into AML (HR=7.646, 95% CI 1.362 24467, p <0.023).
Summary/Conclusions: The present study suggests that MSH3 c.2655+5137C>G variant influences MDS susceptibility, and BLM c.-4-889A>C variant may be implicated in the propensity to AML transformation observed in MDS patients. Thus, these gene variants could be used as a risk and prognostic biomarkers for MDS, if these associations were replicated in a larger case-control study and/or with other populations.

PB1912

LOW RPS14 EXPRESSION IN MDS PATIENTS WITHOUT 5Q- ABERRATION SEEMS NOT TO BE RELATED WITH GENOMIC ALTERATIONS IN 5Q REGION

M. Linares[1,*], K. Quiroz[1], Y. Ruiz-Heredia[1], I. Rapado[1], T. Cedena[1], R. Ayala[1], J. Martínez-López[1]
[1]Servicio de Hematologia, Hospital Universitario 12 de octubre, Madrid, Spain

Background: Heterozygous deletion of RPS14 occurs in isolated interstitial deletion of chromosome 5q in patients with myelodysplastic syndrome (MDS). 5q- MDS has been linked to impaired erythropoiesis and it is characterized by a constant macrocytic anemia and normal or high platelet counts associated with hypolobulated megakaryocytes. Previous studies have detected reduced RPS14 expression in more than 50% of non-5q-patients. Recently, the pivotal role of RPS14 in human erythropoiesis during 5q- MDS pathology has been demonstrated: RPS14 haploinsuficiency produces the activation of p53 and its target p21 in erythroid cells, resulting in cell cycle arrest and apoptosis. Based on these results, non-5q- patients expressing low levels of RPS14 will be potentially beneficed by lenalidomide therapy. In this work, we explore the origin of the altered RPS14 expression in non-5q- patients and its potential link with 5q- pathology.
Aims: The objective of this work was to explore the origin of RPS14 low expression in non-5q- MDS patients and its link with 5q- pathology. In order to do this, we analysed potential mutations in RPS14 gene. We also studied expression changes in other key genes involved in the development of the 5q- disease, including the tumour suppressor gene SPARC and the putative tumour suppressor gene CSNK1A1, contained in the commonly deleted region. Moreover, other 32 genes related with MDS disorders were evaluated in relation with RPS14 levels. Finally, in order to establish if this group of patients could be beneficed by lenalidomide therapy, p21 expression levels were also analysed.
Methods: DNA and RNA were extracted from the bone marrow of 89 non-5q- MDS patients. Ten controls and nine 5q- MDS patients were used as negative and positive controls, respectively. RPS14, SPARC, CSNK1A1 and p21 mRNA levels were analysed by real time PCR using Taqman probes in a 7500 RT PCR System. β-glucuronidase gene was used as endogenous reference to normalize data. Samples were classified by RPS14 expression levels and differences in SPARC, CSNK1A1 and p21 expression mean values between the two groups were analysed using the Mann-Whitney U test. RPS14 and 32 genes related with MDS were analysed using Ion Proton sequencing.
Results: Non-5q- patients expressing low levels of RPS14 presented higher survival probability in the IPSS lower risk group. This data, in addition with a tendency for increased p21 expression, suggests that this group could be beneficed by lenalidomide therapy. Nevertheless, we did not observe a significant decrease in SPARC and CSNK1A1 expression in patients with low levels of RPS14, discarding alterations in the adjacent genes commonly deleted in 5q- MDS patients. In addition, the majority of patients analysed did not present any mutation in RPS14 gene. Only two MDS patients showed mutations upstream, downstream or within intronic regions of the gene. Then, the origin of RPS14 decreased expression seems not to be related with genomic alterations in 5q region. On the other hand, mutations in FLT3, U2AF1, DNM3A and CBL were frequently observed in this group of patients.
Summary/Conclusions: Although the important role of RPS14 in MDS pathol-

ogy has been recently demonstrated, the origin of RPS14 downregulation in about 50% non-5q- patients remains unknown. Our results suggest that the origin of RPS14 decreased expression is not related with genomic alterations in 5q region. Further studies are necessaries in order to establish a link with 5q- pathology and demonstrate the potential use of lenalidomide in this group of patients.

PB1913

INTEREST OF THE XN-10® ANALYZER TO SCREEN FOR MYELODYSPLASTIC SYNDROMES ON COMPLETE BLOOD COUNTS

R. Boutault[1], P. Peterlin[2], M. Boubaya[3], S. Tremblais[1], M. De Oliveira[1], Y. Le Bris[1], C. Godon[1], O. Theisen[1], M.C. Béné[1], M. Eveillard[1,*]
[1]Hematology Laboratory, [2]Hematology clinic, Nantes University Hospital, Nantes, [3]Clinical research, Avicennes University Hospital, Avicennes, France

Background: A prospective study was performed over one year in order to investigate whether suspected myelodysplastic syndromes (MDS) could be detected on a complete blood counts (CBC), the fastest laboratory investigation, performed on the recently developed XN-10® (Sysmex, Kobe, Japan).
Aims: The primary end point was to discriminate MDS patients from normal samples and the secondary end-point was to to distinguish MDS with excess blasts (MDS-EB), MDS with multilineage dysplasia (MDS-MLD), MDS with single lineage dysplasia (MDS-SLD) and MDS with ring sideroblasts and single lineage dysplasia (MDS-RS-SLD) within the MDS group and by comparison with controls as described by the WHO 2016 classification.
Methods: One hundred and thirteen patients were enrolled in the study, for whom a diagnosis of MDS was concluded based on CBC, bone marrow smears examination and karyotype. All patients were free of treatment, including transfusions, at inclusion. They were 63 men and 50 women with a median age of 82 years (range 36-96 yo). CBC were performed on a Sysmex analyzer XN-10®, including classical parameters (hemoglobin level, Mean Corpuscular Volume (MCV), reticulocytes, platelets, neutrophils and extra-parameters *i.e.* platelets by fluorescene (PLT-F), immature platelets fraction (IPF%), immature reticulocytes fraction (IRF%) and the neutrophils median position on the three axes as well as their dispersion (Neut-WX). For comparison with normal values, results from 707 healthy subjects over 50 years old, for whom CBC were performed on the same analyzer and generated no flag, were used. All had parameters within the normal range according to age. According to the WHO, 37 patients in the cohort had MDS-EB, 35 MDS-MDL (among whom 7 had ring sideroblasts [RS]), 26 MDS-SLD- RS, 12 MDS-SLD without RS and 3 MDS with isolated del(5q). Sixty-two patients had a normal karyotype, 24 displayed anomalies classically reported in MDS, and 8 had complex karyotypes. Among the latter, 7 were associated with MDS-EB.
Results: Both classical and extra parameters indeed showed significant differences between the subgroups tested. Among the whole group of MDS patients, a number of parameters of all lineages were statistically different from the healthy cohort. The median level of hemoglobin was 9,92±1,96 g/dL (p<0,0001), the median MCV (99,24±10,56 fL p<0,0001), reticulocyte counts 44,3x10^9/L (range 8-165,9; p=0,041) and IRF% 16,7% (range 2,4-50,9; p<0,0001). The median platelet count was 194 ±128x10^9/L (p<0,0001) and the median IPF% 8,8% (1,2-42; p<0,0001). Among leukocyte parameters, the MDS median neutrophil count was significantly lower at 3,08±2,58x10^9/L (p<0,001) while Neut-WX was significantly higher (387±71;p<0,0001). The latter, allowed to predict a diagnosis of MDS with 73% sensitivity and 97% specificity. For patients over 50 years old, 4 parameters (Neut, Neut-WX, hemoglobin level and MCV) in a score allow to diagnose MDS with 92% sensitivity and 81% specificity . When considering MDS subgroups, although each of them was significantly different from controls for hemoglobin levels, MCV and IRF% and (p<0,0001), they could not be discriminated by these parameters. In the subgroup of MDS with single lineage dysplasia and ring sideroblasts, platelet counts were similar to those of controls, yet significantly higher than for MD-EB or MDS-MLD (p=0,004 and p=0,029 respectively). Moreover, neutrophils counts were significantly lower in MDS-DML or MDS-EB than in MDS-SLD-RS.
Summary/Conclusions: This study demonstrates that a simple CBC allows to screen for MDS using a multiparameter score including Neut-WX. Blood smear examination should be performed in this situation even if the XN-10® analyzer does not raise any alarm, especially in unknown patients older than 50.

PB1914

PROGRESSION SCORE FOR ACUTE LEUKEMIA – A NEW PROGNOSTIC SCORE IN MDS?

E. Cortesão[1,2,*], A.C. Gonçalves[1], A.R. Tenreiro[2], A. Ribeiro[1,2], C. Geraldes[1,2], N. Costa e Silva[3,4], L. Ribeiro[2], J. Nascimento Costa[5], A.B. Sarmento-Ribeiro[1,2]
[1]Applied molecular biology and clinic university of hematology, Faculty of Medicine of University of Coimbra, [2]Hematology, [3]Clinical Pathology, Centro Hospitalar e Universitário de Coimbra (CHUC), Portugal, [4]Histology and Embryology, [5]Clinic university of oncology, Faculty of Medicine of University of Coimbra, Coimbra, Portugal

Background: Since 1997, the *International Prognostic Scoring System* (IPSS) has been the standard for stratifying patients with Myelodysplastic Syndrome (MDS). Although other models were proposed to improve this stratification, some issues remain, notably the identification of low-risk patients with poor prognosis who may benefit from earlier and/or aggressive therapy.
Aims: The aim of our work was the conception of a new prognostic score in MDS, based in the cellular and molecular disease characterization.
Methods: Our sample consisted of 102 patients diagnosed with MDS de novo. The median age was 74 years (22-89), with a 0.8 Male to Female ratio. The subtypes, according to the World Health Organization 2008, were Refractory Cytopenia with Multilineage Dysplasia (RCMD) (n=52), Refractory Cytopenia with Unilineage Dysplasia (RCUD) (n=12), Refractory Anemia with Excess Blasts type 1(RAEB-1) (n=8), RAEB-2 (n=8), Refractory Anemia with Ringed Sideroblasts (n=6), 5q- syndrome (n=4) and Chronic Myelomonocytic Leukemia (n=12). The IPSS based stratification was: low (n=37), intermediate-1 (n=39), intermediate-2 (n=10) and high (n=1). Several variables were analyzed: hematological (leukocytes, neutrophils, hemoglobin, platelets, blasts and ring sideroblasts), biochemical (erythropoietin, β2-microglobulin, folic acid, vitamin B12, ferritin, LDH), imunophenotypic (hematopoietic stem cell characterization by flow cytometry, FC, using the markers, CD34 / CD117 / CD123 / GlicoP / IL-6 / TNFa) and molecular characteristics (methylation profile of genes *p15*, *p16*, *DAPK*, *R1*, *R2*, *R3* and *R4* performed by PCR-MS, and evaluation of expression levels of regulatory molecules of apoptosis BCL-2, BAX, TRAIL, R1, R2, R3, R4, FAS, Survivin, Caspase 3, Cit C, GlycoP and p53, by FC).
Results: In the 60-month follow-up, 11 patients progressed to Acute Myeloblastic Leukemia (AML), 7 with RAEB-2, 2 with RCMD, 1 patient with RAEB-1 and another with CMML. These patients had a higher% of ring sideroblasts and blasts; higher scores on IPSS, IPSS-R and WPSS; lower platelet counts, higher erythropoietin levels and greater expression of CD34 / CD117 / IL-6. Assigning a value (+1) to each altered variable a new prognostic score was obtained, which we named Progression Score for Acute Leukemia. We observed that patients belonging to subtypes with the highest scores were those that progressed to AML, namely RAEB-1, RAEB-2 and RCMD.
Summary/Conclusions: In conclusion, we believe that this score may contribute to evaluate the risk of progression to AML, by reflecting the heterogeneity of MDS and its multifactorial etiology. The coexistence of many altered variables not only contributes to the etiopathogenesis of MDS but also allows the assessment of potential leukemic transformation.

PB1915

CORRELATION OF PATIENT PROGNOSIS WITH PU.1 AND JDP2 PROVIDES POTENTIAL NOVEL PROGNOSTIC/DIAGNOSTIC MARKERS IN MDS

R. Simpson[1,*], A. Goddard[1], J. Lally[1], M. Simmonds[1], C. Rinaldi[2]
[1]University of Lincoln , [2]University of Lincoln and United Lincolnshire Hospital Trust, lincoln, United Kingdom

Background: PU.1 is a key transcription factor in haematopoiesis that plays important roles in various haematological malignancies. Previously, significant down-regulation of PU.1 has been reported in high risk myelodysplastic syndrome (MDS) and acute myelogenous leukemia (AML) patients.
Aims: To clarify PU.1 molecular function we investigated the gene expression of PU.1 and JDP2 (c-Jun dimerization protein-2), a member of the activating protein-1 family located downstream of PU.1, in bone marrow from 12 MDS patients stratified according to IPSS-R score (6-low, 3-intermediate, 3-high risk), 1 AML patient and 10 normal controls.
Methods: Samples were enriched for the mononuclear fraction by Ficoll separation. Total RNA was extracted and analysed by Real Time PCR for PU.1 and JDP2 expression relative to the housekeeping gene GAPDHusing the 2-ΔΔCT method. Western blot has been perfomed using anti-PU.1 and anti-JDP2 (Abcam)according to manifacture instructions.
Results: We revealed both PU.1 and JDP2 are down regulated in MDS. In addition, our data suggests that PU.1 and JDP2 expression inversely correlates with disease, with expression of these genes consistently reducing according to IPSS-R groups. Furthermore, a positive correlation of PU.1 and JDP2expression <R=O.9333, s=0.0004 >, provides additional evidence that suppression of JDP2 by PU.1 could contribute to the pathogenesis of AML. Notably, PU.1 and JDP2 do not correlate to the same extent in normal HSCs, indicating that cofactors are required for PU.1 to exert its JDP2-regulating function and that such cofactors are not present under normal conditions. To confirm that JDP2 suppression is a direct result of reduced PU.1 we performed PU.1-knockdown in K562 cells stably expressing PU.1 short interfering RNAs *versus* control cells. These analyses reveal only a partial reduction in JDP2 expression when analysed by RT-PCR and Western blot, suggesting a more complex regulatory mechanism. Additionally, both PU.1 and JDP2 expression was recovered by treatment with azacitidine, which is routinely used to treat MDS, suggesting an involvement in treatment response.
Summary/Conclusions: PU.1 and JDP2 expression correlates with patients prognosis highlighting a potential role as new diagnostic and prognostic markers in MDS.

PB1916

DECREASED EXPRESSION OF DECORIN, A WNT-PATHWAY RELATED PROTEIN, IN MESENCHYMAL STEM CELLS OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES

K. Pavlaki[1,*], A. Batsali[1], M. Lazaris[1], S. Mastrodemou[1], M. Ximeri[1], C. Pontikoglou[1], H. Papadaki[1]
[1]Department of Haematology, University of Crete School of Medicine, Heraklion, Greece

Background: Myelodysplastic syndromes (MDS) are clonal disorders of the haematopoietic stem cells (HSCs) characterized by inefficient bone marrow (BM) haemopoiesis and increased risk for leukaemic evolution. Ineffective BM haemopoiesis in MDS has also been linked with an abnormal microenvironment that may sustain or even induce the aberrations within the HSC compartment. We have previously shown that the stroma progenitor cells, namely the mesenchymal stem cells (MSC), in MDS patients display impaired clonogenic and proliferative potential, reduced haemopoiesis supportive capacity and down-regulation of the canonical Wnt-signaling pathway.
Aims: Decorin, a small leucine-rich proteoglycan, and galectin-3, a member of b-galactosidase specific lectin family, are components of the extracellular matrix of the BM microenvironment. Both proteins have been implicated in the canonical Wnt-pathway participating therefore in cell growth and proliferation. The aim of the study is to assess the expression of decorin and galectin-3 in MSCs of MDS patients, evaluating their implication in the abnormal Wnt-signaling previously reported in MDS.
Methods: BM MSCs were isolated from 12 patients with lower risk MDS aged 51 to 75 years (median 67.5 years) and 12 haematologically healthy subjects aged 50 to 73 years (median 63.3 years), after informed consent. The study has been approved by the Ethics Committee of the University Hospital of Heraklion. BM MSCs were characterized according to international system for human cytogenetic nomenclature (ISCN) criteria, expanded and re-seeded for two passages (P). Total RNA was extracted from culture-expanded P2 MSCs and amplified by real-time PCR for the evaluation of decorin and galectin-3. Relative gene expression was calculated by the ΔCt method.
Results: A statistically significant decreased expression of decorin was identified in MSC of MDS patients (mean 1.338, SD 0.84) compared to the healthy individuals (mean 1.830, SD 0.71). ($P<0.05$). Galectin-3 expression was also decreased in MDS patients (mean 0.6758, SD 0.50) compared to controls (0.9395, SD 0.50), although not at a statistically significant levels.
Summary/Conclusions: MSCs from MDS patients display statistically significant decreased expression of decorin and a tendency towards decreased expression of galectin-3 in BM MSCs compared to healthy individuals. These preliminary data indicate that extracellular matrix proteins may have a role in the disturbed Wnt-pathway signaling and abnormal MSC function in MDS patients. The underlying mechanisms are currently under investigation.

CLINICAL FEATURES, CYTOGENETIC STUDY AND OUTCOME OF ADULT MYELODYSPLASTIC SYNDROMES: REVIEW OF 101 CASES, A SINGLE CENTER EXPERIENCE IN ALGERIA

S. Taoussi[1,*], Y. Bouchakor-Moussa[1], M. Abad[1]
[1]Hematology, EHS ELCC CAC, Blida, Algeria

Background: Myelodysplastic syndromes (MDS) are heterogeneous disorders defined as clonal diseases involving hematopoietic stem cells and even characterized by cytopenias, with a high risk of leukemic transformation. Morphological analysis of peripheral blood (PB) and marrow aspirates or bone marrow biopsies is the first step that ensures a diagnosis of MDS. Cytogenetic studies are important means of defining different prognostic groups and even of showing how patients are eligible for this or that treatment. We conducted the first study including conventional karyotyping and fluorescent *in situ* hybridization (FISH) for MDS in our country.
Aims: Our study was aimed to evaluate outcome of MDS regarding IPSS and IPSS-R classification in an emerging country.
Methods: Between January 2012 to December 2016, 101 patients with MDS were consecutively diagnosed. Frequent genetic abnormalities in MDS were screened by R-banding karyotype and metaphasic and interphasic FISH using a panel including six probes (5q-,7q-,20q-, del(17p13), MLL, Inv(3) t(3;3). Patients were stratified into risk groups according to IPSS and IPSS-R scores; survival probabilities were estimated using the Kaplan-Meier method.
Results: Among these 101 pts, 58 were male with a sex ratio=1, 35; range in age is from 18 years to 94 years with a median of 61, 6 years. Median hemoglobin value was 80 g/L (29-150), more than 60% of patients had severe anemia mainly in the low risk group; the median absolute neutrophil count was 3 G/L (0,060-13, 5), and the median platelet count was 144 G/L (5-659). Median bone marrow blast value was 4% (0-18). Cases were classed by cytomorphology FAB as RA (N=45), REAB (n=34), RARS (n=16), other (n=6). Classification by WHO 2008 included CRDU (n= 31 of which RA : 18, RT : 10, RN : 3), CRDM (n= 16), RAEB-1 (n=22), RAEB-2 (n= 13), RARS (n= 15), Isolated 5q- (n=4). Among 101 patients, cytogenetic abnormalities by R banding karyotype (n= 84) and FISH (n=101) were found in 41 cases (41%) distributed as single anomaly (n= 19) , double anomaly (n=5) and complex (n=17). The main cytogenetic abnormalities seen were isolated 5q deletion (n=4), isolated 7q deletion (n=2), isolated 20q deletion (n= 6), isolated trisomy 8 (n=2), 17p13 deletion (n=6), - Y (n=1), complex aberrations ≥3 (n=6) , complex aberrations ≥5 (n=6), complex aberrations ≥7 (n=5), others (n=3). IPSS was assessed in 84 patients: 27% (low risk), 44% (intermediate 1) , 24% (intermediate 2), 5% (high risk). IPSS-R was assessed in 84 patients (18% very low risk, 30% low risk, 22,5% intermediate, 15,5% High risk, 14% very High risk). Leukemic transformation into AML occurred in 33% of patients in a median time of 12 months. According to IPSS, the median OS time survival is not reached for low risk group, 41 months (m) for Intermediate 1 risk, 11 m for Intermediate 2 risk, and 4 m for High risk. According to IPSS-R, the median OS time survival is not reached for Very low risk, 43 m for low risk, 24 m for Intermediate risk, 18 m for High risk and 4 m for very high risk.
Summary/Conclusions: Our results are in agreement with those previously published regarding demographic features, distribution of recurring cytogenetic abnormalities and prediction of survival. Myelodysplasias are among the most difficult haematological diseases to treat. Treatment of low risk and high risk myelodysplasia are completely different, the last group carrying a great risk of leukemic transformation. For all these reasons, application of the new tools to classify MDS is of an major importance. This is especially true in emerging countries where few therapeutic means are available, hence the need to predict the prognosis of these diseases in order to better target treatments. To the best of our knowledge, it is the first study conducted in our country.

Myelodysplastic syndromes - Clinical

PB1918

CLINICAL EVOLUTION OF ACUTE MYELOID LEUKEMIA WITH MYELODYSPLASIA-RELATED CHANGES

G. Pinto[1,*], P. Herrera[1]
[1]Hematology, HOSPITAL RAMON Y CAJAL, Madrid, Spain

Background: Acute myeloid leukemia (AML) with myelodysplasia-related changes (MRC) is usually classified associated to worse clinical course and poor prognosis compared other AML subtypes. Differences between treatment modalities according to age, and the response to treatment, would help to provide specific anti-AML treatment in this difficult scenario.
Aims: The objetive of this study is analyze the clinical features and course of patients with AML with MRC, in order to evaluate the impact of different therapeutic regimens in this subgroup.
Methods: We report an unicentric retrospective study of 76 patients with AML with MRC, over the past ten years in a single institution in Spain. We analyzed the overall survival (OS) among the subgroup of patients with over or under 65 years, and the different types of treatment that has been offered.
Results: Median age was 69 years with a male predominance, and 66% was preceded by a known myelodysplastic syndrome with a median interval of 18 months to progress to AML. The more frequent genetic abnormalities in descending order were trisomies, del(5q), and del(7q)/-7. The patients aged >65 and <65 were 70% and 30%, respectively. The patients aged >65 received DNA hypomethylating agents (40%), anthracycline-cytarabine combinations (9%), low-dose cytarabine or hydroxyurea (17%), and supportive measures (34%). The patients aged <65 received induction chemotherapy with anthracycline-cytarabine combinations so as to continue with post-consolidation management with allogenic transplantation, but the 44% died over the induction chemotherapy (OS: 2.2 months). The OS in patients aged <65 was 20,2 months in chemotherapy plus allogenic transplantation. The OS in patients aged >65 was 10,3 months in the group of anthracycline-araC combinations, 3,81 months in the DNA hypomethylating agents group, 2,8 months in the low-dose of AraC/hydroxiurea, and 0,5 months in supportive measures group (Figure 1).

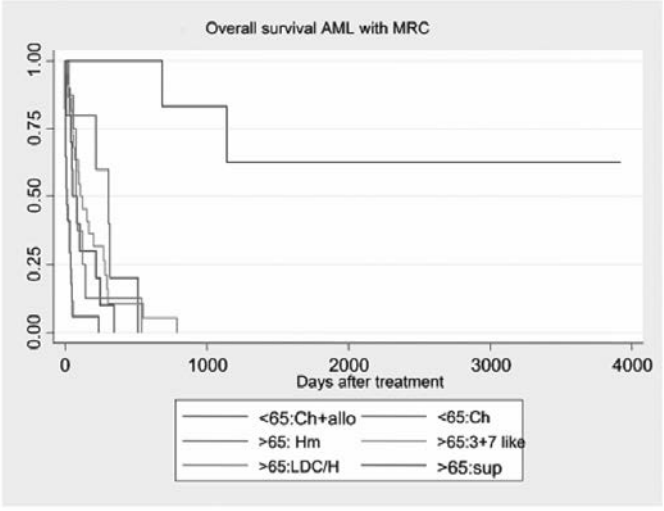

Figure 1.

Summary/Conclusions: The AML with MRC patients is a group with difficult treatment decisions and poor prognosis, in whom only the chemotherapy plus allogenic transplantation treatment manage long-term survival. In patients aged >65, there is not a significant difference among groups, although the chemotherapy with anthracycline-cytarabine seems to reach a better OS *versus* other available treatments.

PB1919

SAFETY, EFFICACY, AND PHARMACOKINETICS OF INTRAVENOUS RIGOSERTIB IN JAPANESE PATIENTS WITH RECURRENT/RELAPSED OR REFRACTORY MYELODYSPLASTIC SYNDROMES: A MULTICENTER, OPEN-LABEL, PHASE I STUDY

M. Ogura[1,2,*], Y. Kobayashi[3], S. Kubonishi[4,5], M. Hidaka[6], T. Uchida[2], Y. Takamatsu[7]
[1]Department of Hematology, Tokai Central Hospital, Kakamigahara, [2]Department of Hematology and Oncology, Nagoya Daini Red Cross Hospital, Nagoya, [3]Department of Hematology, National Cancer Center Hospital, Tokyo, [4]Department of Hematology, National Hospital Organization Okayama Medical Center, Okayama, [5]Department of Hematology, Red Cross Society Himeji Hospital, Himeji, [6]Department of Hematology, National Hospital Organization Kumamoto Medical Center, Kumamoto, [7]Division of Medical Oncology, Hematology, and Infectious Diseases, Fukuoka University Hospital, Fukuoka, Japan

Background: Rigosertib, a novel phosphoinositide 3/polo-like kinase pathway inhibitor, selectively induces the apoptosis of cancer cells and is safe and well tolerated in pts with recurrent/relapsed or refractory MDS.
Aims: We conducted a multicenter, open-label, Phase I study of intravenous rigosertib to evaluate its safety, efficacy, and pharmacokinetics and to determine the recommended dose (RD) for Japanese pts.
Methods: The key eligibility criteria were as follows: recurrent/relapsed or refractory MDS; age: 20 or older; FAB classification (RA, RARS, RAEB, RAEB-t, and CMML), excepting patients at IPSS low- or Int-1 risk with respect to RA; ECOG PS of 0 to 2; no major organ dysfunction; and written informed consent. Rigosertib (1,200 and 1,800 mg daily) was administered intravenously for 72 h, followed by 11-day monitoring in one 14-day cycle. The primary endpoint was dose-limiting toxicity (DLT). The secondary endpoints were 1) safety as assessed with adverse events (AEs) and laboratory results; 2) efficacy as assessed with the International Working Group 2006 criteria; and 3) pharmacokinetics.
Results: Between June 2012 and February 2015, 7 male and 2 female pts (median age: 70; range: 63-84) were enrolled, and 3 and 6 pts were eventually assigned to the 1,200 and 1,800 mg arms, respectively. According to the FAB classification, 6, 2, and 1 pts were categorized to RAEB, RAEB-t, and RA, respectively. There were 3 pts each in the IPSS Int-1, Int-2, and high-risk groups, with 1 and 2 pts in each risk group in the 1,200 and 1,800 mg arms, respectively. The median numbers of delivered cycles in the 1,200 and 1,800 mg arms were 4 (2 to 4) and 2 (1 to 8), respectively. DLT occurred not in the 1,200 mg arm but in the 1,800 mg arm: 5 episodes of ≥grade 3 non-hematologic toxicities in 2 pts. One pt developed 2 episodes of sepsis and meningitis, and the other 3 episodes of hypochloremia, pustular rash, and hyponatremia. Thus, 2 among 6 pts in the 1,800 mg arm developed DLT, which led us to conclude that 1,800 mg/day is the RD for Japanese pts. No deaths occurred during the study period. However, 5 pts died during follow-up, 4 of whom died from primary disease progression. Furthermore, 1 pt died of grade 5 bacterial pneumonitis that was rated to "Unrelated". In the 1,200 mg arm, 2 cases each of grade 3/4 thrombocytopenia, grade 4 neutropenia, and grade 3/4 leukopenia, as well as 1 case of grade 3 lymphopenia developed. In the 1,800 mg arm, 3 cases of grade 3/4 leukopenia, 2 cases each of grade 3 CD4 lymphopenia, grade 4 thrombocytopenia, and grade 3/4 neutropenia, as well as 1 case each of grade 4 lymphopenia, increased C-reactive protein, erythropenia, and hypochloremia developed. Three cases of SAEs, including grade 4 meningitis, grade 4 sepsis, and grade 3 catheter-related infection, developed in the 1,800 mg arm. Stable disease was obtained in 2 pts in the 1,800 mg arm. Hematological remission, hematological improvement, and cytogenetic response were not obtained in the two arms. The C_{max} values in the 1,200 and 1,800 mg arms were 5.99±1.50 and 6.74±2.39 μg/mL, respectively. The $AUC_{0-\infty}$ values were 314.6±142.7 and 324.8±83.9 μg × hr/mL, respectively.
Summary/Conclusions: This Phase I study showed that intravenous rigosertib (1,800 mg daily) for consecutive 72 h was well tolerated, indicating that this is the RD for Japanese pts with MDS similar to a Phase III study in the U.S. Based on these clinical outcomes, Japanese pts with MDS are participating in a global randomized Phase III study to compare rigosertib with physicians' choice of treatment.

PB1920

IRON CHELATION THERAPY IMPROVES HAEMATOLOGICAL RESPONSE IN HIGH-RISK MYELODYSPLASTIC PATIENTS TREATED WITH AZACITIDINE

S. Improta[1], M.R. Villa[1,*], P. Della Cioppa[1], A. Lucania[1], M. Esposito[1], G. Nitrato Izzo[1], A. Gagliardi[1], L. Mastrullo[1]
[1]UOC Ematologia PO Ascalesi ASL Napoli1 Centro, Naples, Italy

Background: The goals of treating older patients with Myelodysplastic Syndrome (MDS) are different than for younger patients. Few elderly patients are able to pursue an allogeneic stem cell transplant. Azacitidine (AZA) improves long-term outcomes of higher-risk MDS patients and is now the reference front-line therapy of higher-risk MDS not eligible for allogeneic stem cell transplant. Anaemia is the most common symptom of MDS and most patients become transfusion-dependent with the risk of iron overload. Deferasirox is an orally available iron chelator administered once-daily in transfusion-dependent patients with various chronic anaemias. Its efficacy has been established in controlled clinical trials.
Aims: We report our experience on using the azacitidine in patients with high-risk MDS, evaluating the efficacy and safety. Concomitant treatment with deferasirox was performed in a routine clinical setting following Consensus Guidelines on Iron Chelation Therapy.
Methods: In our Institution from October 2009 to January 2017 we have

treated 32 elderly patients (19 male and 13 female, median age 76 years, r. 71-88) affected by HIGH-RISK MDS (IPSS INT-2/HIGH). Patients received subcutaneous azacitidine at 75mg/m(2) daily for 7 days every 4 weeks. All patients completed at least 6 cycles of therapy. 12/30 (40%) patients underwent more than 8 cycles of therapy. 18/30 patients underwent as well iron chelation therapy with deferasirox receiving a starting dosage of 10 mg/kg/day, subsequently titrated according to serum ferritin (SF) measured monthly.
Results: Complete response (CR), partial response (PR), and hematologic improvement (HI) were observed in 2 (7%), 5 (17%), and 12 (40%) patients, respectively. The median number of cycles to clinical response was 4 (range 4-8). The 2-year rate of acute myeloid leukemia-free survival was 48%. Five serious adverse events occurred in five patients with one fatal outcome. 16 out of 18 patients who showed any hematologic response (CR+PR+HI) meeting International Working Group 2006 criteria had also performed deferasirox therapy. No increased toxicity was noted when deferasirox was used concomitantly with azacitidine.
Summary/Conclusions: Our results confirm the effectiveness of the therapy with azacitidine in HIGH-RISK MDS elderly patients with acceptable toxicity profile. Peripheral cytopenias were the most commonly occurring adverse event, with gastrointestinal adverse events and injection-site reactions among the most commonly occurring non-haematological adverse events. In conclusion, azacitidine is an important agent for use in the treatment of elderly patients with MDS. Furthermore concurrent use of deferasirox in patients with iron overload seems to significantly improve the hematologic response by reducing transfusion requirement.

PB1921

EXPLORING THE RISK OF RED CELL ALLOIMMUNIZATION IN MYELODYSPLASTIC SYNDROMES. TO WHAT EXTEND COULD CYTOGENETIC ANALYSIS AT DIAGNOSIS PREDICT THIS RISK?
I. Koutsavlis[1,*], J. Falconer[2], J. Fleming[3], H. Roddie[1]
[1]Haematology, [2]Blood Transfusion Service, [3]Cytogenetics Service, NHS LOTHIAN, Edinburgh, United Kingdom

Background: Red cell alloimmunization poses a huge burden for the blood transfusion services as it may be associated with crossmatching difficulties, haemolytic transfusion reactions and potentially severe clinical consequences for the transfused patient. Collectively, alloimmunization appears to be higher in patients with myelodysplasia (MDS) and chronic myelomonocytic leukaemia (CMML) with a rate somewhat around 15%. Identification of patients at risk of developing alloantibodies would be of clinical significance as antigen negative red cells could be crossmatched in advance for use in clinical practice. Largely, studies have failed to predict this cohort of patients and little is known regarding identifiable risk factors.
Aims: To this end, we focused on exploring the cytogenetic profile from patients with MDS and CMML along with demographic characteristics as risk factors for alloimmunization.
Methods: A retrospective analysis was performed in 360 transfused patients with MDS (74.4%) and CMML (25.6%) registered in our local database between 1980 and 2016. Prognostic variables (age, sex, disease subtype) were assessed using a multivariate prediction model in SPSS statistical software. Cytogenetics at diagnosis were available in 228 of the above patients and univariate analysis was performed separately.
Results: The mean age at diagnosis was 73 years (range 20-95) with 58.3% male patients. Overall, 45 patients (12.5%) formed 76 antibodies [68 alloantibodies, 8 autoantibodies] with 42% of them developing more than 1 antibody. 5 additional patients developed autoantibodies without alloantibodies. Alloantibody specificities were as follows: E (22 cases), C (8), K (7), Cw/ Jka/ Kpa (5 cases each), Lua (4), e/ Fya (3 cases each), M (2), c/ D/ Chido/ Bga (1 case each). Collectively, alloantibodies against the Rh and Kell systems encountered in 69% of this cohort. 6 out of 8 patients with anti-C had also developed a second antibody. In a regression model, none of the following variables reached statistical significant level as predictors for immunization; age (p=0.59), sex (p=0.07), MDS WHO subtype (p=1.0). 228 patients had known cytogenetics at diagnosis. Normal profile (46, XY or 46, XX) was encountered in 58.8%. Similarly, univariate analysis of this cohort (normal *versus* abnormal cytogenetics) showed odds ratio 1.1 with no statistical significant point (p=0.64). Further subgroup analysis was performed to explore whether the risk was increased in patients with poor or very poor cytogenetics as per IPSS-R. Descriptive statistics showed; very good/ good risk cytogenetics 69.7%, intermediate 12.7% and poor/ very poor 17.5%. Logistic regression analysis revealed no association between cytogenetic groups and risk of alloimmunization (p=0.89, p=0.96 and p=0.84 respectively).
Summary/Conclusions: The rate of alloimmunization in our cohort of patients was 12.5%, slightly lower compared to published studies. The most common alloantibody found was anti-E. Prognostic variables included in analysis (age, sex, MDS type but also cytogenetic profile) are not significant predictors of alloimmunization and further studies are needed to investigate other possible risk factors. Prophylactic Rh and Kell antigen matched cells, when possible, would be a reasonable strategy until further knowledge is acquired.

PB1922

PROGNOSTIC MARKERS THAT PREDICT THE OUTCOME OF REDUCED INTENSITY CONDITIONING TRANSPLANT IN ADULT PATIENTS WITH MYELODYSPLASTIC SYNDROMES: A SINGLE CENTER EXPERIENCE
S. Elashwah[1,*], S. Shamaa[2], H. Kamel[3], M. Samra[4], E. Azmy[1]
[1]Clinical Hematology, [2]Medical Oncology, Mansoura University, Mansoura, [3]Clinical Hematology, [4]Medical Oncology, Cairo University, Cairo, Egypt

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of hematologic diseases, characterized by a clonal abnormality of hematopoietic stem cells. The incidence of MDS is age-dependent. The treatment approach is to categorize patients into lower or higher risk MDS and to select a suitable treatment accordingly. HCT offers potentially curative therapy for patients with MDS. A reduced intensity conditioning (RIC) regimen was used to reduce the toxicities associated with transplant procedure. The main concept of RIC relay upon adoptive immunotherapy especially in the low risk patients allowing the graft *versus* leukemia to occur.
Aims: This study aimed to investigate the outcome of allogeneic peripheral blood stem cell transplantation after reduced intensity conditioning regimen for adult patients with MDS, the effect of different prognostic factors on outcome and the effect of chronic GVHD according to IPSS risk.
Methods: A retrospectively study analyzed the fifty-one patients with MDS who underwent transplantation at the BMT unit at Nasser Institute during a period of 10 years, by the RIC regimen from HLA identical donor using peripheral blood stem cell. Outcomes analyzed the incidence of acute and chronic GVHD, disease free survival (DFS) & overall survival (OS).
Results: They were 31 males (60.8%) and 20 females (39.2%). Their ages ranged from 17 to 60 years, with mean age±SD of 34.5±10.1 years, including refractory cytopenia with multiple dysplasia (RCMD) in 14 patients (27.5%), MDS –U in 13 patients (25.5%), refractory anemia (RA) in 12 patients (23.5%), refractory anemia with excess blasts II (RAEB II) in 6 patients (11.8%) and MDS with hypocellular bone marrow in 4 patients (7.8%) and refractory anemia ring sideroblasts (RARS) in 2 patients (2%). According to IPSS classification, 11 patients (21.6%) were low risk, 28 patients (54.9%) were intermediate-I risk group, and 9 patients (17.5%) were intermediate-II & 3 patients (5%) were high risk group. The incidence of acute and chronic GVHD were 51.1% and 28.6% respectively. The 5- year estimate for overall survival of the whole group was 21.8%. In univariate analysis, covariates associated with a better OS were recipient age <40 years (p=0.02) and the presence of cGVHD (p=.002). On multivariate analysis the presence of cGVHD is significant predictor of survival (p=0.04). Also cGVHD significantly improve the OS for low and high risk MDS group (p= 0.02 and 0.03 respectively). While presence of acute GVHD, IPSS & interval between diagnosis and transplant weren't significantly affect OS (p>0.05). The 5- year estimate for DFS of the whole group was 28.6%. On multivariate analysis the presence of cGVHD significantly reduce relapse (p=0.029).
Summary/Conclusions: The presence of cGVHD significantly improved OS and reduced the risk of relapse in patients with MDS. We also found that the presence of cGVHD significantly improved OS especially in high-risk patients group, which suggests that the GVL effect may be beneficial in high-risk patients who do not receive intensive preparative regimens.

PB1923

MANAGEMENT OF MYELODYSPLASTIC SYNDROMES WITH ERYTHROPOIESIS STIMULATING AGENTS IN REAL-LIFE EXPERIENCE: AN UPDATE FROM RECAMDS
C. Cerchione[1,*], O. Vitagliano[1], R. Della Pepa[1], G. Cerciello[1], A.E. Pareto[1], M. Di Perna[1], I. Soriente[2], P. Danise[3], A.M. D'Arco[3], F. Alfinito[4], F. Pane[4]
[1]Hematology, Ematologia e trapianto/au federico ii, [2]Hematology, Ospedale Umberto I, Napoli, [3]Hematology, Ospedale Umberto I, Nocera Inferiore (SA), [4]Ematologia e trapianto/au federico ii, Napoli, Italy

Background: Erythropoiesis stimulating agents (ESAs) are the frontline treatment in low-risk anemic MDS patients and an employment of this therapy in the earlier stage of the disease can delay the need for RBC transfusion, hypothetically by slowing the disease course. It's matter of debate whether the clinical response is a result of proliferation and maturation of the dysplastic clone or stimulation of residual normal erythropoiesis by ESAs.
Aims: Macrocytosis is one of the cytological hallmarks of dyserithropoiesis in MDS: an analysis of the erythropoietic response to ESAs therapy in a cohort of anemic non trasfusion-dependent MDS patients, enrolled in a retrospective register, RECAMDS, subgroup of Italian register, was performed.
Methods: 183 patients, treated with standard-dose ESAs, have been retrospectively analyzed (Table 1). Data analysis was performed, according to IWG 2006 criteria, at the baseline, after 3 and 6 months of continuous treatment, with a subanalysis of the patients according to WHO and R-IPSS risk stratification. ESAs were started at mean Hb concentration of 9.31 g/dl, mean serum EPO concentration: 51 mU/L, after a mean time from diagnosis of 6 months (r.1-118).
Results: Overall response rate(ORR) was 83.6% (153/183), no difference among WHO and IPSS subgroups was found: 132/183 (72.1%) achieved response after 3 months of treatment, while other 21/183 (11.2%) after 6 months. 19 patients with stable disease (non-responders, according to IWG

criteria), in which treatment was continued, achieved response after 9 months. In the macrocytic-responders group 83.2% exhibits again macrocytosis after 3 months, while 16.8% become normocytic. In the normocytic-responders group 89.8% exhibits again normocytosis, while 10.2% become macrocytic: in these patients, after 3 months, there was a contemporary worsening in neutropenia and thrombocytopenia, with transfusion-dependence, regarded as first signs of progression of disease. Non-responders were 30/183 (16.3%): in the macrocytic non-responders group 89% exhibit again macrocytosis after 3 months, while 11% become normocytic; in the normocytic group 76% exhibits again macrocytosis, while 24% become normocytic.

Table 1.

MDS PATIENTS	183
M	89 (49%)
F	94 (51%)
ERYTHROPOIESIS	
BASELINE HB (mean, g/dL)	9.31 g/dL (r. 7.1-11.3)
BASELINE SERUM EPO (mean, mU/mL)	51 mU/mL (r.3-84)
OVERALL RESPONSE RATIO	
RESPONDERS	153/183 (83.6%)
RESPONDERS AT 3 MONTHS	132/183 (72.1%)
RESPONDERS AT 6 MONTHS	21/183 (11.4%)
RESPONDERS AT 9 MONTHS (NON RESPONDERS IN IWG 2006)	19/183 (10.3%)
NON RESPONDERS	30/183 (16.3%)

Summary/Conclusions: These preliminary data can suggest that, in the majority of MDS patients responsive to ESAs, the increase of Hb concentration occurs mainly stimulating erythroid production in MDS clones; in the minority of patients probably it happens recruiting residual polyclonal erythropoiesis. It is interesting to note that stimulating effects of ESAs last even when the expression of dysplasia progresses.

PB1924

CHARACTERIZATION OF MYELODYSPLASTIC SYNDROMES WITH TRANSFORMATION TO ACUTE LYMPHOBLASTIC LEUKAEMIA

F. Martins[1], J. Pouw-Schoumans[2], R. G. Racila[3], O. Spertini[1], S. Blum[1,*]
[1]Haematology, [2]Cytogenetics, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, [3]Haematology, University clinics Freiburg, Freiburg, Germany

Background: Myelodysplastic syndromes are heterogeneous diseases with variable probability of developing a transformation to acute leukaemia. The vast majority of these cases present a transformation to acute myeloid leukaemia. We here describe a series of 4 cases of MDS/CMML with evolution to acute lymphoblastic leukaemia. These events are very rare and are to date only published as single cases.
Aims: The aim of these study is to better define cases of MDS transforming to ALL.
Methods: We describe 4 cases of patients suffering from MDS who in the course of their disease presented with ALL. Three of these cases presented in 1 centre, 1 in the other, all cases were documented in a 17-year time span.
We than performed a literature research including at the moment 37 cases of MDS transforming to ALL described as case reports.
Results: Subtypes of MDS are varying from low risk MDS with deletion (5q) (del(5q)) to refractory anaemia with excess of blasts in transformation (RAEB-T), classified as AML in newer WHO classifications (2008 and 2016) and CMML, classified as MDS/MPS nowadays. Even if MDS subgroups are manifold, cytogenetic results are less so. Two of the 4 patients described demonstrated KMT2A rearrangements, 1 already at MDS presentation, the other at ALL presentation. One patient presented with del(5q). Of the 37 cases we identified in the literature, 7 presented with del(5q) and 2 showed with anomalies of the 11q23 locus.
Summary/Conclusions: KMT2A is known to be a gene involved in myeloid neoplasms as well as in acute lymphoblastic leukaemia. In a small series of cases like this one, it is not excluded that ALL following MDS is only by chance and "bad luck", but at least in the patient showing the same translocation at MDS presentation and at ALL presentation, both diseases seem to be related. MLL as a cytogenetic event enabling the disease a switch from one phenotype (myeloid) to the other (lymphoblastic) could be a possible explanation for this phenomenon. KMT2A rearrangement in MDS is an extremely rare event, but could explain part of these rare changelings of MDS transforming to ALL. Further studies are needed to confirm this hypothesis, and molecular examination is needed to characterise the event enabling a myeloid phenotype to switch to a lymphoblastic one. The reason why del(5q) seems to be present in a high proportion of MDS patients transforming to ALL is not clear, further studies need to be performed.

PB1925

IMMUNOSUPPRESSIVE THERAPY AS FIRST-LINE TREATMENT OF PATIENTS WITH PRIMARY MDS

N. Klimkovich[1,*], D. Suvorov[2], L. Kolbasko[2]
[1]hematology, Byelorussian Medical Academy of Post-Graduate Education, [2]hematology, Public Health Institution «Municipal Clinical Hospital № 9», Minsk, Belarus

Background: Myelodysplastic syndromes (MDS) are included into a heterogeneous group of clonal blood diseases characterized by peripheral cytopenias, dysplastic features of hematopoietic precursors, progressive deterioration and a high risk of transformation into leukemia. MDS occur in several versions that differ in frequency of appearance, the duration of the course and the probability of transformation into acute leukemia. The choice of therapy for a particular patient is determined by the morphological variant of the disease, the prognostic group, age and comorbidity. In hypoplastic cases of MDS are often used immunosuppressive therapy.
Aims: Analysis of the effectiveness of immunosuppressive therapy in patients with primary MDS
Methods: The research included 19 patients with primary MDS from 22 to 58 years (median age 46 years, 11 male, 8 female). The diagnosis was made according to the criteria of the WHO classification of myeloid neoplasms in 2008. The materials were taken only after signing by patients informed consent form to participate in the research. The calculations are performed in the R version 3.1.3 statistical package.
Results: There were patients with defined MDS subtypes: RA in 52,6%, RCMD in 31,6 and RAEB in 15,8%. Hypoplastic form of MDS were diagnosed in 63,2% patients. The increased number of lymphocytes in the bone marrow of patients were 52,6%, accumulation of lymphocytes in the bone marrow biopsy – in 36,8%. Cytogenetic abnormalities were found in 21% of patients (in 5,3% complex and in 15,7% isolated). All patients used immunosuppressive therapy as a first-line treatment: Antithymocyte globulin and Cyclosporine A (CsA) in 15,8%, monotherapy with CsA in 84,2%. CsA therapy started at a dose of 5 mg/kg per day. Dose correction performed depending on the concentration of CsA in the serum and toxicity. Median treatment was 143 days (36…1253 days). The response rate to CsA treatment was considered a complete remission (normalization of blood and bone marrow), partial remission (improvement of blood counts for more than 50% and no dependence on transfusions of blood components) or improvement (reduction in transfusion requirements by 50% or more). Complete remission was achieved in 10,5% of patients (only variant RA). Partial remission was obtained in 31,6% (variants RA and RCMD) and improvement in 36,8% (variants RA, RCMD and RAEB). There was no response to treatment in 21,1% of patients (variants RCMD and RAEB). Positive effect on immunosuppressive therapy significantly more likely achieved in patients with hypoplastic forms MDS (57,9%) and the presence of clusters of lymphocytes in the bone marrow biopsies (36,8%). Dependence of treatment efficiency and cytogenetic abnormalities not detected.
Summary/Conclusions: The effectiveness of immunosuppressive therapy in MDS associated with a variant of the disease, bone marrow cellularity and the bone marrow lymphoid infiltration. The greatest effect of the immunosuppressive therapy can be expected in patients with hypoplastic MDS and accumulation of lymphocytes in the bone marrow biopsy.

PB1926

VITAMIN D IS ASSOCIATED WITH SEVERITY OF DISEASE AS EXPRESSED BY SUBDIAGNOSIS AND IPSS-R IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND RELATED DISEASES

C. Müller-Thomas[1,*], H. Tüchler[2], J. Hecker[1], C. Wenk[1], C. Peschel[1], K. Götze[1]
[1]III. Medizinische Klinik, Klinikum rechts der Isar, TU München , München, Germany, [2]Ludwig Boltzmann Institute for Leukemia Research, Ludwig Boltzmann Institute for Leukemia Research, Wien, Austria

Background: Recent findings indicate that vitamin D (VD) might impact hypomethylating therapy of myelodysplastic syndromes (MDS). Epigenetic activity of VD is mainly mediated through interaction with its nuclear receptor (VDR). Activated VDR binds to specific genomic sequences (VD response elements) which influence gene transcription by histone modification, mainly acetylation but also demethylation. Among genes affected by VD/VDR is BGLAP encoding for the non-collagenous protein osteocalcin (OCN) produced by osteoblasts and implicated in osteogenesis. Furthermore, it has been shown that OCN is expressed by activated hematopoietic stem cells in hematological malignancies.
Aims: We initiated an exploratory study, collecting patients' data on serum VD, and osteocalcin (OCN)-levels in 59 unselected patients with MDS, MDS/myeloproliferative neoplasm (MPN) and secondary acute myeloid leukemia (sAML).
Methods: Serum VD levels were assessed by measuring 25-hydroxyvitamin D (25(OH)D), the biochemical indicator of VD status. Analysis was done by chemiluminescence immunoassay. Intact OCN is unstable due to protease cleavage between amino acids 43 and 44. The N-MID-fragment, resulting from cleavage, is considerably more stable. Measurement of both intact OCN and the stable N-MID-fragment was effectuated by electrochemiluminescence immunoassay.
Results: We found median serum 25(OH)D levels (normal range 30-100 ng/ml) of 16 ng/ml (RA, RARS, n=35), 23 ng/ml (RAEB-1/2, sAML, n=16), and 20 ng/ml (MDS/MPN, n=8) (p=0.273).When classified by IPSS-R, median serum 25(OH)D levels were 18 ng/ml in "(very) low" (n=20), 16.5 ng/ml in

"intermediate" (n=14), and 29.5 ng/ml in "(very) high" (n=6) with p=0.102.Regarding cytogenetic risk classification median serum 25(OH)D levels were 18 ng/ml in "(very) good" (n=48), 19 ng/ml in "intermediate" (n=8), and 18.5 ng/ml in "(very) poor" (n=4) cytogenetic risk patients (p=0.738).Median serum OCN levels (normal range 11-46 ng/ml) were 19 ng/ml (RA, RARS, n=33) and 16.2 ng/ml (higher-risk MDS/sAML, n=16), (p=0.136). IPSS-R risk classification resulted in median serum OCN levels of 17.4 ng/ml in IPSS-R "(very) low" (n=17), 16.2 ng/ml in "intermediate" (n=15), and 21.7 ng/ml in "(very) high" (n=6), (p=0.701). Cytogenetic risk classification had no impact on median serum OCN levels (p=0.271). We found median serum 25(OH)D levels (normal range 30-100 ng/ml) of 16 ng/ml (RA, RARS, n=35), 23 ng/ml (RAEB-1/2, sAML, n=16), and 20 ng/ml (MDS/MPN, n=8) (p=0.273). When classified by IPSS-R, median serum 25(OH)D levels were 18 ng/ml in "(very) low" (n=20), 16.5 ng/ml in "intermediate" (n=14), and 29.5 ng/ml in "(very) high" (n=6) with p=0.102. Regarding cytogenetic risk classification median serum 25(OH)D levels were 18 ng/ml in "(very) good" (n=48), 19 ng/ml in "intermediate" (n=8), and 18.5 ng/ml in "(very) poor" (n=4) cytogenetic risk patients (p=0.738). Median serum OCN levels (normal range 11-46 ng/ml) were 19 ng/ml (RA, RARS, n=33) and 16.2 ng/ml (higher-risk MDS/sAML, n=16), (p=0.136). IPSS-R risk classification resulted in median serum OCN levels of 17.4 ng/ml in IPSS-R "(very) low" (n=17), 16.2 ng/ml in "intermediate" (n=15), and 21.7 ng/ml in "(very) high" (n=6), (p=0.701). Cytogenetic risk classification had no impact on median serum OCN levels (p=0.271).

Summary/Conclusions: In summary, our cohort of patients with MDS, MDS/MPN and sAML show clearly decreased serum VD levels. The preliminary results suggest a tendency of serum VD levels to increase with higher risk MDS/sAML which is supported by positive Kendall's tau (0.210). Serum OCN levels lie below normal limits, but seem not to be affected by disease risk. These results suggest specific hypotheses regarding the pathomechanism that shall be investigated on an enlarged data set, which we are continuously collecting.

[1]Dokuz Eylül University, İzmir, [2]Gazi University, Ankara, [3]Ondokuz Mayıs University, Samsun, [4]Erciyes University, Kayseri, [5]Ankara University, Ankara, [6]İstanbul University, İstanbul, [7]Kocaeli University, Kocaeli, [8]Ankara Children's Hematology and Oncology Training and Research Hospital, Ankara, [9]Akdeniz University, Antalya, [10]Dr. Behçet Uz Children Training and Research Hospital, İzmir, [11]Necmettin Erbakan University, Konya, [12]Uludağ University, Bursa, [13]Ege University, İzmir, [14]Şişli hamidiye Etfal training and Research Hospital, [15]Bahçeşehir University, [16]Marmara University, İstanbul, [17]Karadeniz Technical University, Trabzon, [18]Tepecik Training and Research Hospital, İzmir, Turkey

Background: Juvenile myelomonocytic leukemia (JMML) is a chronic malignant myeloproliferative disease of early childhood
Aims: To define the status of juvenile myelomonocytic leukemia (JMML) patients in Turkey, in terms of time of diagnosis, clinical characteristics, mutational studies, clinical course and treatment strategies.
Methods: Data including clinical and labarotory characteristics and treatment strategies of JMML patients were collected retrospectively from pediatric hematology-oncology centers in Turkey.
Results: Sixty-five children with JMML diagnosed between 2002 and 2016 in 18 institutions throughout Turkey were enrolled into the study. The median age at diagnosis was 17 months (range, 2-117 months). Splenomegaly was present in 92% of patients at the time of diagnosis. The median WBC, monocyte and platelet counts were, $32.9x10^9$/L, $5.4x10^9$/L and $58.3x10^9$/L, respectively. Monosomy 7 was present in 18% of patients. JMML mutational analysis was performed in 32 out of 65 patients (49%), *PTPN11* was the most common mutation. Hematopoetic stem cell transplantation (HSCT) could only be performed in 28 (44%) patients, majority of being after the year 2012. The most frequent reason for not performing HSCT was the inability to find a suitable donor. The median time from diagnosis to HSCT was 9 months (range,2-63 months). The 5-year cumulative survival rate was 33% and median estimated survival time was 30±17.4 months (95% CI:0-64.1) for all patients. Survival time was significantly better in the HSCT group (log-rank p=0.019). Older age at diagnosis (>2 years), platelets less than $40x10^9$/L and *PTPN11* mutation were the factors significantly associated with shorter survival time.
Summary/Conclusions: Although there has recently been improvement in terms of definitive diagnosis and HSCT in JMML patients, the overall results are not satisfactory and it is necessary to put more effort into this issue in our country.

PB1928

THE PRECURSOR B CELLS AS A PROGNOSIS FACTOR IN MYELODYSPLASTIC SYNDROMES

G. Pinto[1,*], P. Herrera[1]
[1]Hematology, Hospital Ramon y Cajal, Madrid, Spain

Background: Recently, an immunosuppressive enviroment with low number of precursor B cells at the bone marrow has been related with poor survival in patients with very low/low and intermediate risk myelodysplastic syndrome (MS), but this negative impact is unclear yet.
Aims: The objetive of this study is to establish if there is an negative association between the percentage of precursor B cells (%PBC) at the time of diagnosis of MS and progression-free survival.
Methods: We analyzed 48 patients with IPSS-R very low/low risk (VL/L) and 34 patients with intermediate risk (INT) in the past 10 years in a single institution in Spain. We reviewed the%PBC CD34+ (CD34+CD10+ or CD34+CD117-) over total marrow cells at diagnosis measured by flow cytometry, and we calculated the time of progression-free survival (PFS) defined as the time between inclusion until progression to refractory anemia with excess blasts type 2 (RAEB-2) or acute myeloid leukemia (AML). The Competing risks regression test was used to assess the predictive value of PBC in relationship to PFS.
Results: Median age in both groups was 69 years, and median of progression to RAEB-2 or AML was 1,96 years in VL/L group and 0,64 years in INT group. The%PBC was not a predictor of PFS in VL/L group with a sub-hazard ratio (SHR) of 0,23 (95% CI: 0,003-13,96, P=0,485) neither in the INT group with a SHR 0,14 (95%CI: 0,001-4,52, P=0,211). We also performed a median split analysis fo the%PBC with a median value of 0,1% in both groups. In the VL/L group, patients with a%PBC above the median had a median PFS of 2,48 years *versus* 1,99 years for the patients with%PBC below the median. In the INT group, patients with a%PBC above the median had a median PFS of 1,14 years *versus* 0,83 years for the patients with%PBC below the median (Figure 1).

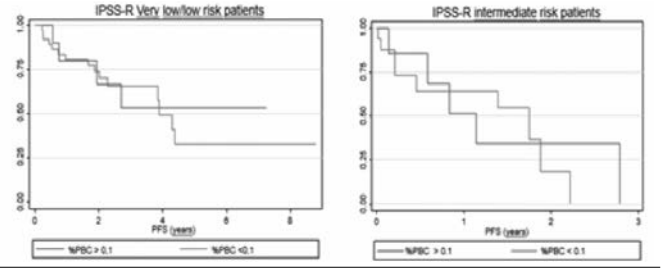

Figure 1.

Summary/Conclusions: Our results not provide evidence in order to establish a prognostic value between%PBC at diagnosis in IPSS-R very low, low or intermediate MS.

PB1929

TO INFINITY AND BEYOND: NGS IN MDS

A. Barbosa Ribeiro[1,2,3,*], R. Tenreiro[1], M. Coucelo[1], A.T. Simões[1], S. Marini[1], L. Ribeiro[1], E. Cortesão[1,2,3], A.B. Sarmento Ribeiro[1,2,3,4]
[1]Department of Clinical Hematology, Centro Hospitalar e Universitário de Coimbra, [2]Centre of Investigation in Environment, Genetics and Oncobiology – CIMAGO, [3]Applied Molecular Biology and University Clinic of Hematology, Faculty of Medicine, University of Coimbra, [4]CNC.IBILI, University of Coimbra, Coimbra, Portugal

Background: Myelodysplastic syndrome (MDS) constitutes a heterogeneous group of hematopoietic stem cell disorders, characterized by peripheral blood cytopenias in the presence of a dysplastic and hypercellular bone marrow. This biological heterogeneity is reflected in the clinical course, ranging from an indolent disease to entities with high risk of progression to AML and dismal prognosis. Genetic and epigenetic abnormalities are at the core of myeloid neoplasias development and despite the degree of dysplasia and blast percentages still being the main features for the WHO classification, a large amount of data has recently become available on recurring mutations in MDS, mainly due to massive parallel sequencing techniques.
Aims: Our aim was to search for genetic mutations in a cohort of patients with MDS.
Methods: We studied a total of 33 patients diagnosed with *de* novo MDS (WHO 2008 classification), using a Next Generation Sequencing panel comprising 45 myeloid genes.
Results: Patients were 15 male and 18 female, with a median age at diagnosis of 76 years (52 – 93 years). The MDS subtypes distribution was 16 patients (48,5%) with RCMD, 4 patients with RARS, 4 with RAEB -1 and 4 with RAEB-2 (12,1% for each subtype), 3 patients (9,1%) with 5q-Syndrome and 2 patients (6,1%) with RCUD. These patients were stratified according to the IPSS as Low-risk (24,2%), Int-1 (33,3%) and Int-2 (18,2%), without any high-risk

patients. All patients required erythropoiesis stimulating agents and 9 patients received treatment with azacytidine (AZA), including all the Int-2 patients and 3 lower risk patients who progressed to a higher risk MDS. Estimated cumulative survival at 46 months was 67% with a median OS not reached and median follow-up time of 34 months. Patients receiving AZA revealed a trend towards survival benefit (mean survival 54,2 *vs* 50 months), independent of IPSS and R-IPSS, but not statistically significant. Mutational analysis revealed that 75,8% of patients had at least one gene mutation and it was most frequently related to DNA methylation genes (n=14), particularly in TET2 (n=7 patients) and DNMT3A (n=6 patients, 7 different mutations) genes. We found a statistically significant difference between mutations in these genes and lower absolute neutrophil counts (mean 2,42±0,47 G/L *vs* 1,33±0,18 G/L; p=0,42). The second most frequently mutated genes were related to signal transduction pathways (n=11; JAK1, JAK2, NRAS, CBL, GATA2, SH2B3, CSFR). Patients with these mutations had significantly lower serum EPO levels (p <0,001; median 32,35 *vs* 42,70 U/L). Furthermore, patients with such mutations demonstrated a clear disadvantage in survival analysis, with a median OS of 19 months *vs* not reached in patients without mutations (p<0,001), being these results independent of the IPSS and R-IPSS risk groups. We were also able to identify a trend towards worst survival in patients with previously described high risk mutations (TP53, EZH2, ASXL1, RUNX1 and ETV6 genes).

Summary/Conclusions: We conclude that the most frequently detected mutations were related to DNA methylation genes, as described in the literature, which was independent of the IPSS risk group, being observed in both low-risk and high-risk patients. These results raise the question whether hypomethylating agents may also be of benefit for lower-risk patients.

We also observed a high frequency of mutations in signal transduction pathways which was related to a clear survival disadvantage across all risk groups of the IPSS and R-IPSS. This unveils the question whether we may be facing a shift towards the molecular level in MDS risk stratification and if therapies targeted to such molecules may improve the outcome of these patients.

PB1930

CLINICAL FEATURES, CYTOGENETIC STUDY AND OUTCOME OF ADULT MYELODYSPLASTIC SYNDROMES: REVIEW OF 101 CASES, A SINGLE CENTER EXPERIENCE IN ALGERIA.

S. Taoussi[1,*], Y. Bouchakor-Moussa[1], M.T.T. Abad[1]
[1]Hematoloy, EHS ELCC CAC, Blida, Algeria

Background: Myelodysplastic syndromes (MDS) are heterogeneous disorders defined as clonal diseases involving hematopoietic stem cells and even characterized by cytopenias, with a high risk of leukemic transformation. Morphological analysis of peripheral blood (PB) and marrow aspirates or bone marrow biopsies is the first step that ensures a diagnosis of MDS. Cytogenetic studies are important means of defining different prognostic groups and even of showing how patients are eligible for this or that treatment. We conducted the first study including conventional karyotyping and fluorescent *in situ* hybridization (FISH) for MDS in our country.

Aims: Our study was aimed to evaluate outcome of MDS regarding IPSS and IPSS-R classification in an emerging country.

Methods: Between January 2012 to December 2016, 101 patients with MDS were consecutively diagnosed. Frequent genetic abnormalities in MDS were screened by R-banding karyotype , metaphase and interphase FISH using a panel including six probes (5q-,7q-,20q-, del(17p13), MLL, Inv(3) t(3;3). Patients were stratified into risk groups according to IPSS and IPSS-R scores; survival probabilities were estimated using the Kaplan-Meier method.

Results: Among these 101 pts, 58 were male with a sex ratio=1, 35; range in age is from 18 years to 94 years with a median of 61, 6 years. Median hemoglobin value was 80 g/L (29-150), more than 60% of patients had severe anemia mainly in the low risk group; the median absolute neutrophil count was 3 G/L (0,060-13, 5), and the median platelet count was 144 G/L (5-659). Median bone marrow blast value was 4% (0-18). Cases were classed by cytomorphology FAB as RA (N=45), REAB (n=34), RARS (n=16), other (n=6). Classification by WHO 2008 included RCUD (n= 31 of which RA: 18, RT : 10, RN : 3), RCMD (n= 16), RAEB-1 (n=22), RAEB-2 (n= 13), RARS (n= 15), Isolated 5q- (n=4). Among 101 patients, cytogenetic abnormalities by R banding karyotype (n= 84) and FISH (n=101) were found in 41 cases (41%) distributed as single anomaly (n=19), double anomaly (n=5) and complex (n=17). The main cytogenetic abnormalities seen were isolated 5q deletion (n=4), isolated 7q deletion (n=2), isolated 20q deletion (n= 6), isolated trisomy 8 (n=2), 17p13 deletion (n=6), - Y (n=1), complex aberrations ≥3 (n=6), complex aberrations ≥5 (n=6), complex aberrations ≥7 (n=5), others (n=3). IPSS was assessed in 84 patients: 27% (low risk), 44% (intermediate 1) , 24% (intermediate 2), 5% (high risk). IPSS-R was assessed in 84 patients (18% very low risk, 30% low risk, 22,5% intermediate, 15,5% High risk, 14% very High risk). Leukemic transformation into AML occurred in 33% of patients in a median time of 12 months. According to IPSS, the median OS time survival is not reached for low risk group, 41 months (m) for Intermediate 1 risk, 11 m for Intermediate 2 risk, and 4 m for High risk. According to IPSS-R, the median OS time survival is not reached for Very low risk, 43 m for low risk, 24 m for Intermediate risk, 18 m for High risk and 4 m for very high risk.

Summary/Conclusions: Our results are in agreement with those previously published regarding demographic features, distribution of recurring cytogenetic abnormalities and prediction of survival. Myelodysplasias are among the most difficult hematological diseases to treat. Treatment of low risk and high risk myelodysplasia are completely different, the last group carrying a great risk of leukemic transformation. For all these reasons, application of the new tools to classify MDS is of a major importance. This is especially true in emerging countries where few therapeutic means are available, hence the need to predict the prognosis of these diseases in order to better target treatments. To the best of our knowledge, it is the first study conducted in our country.

PB1931

IS PRE-TRANSPLANT THERAPY A KEY FACTOR IN INFLUENCING POST TRANSPLANTATION RELAPSE INCIDENCE IN EXCESS BLAST MYELODYSPLASTIC SYNDROMES? A SINGLE CENTRE EXPERIENCE

G. Bertani[1,*], G. Grillo[1], M. Riva[1], E. Zucchetti[1], E. Ravano[1], B. Forno[1], I. Lotesoriere[1], L. Crucitti[1], R. Cairoli[1]
[1]Haematology, Ospedale Niguarda Ca' Granda, Milano, Italy

Background: The importance of pre-transplant disease burden in myelodysplastic sindromes (MDS) as a factor influencing post hematopoietic cell transplantation (HCT) outcome is an important argument of debate. It has been reported that relapse rate (RR) after transplant is reduced in patients entering HCT with a blast cell count <5%. However, the effect of a pre-transplant debulking therapy in reducing RR has not been clearly demonstrated.

Aims: Here we review our data to evaluate if the intensity of pre-transplant therapy may have influenced post transplant RR.

Methods: In our Institute, we treat all patients with a blast cell count of 10% or higher with a debulking therapy pre-transplant. This is usually an AML-like, cytarabine and anthracycline based, intensive chemotherapy (I.C.). In selected cases fludarabine and cytarabine containing regimens are also used. In the last ten years, in the context of a clinical trial, a series of patients have received a less intensive, hypometilating therapy (repeated courses of 5-azacytidine 75 mg/m^{2}subcutaneously for 7 days), as bridge to transplant. Conditioning regimen used in MDS patients is busulfan based in younger patients (Bu-Flu, BU-Cy); in the elderly or less fit patients a RIC regimen (thiotepa 5 mg/kg e.v., fludarabine mg/m^{2}x 3 and L-PAM 100 mg/m^2) is administered.

Results: In the last ten years we performed 14 HCT (between June 2008 and september 2016) in patients with MDS with excess blasts. Median patients age was 63,5 years (range: 49-69), male/female ratio was 9/5. According to IPSS, 12 out of 14 patients were high/ int-2 (2 int-1), 11/14 had >10% blast cells (EB-2). According to our centre protocol, we treated 11 patients with EB-2 and 1 patient with EB-1 (with hypercellular bone marrow) with a debulking therapy. This was I.C. in 6 patients and 5-AZA in 6 patiens. Two patients with EB-1 did not receive any therapy pre-transplant. However, both of them are not evaluable, due to early mortality. Transplant conditioning was RIC in 11/14 patients, myeloablative in 3 cases. The donor was a sibling in 9/14, MUD in 5/14. Four out of six patients treated with I.C. achieved a pre-transplant CR (67%), compared to one out of six in the 5-Aza cohort (17%). Four patients experienced a relapse post HCT, after a median of 8,5 months (4-11). With a median follow up of 21 months (6-68), post transplant RR was 4/12 (33,3%) and was not influenced by debulking therapy (I.C. *vs* 5-Aza, p=0,54), nor by pre-transplant disease state (CR *vs* noCR, p=0,22). In fact, 3 out of 6 patients treated with I.C., but only 1 out of 6 treated with 5-Aza relapsed after transplant. Three out of four patients who subsequently relapsed had recived RIC transplant; type of transplant was not assocaited with relapse (P=1,0) The only variable that showed a trend for reduced RR was MUD transplant (p=0,08).

Summary/Conclusions: Extreme caution must be used in considering our data, given the very small patients number. In our cohort, pre-transplant intensive debulking chemotherapy, although obtained an high rate of CR, showed no effect in preventing relapse. Larger studies are necessary to assess the real utility of I.C. in this subset of frail patients.

PB1932

IRON CHELATION THERAPY IN MYELODYSPLASTIC SYNDROMES AND IN OTHER TRANSFUSION-DEPENDENT CHRONIC ANEMIAS. RETROSPECTIVE STUDY OF 69 PATIENTS FROM A SINGLE INSTITUTION

C. Finelli[1,*], C. Clissa[2], M. Barraco[1], C. De Maio[1], M. Stanzani[1], S. Parisi[1], S. Paolini[1], C. Bosi[3], M. Cavo[1]
[1]Hematology, S.Orsola-Malpighi University Hospital, Bologna, [2]Hematology, S. Salvatore Hospital, Pesaro, [3]Hematology, Guglielmo da Saliceto Hospital, Piacenza, Italy

Background: Although several recent guidelines recommend iron chelation therapy (ICT) for iron overload in transfusion-dependent patients (pts) with lower-risk myelodysplastic syndromes (MDS), several barriers may limit the initiation or the continuance of ICT: older age, comorbidities, poor tolerance and compliance.

Aims: Therefore, with the aim of assessing the safety and efficacy of ICT in the daily clinical practice, we retrospectively analyzed our single-center experience on ICT in MDS and other chronic anemias.
Methods: From October 1997, in our Institution, 69 pts (48 males), median age: 74 (23-96) yrs, with transfusion-dependent anemia, received ICT, because of a diagnosis of iron overload, *i.e.* both a transfusion history of at least 20 units of RBC and a serum ferritin (SF) higher than 1000 ng/ml.
Results: 40 pts (58%) were affected by lower-risk MDS (IPSS risk: low or intermediate-1), while 13 pts (18.8%) showed a higher-risk MDS (IPSS risk: high or intermediate-2) but were considered for ICT because of responsiveness to hypomethylating therapy and/or elegibility for allogeneic SCT. 16 pts (23.2%) were affected by other diseases (chronic myelomonocytic leukemia: 2 pts; idiopathic myelofibrosis: 3 pts; aplastic anemia: 9 pts; pure red cell aplasia (PRCA): 2 pts). 45 pts (65.2%) received deferasirox (DFX) as first-line treatment, 12 pts (17.4%) received DFX after a previous treatment with deferoxamine (DFO), while 9 pts (13%) received DFO and 3 pts (4.3%) received DFO after DFX because of contraindications to DFX or toxicity. Median time from diagnosis to the start of ICT: 18 months. Median number of RBC transfusions before the start of ICT: 37.5. Median SF level pre-ICT: 1964 ng/ml; median SF after ICT (last value): 1858 ng/ml; median duration of ICT: 12 (range 1-230) months. 36 pts (52.2%) continued ICT for a period ≥12 months, and 25 pts (36.2%) for a period ≥24 months. 27 pts (39.1%) showed a drop of SF ≥500 ng/ml, 11 pts (15.9%) showed a drop of SF <500, 13 pts (18.8%) showed an increase of SF <500, in spite of ICT, and 18 pts (26.1%) showed an increase of SF ≥500. 12 pts (17.4%) achieved a SF value <1.000, and 48 pts (69.6%) a SF value <2.500. Adverse events possibly related to DFX were observed in 30 pts (43.5%): renal (increase of serum creatinine): 14 pts (20.3%) (grade >2: 1 pt: 1.4%); gastrointestinal : 14 pts (20.3%) (grade >2: 1 pt: 1.4%); cutaneous: 2 pts (2.9%) (grade >2: no pts). Permanent discontinuation of ICT: 40 pts (58%), because of toxicity (16 pts: 23.2%), worsening of clinical condition (6 pts: 8.7%), discontinuation of transfusions (9 pts: 13%), allogeneic transplantation (9 pts: 13%). 5 pts (7.2%) (4 MDS and 1 PRCA) (with DFX: 4 pts; with DFO: 1 pt) showed an erythroid response following ICT, after 2, 4, 7, 32 and 112 months, respectively, and one of them (with PRCA) achieved complete remission. 35 pts (50.7%) died, because of infection (9 pts), AML (4 pts), cachexia (4 pts), other neoplastic diseases (3 pts), hemorrhage (2 pts), heart failure (2 pts), stroke (2 pts) and other causes (9 pts). 10 pts (14.5%) are still receiving ICT. With a median follow-up of 34 (2-230) months, median overall survival (OS) was 64 months for all pts, 51 months for MDS pts, 87 months for lower-risk MDS (IPSS risk: low and intermediate-1) and 24 months for higher-risk MDS (IPSS risk: intermediate-2 and high).
Summary/Conclusions: In conclusion, in our experience ICT appears feasible and effective, in terms of reduction of SF and OS, even in a population of elderly pts, if carefully selected.

PB1933

VCAM-1 AS A NOVEL DRUG THERAPY TARGET OF BONE MARROW MESENCHYMAL STEM CELLS IN MULTIPLE MYELOMA

A. Ortiz-Ruiz[1,*], C. Alicia[2], L. Alejandra[2], M.Mª Luz[2], L. Maria[2], G. Miguel[1], M.-L. Joaquin[2]
[1]Haematological Malignancies Clinical Research Unit, CNIO, [2]Hematologia Traslacional, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Multiple myeloma is characterized by the clonal proliferation of malignant plasma cells in the bone marrow microenvironment. The pathogenesis consists, in part, in critical interactions between myeloma cells and the mesenchymal stem cells (MSC). The interactions between myeloma cells and bone marrow cells are establish through surface receptors (*e.g.* integrins, cell adhesion molecules, etc.), which determine tumor growth, survival, migration and drug resistance. Mesenchymal stromal cells modulate the pattern of myeloma markers on the cellular surface *in vitro* towards a less differentiated phenotype. However, the exact mechanism by which mesenchymal stromal cells carry out their functions is not yet fully understood.
Aims: To evaluate the effect of MSCs from healthy donors and myeloma patients over malignant plasma cells and the molecular changes produced for the interaction each other.
Methods: Interactions between both cell types were studied through different co-cultures studies. We evaluate differences between culturing primary MSC cells and MM cell line RPMi 8226. Pathological MSCs were extracted from the bone marrow of newly diagnose MM patients. On the other hand, purified healthy MSCs will be isolated from donor patients. Pathological or healthy MSCs were cultured and co-cultured 24h after seeding with MM plasma cells RPMI 8226 for duplicates at 24, 48 and 72h. The phenotypical and molecular effect of the interaction of both cells were characterized by viability through trypan blue, cell apoptosis percentage (7AAD) and variations on expression of cell surface proteins (MSCs: CD90, CD105, CD106 and CD54. MM cell: CD138, CD38, CD49d and CD11a) using flow cytometry, and statistically analyzed with GraphPad.
Results: We observed a decrease of apoptosis of MM plasma cells when are in co-culture with pathological MSCs at short-term (24h, 7AAD positive cells MM alone: 4.8%, MM in co-culture: 0.4%) and mid-term (72h, 7AAD positive cells MM alone: 16.4%, MM in co-culture: 10.7%) compared with MM plasma cells alone. However MM plasma cells not decreases the level of apoptosis at mid-term with healthy MSCs in co-cultures (72h, 7AAD positive cells MM alone: 16.4%, MM in co-culture: 18.0%). The molecular analysis showed a correlation between MSC lack of protection over MM plasma cells and the decrease in the levels of expression of VCAM-1 (CD106).
Summary/Conclusions: As reported in literature CD106 expression increase when MSCs are co-cultured with plasma cells. Adhesion of tumor cells to BMSC activates many pathways resulting in upregulation of cell cycle and anti-apoptotic proteins. MM pathophysiology is supported by a strong interaction between CD106/CD49d. Changes in VCAM-1 and VLA-4 expression have been demonstrated in cell lines assays, and were corroborated with primary cells in the context of MSCs protection over MM plasma cell. Thus, MM pathological MSCs did not change VCAM-1 levels and MM plasma cell protection be held. However, healthy MSCs have the capacity to modulate the VCAM-1 in mid-term to avoid the protection effect. Therefore, these results suggest MSCs VCAM-1 as potential drug therapy target in MM disease.

PB1934

RALA AND RALB MEDIATE CELL SURVIVAL INDEPENDENTLY OF ONCOGENIC RAS AND PROVIDE POTENTIAL THERAPEUTIC TARGETS IN MULTIPLE MYELOMA

M. Seibold[1,*], T. Stühmer[1], N. Schmiedl[1], D. Brünnert[1], A. Mottok[2], E. Leich[2], A. Rosenwald[2], C.-J. Scholz[3], M. Chatterjee[1], H. Einsele[1], R.C. Bargou[4], T. Steinbrunn[1]
[1]Department of Internal Medicine II, University Hospital of Würzburg, [2]Institute of Pathology, University of Würzburg, Würzburg, [3]Life & Medical Sciences Institute, University of Bonn, Bonn, [4]Comprehensive Cancer Center Mainfranken, University Hospital of Würzburg, Würzburg, Germany

Background: Genetic mutations and the bone marrow microenvironment contribute to disease progression, aggressive phenotype, and shorter survival in multiple myeloma (MM). Oncogenic RAS is one of the most common mutations in MM. Pathway activation through oncogenic RAS is associated with promotion of disease progression and shorter survival. Cell survival and proliferation in MM are mainly mediated via classical signaling pathways such as MEK/ERK and PI3K/Akt. Since there is a lack of specific RAS-inhibitors for clinical use, it is important to identify and analyze associated pathways, which may provide useful alternative targets for MM therapy. The small GTPase Ral has previously

been implicated in putative downstream signaling of RAS, and may therefore promote proliferation, survival and drug resistance of MM cells.
Aims: We used shRNA-mediated knockdown of RalA and RalB isoforms to appraise their role as potential therapeutic targets and to analyze their connection to important signaling pathways, which regulate MM cell survival and proliferation. Because oncogenic RAS is a potential activator of the Ral pathways, we investigated a possible link between oncogenic RAS and Ral.
Methods: Immunohistochemical stainings of bone marrow trephines of MM patients and Western analysis of primary MM cells and MM cell lines were performed to evaluate Ral protein expression. Transient or stable knockdown of RalA or RalB was achieved by electroporation of MM cell lines and the effect on cell survival and apoptosis was measured with flow cytometry using annexin V/propidium iodide staining. Ral pulldown assays were applied to test potential dependence of Ral activation on oncogenic RAS. Furthermore, RNA sequencing was performed to compare RAS and Ral gene expression signatures after respective knockdowns.
Results: Both Ral isoforms were expressed in primary MM cells and MM cell lines, with RalA showing the most prominent and consistent protein expression levels. ShRNA-mediated knockdown of RalA strongly induced apoptosis in two thirds of the tested cell lines, whereas RalB depletion did impair MM cell survival in less than half of the cell lines. Western analysis revealed no alteration of classical MEK/ERK and PI3K/Akt pathway activation after Ral knockdown. Ral activity appears to be independent of oncogenic KRAS or NRAS. In addition, RNA sequencing revealed differing gene expression signatures for RAS and Ral.
Summary/Conclusions: Ral and its effector network constitute potential therapeutic targets in MM, which are activated independently of oncogenic K- or NRAS. Therefore, investigation of the functional network of Ral may be important to identify useful clinical targets.

CXCR4 MUTATIONS FOUND BY USING DEEP SEQUENCING WITHOUT SORTING B CELLS, AND PROGNOSTIC IMPLICATION IN WALDENSTROM MACROBULINEMIA

S.-M. Kim[1,*], D.W. Shin[2], K. Im[1], S.M. Hwang[3], J.-A. Kim[2], H.S. Park[2], D.S. Lee[2]
[1]Cancer Research institute, [2]Department of Laboratory Medicine, Seoul National University College of Medicine, Seoul, [3]Department of Laboratory Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of

Background: Waldenstrom macroglobulinemia (WM) is a lymphoplasmacytoid lymphoma with IgM monoclonal gammopathy. Most of WM harbor *MYD88 L265P* and one thirds of WM with *MYD88* present *CXCR4* mutations. Currently, frequency of *CXCR4* mutations and its clinical implication is not reported in Asian patients with WM.
Aims: We investigated the profiles of *CXCR4* and *MYD88* mutation in correlation with prognostic implication. To detect minor cell population with *CXCR4* mutation, we adopted a ultra-deep sequencing strategy for *CXCR4*, which can detect specific variants <1% of the cell population.
Methods: Allele-specific PCR for *MYD88* was performed on 37 patients with WM, along with 161 patients with B-cell neoplasms [diffuse large B-cell lymphoma (DLBCL), B-cell acute lymphoblastic leukemia (B-ALL), chronic lymphocytic leukemia (CLL)]. Deep-sequencing for *CXCR4* and interphase fluorescent *in situ* hybridization (FISH) for 6q deletion was performed on 31 patients with WM. Clinicopathologic features were compared among 3 groups according to *MYD88* and *CXCR4* mutation status (Group 1, $MYD88^{WT}$ and $CXCR4^{WT}$; group 2, $MYD88^{L265}$ and $CXCR4^{WT}$; group 3, $MYD88^{L265P}$ and $CXCR4^{Mutation}$; statistical comparison, Fisher exact test, one-way ANOVA).
Results: *MYD88 L265P* mutation was detected in 81.3% (26/32) patients with WM, 10.8% (9/83) in patients with DLBCL, 9.5% (6/63) in patients with CLL, 0% (0/15) in patients with B-ALL, and 0% in 200 healthy persons. Among the 31 WM patients, 6 patients have *CXCR4* mutation (19.4%) in the c-terminal domain (Figure 1); 1 frameshift mutation and 5 nonsense mutations. Two variants, K327X and K331X, are novel and the rest were known reported sites. All of them had *MYD88* L265P mutation. FISH revealed 6q21 deletion in 14 patients (43.8%), and *IGH* rearrangement in 9 patients (28.1%). There was no correlation aming cytogenetic aberrations and genetic mutation (*MYD88* and *CXCR4*). IgM levels of group 2 ($MYD88^{L265}$ and $CXCR4^{WT}$) were significantly higher than that of group 1 ($MYD88^{WT}$ and $CXCR4^{WT}$) (*P*=0.024). Meanwhile, IgG level was significantly lower in group I, compared to group 3. Other clinical characteristics such as age, Hb, platelet, adenopathy, hyperviscosity showed no significant difference among 3 groups. Group I showed adverse survival and 1 year survival rate of group 1 (66.7%) was lower than group 2 (94.7%), though it was not statistically significant (*P*=0.410). There were no death events in group 3 ($MYD88^{L265P}$ and $CXCR4^{Mutation}$) patients during the research period.
Summary/Conclusions: The frequency of *CXCR4* mutation in Korean WM was similar to those of Caucasian. We suggest that ultra-deep sequencing using next generation sequencing can replace B cell sorting for the detection of *CXCR4* mutation. Patients with $MYD88^{WT}$ and $CXCR4^{WT}$ showed higher IgM level and lower survival, suggesting an adverse prognostic implication. This is the first report on *CXCR4* mutation in Korean WM patients.

THE CLINICAL IMPACT OF CHROMOSOMAL TRANSLOCATION T(14;16)(Q32;Q23) IN PATIENTS WITH MULTIPLE MYELOMA

L. Pavlistova[1,2,*], A. Berkova[1,2], Z. Zemanova[2], K. Svobodova[2], S. Izakova[2], S. Ransdorfova[3], I. Spicka[1], J. Straub[1], K. Michalova[2,3]
[1]1st Medical Department, [2]Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General University Hospital and First Faculty of Medicine, Charles University in Prague, [3]Department of Cytogenetics, Institute of Hematology and Blood Transfusion, Prague 2, Czech Republic

Background: Translocation t(14;16)(q32;q23) in plasma cells is considered as a strong negative prognostic factor in patients with multiple myeloma (MM). The oncogenic potential of this chromosomal aberration is based on the overexpression of the c-*MAF* protooncogene (located at 16q23) under strong enhancer of *IgH* gene (14q32). Although the *IgH/MAF* positive cases comprise just 2-4% of MM patients, the evaluation of this aberration is an integral part of the cytogenetic risk stratification according the RISS. The International Myeloma Working Group (IMWG) proposed a model of high risk MM as having at least one of the following aberrations: deletion of 17p13 (*TP53* gene), translocation t(4;14)(p13;q32) and translocation t(14;16)(q32;q23) determined by FISH. However, the unequivocal poor prognostic value of t(14;16)(q32;q23) was not confirmed in several MM series thus further studies are needed.
Aims: The aim of our study was to assess the impact of t(14;16)(q32;q23) on event free (EFS) and overall survival (OS) in cohort of *IgH/MAF* positive MM patients in comparison with control group of 30 MM *IgH/MAF* negative cases.
Methods: During the years 2004 to 2016, we examined 870 bone marrow samples of MM patients on immunofluorescently labeled plasma cells (clg FISH). The basic FISH panel included 4 specific DNA probes (Abbott-Vysis, Kreatech and MetaSystems) detecting: the *IgH* gene rearrangement (1), deletion 13q14 (*RB1* gene)/monosomy 13 (2), gain of 1q21/deletion of 1p32 (3) and deletion of *TP53* gene (4). Cases with rearranged *IgH* gene were gradually examined for 3 specific translocations- 1) t(11;14)(q13;q32), 2) t(4;14)(p16;q32) and 3) t(14;16)(q32;q23). Kaplan-Maier analysis was performed to evaluate OS and EFS.
Results: Translocation t(14;16) was identified in 19 out of 870 patients (2.2%). Eighteen patients were examined at the time of diagnosis and one at the time of the progression of asymptomatic myeloma to symptomatic disease. Relapse and/or disease progression occurred in 15 patients. The median event-free survival (EFS) was 13 months in t(14;16) carriers (range 3 – 62 months) and 22.5 months in controls (range 3-71 months, p=0.285). Fourteen t(14;16) positive patients died. The median overall survival (OS) was 25 months (range 10-204 months) in comparison with 52 months in control group (range 3-132 months). However, the difference in OS was not statistically significant (p=0.155). In 15 t(14;16) positive patients (83.3%), two or more additional chromosomal changes were detected by FISH (monosomy/deletion of chromosome 13 being the most frequent). In four cases, (14;16) was detected together with another high risk chromosomal change - deletion of *TP53* gene - and all these patients died within median of OS 12.5 months (range 10-16).
Summary/Conclusions: Beside its supposed negative clinical impact, the examination of t(14;16) is not always included in routine diagnostics of chromosomal changes and its prognostic significance should be proved in large series of MM patients. Our data substantiate the trend of worse clinical outcome (shorter OS) in t(14;16) positive group compared to *IgH/MAF* negative MM controls. The detailed analysis of other clinical parameters, type of therapy, combination with other chromosomal aberrations will be performed to prove its role of as independent prognostic factor.
Supported by grants RVO-VFN64165, ProgresQ28 and GACR P302/12/G157.

PB1937

THE ROLE OF NEUROTROPHINS AND ANGIOGENIC CYTOKINES IN THE PATHOPHYSIOLOGY OF PERIPHERAL NEUROPATHY IN PATIENTS WITH MULTIPLE MYELOMA

K. Łuczkowska[1,*], Z. Litwińska[1], E. Pius-Sadowska[1], A. Sobuś[1], E. Paczkowska[1], B. Machaliński[1]
[1]Department of General Patology, Pomaranian Medical University in Szczecin, Szczecin, Poland

Background: The introduction of new treatment modalities have changed significantly the prognosis of multiple myeloma (MM) patients. The novel drugs and schemes of treatment of MM have contributed to substantial extend of the overall survival time of patients. However, the administration of some of the treatments, *e.g.* thalidomide or bortezomib, is also associated with occurrence of a serious and common side-effect problem, which is the drug-induced peripheral neuropathy. The mechanism of the development of the peripheral neuropathy is poorly understood. Nevertheless, one of its potential cause, could be inadequate concentrations of crucial trophic factors, including neurotrophic and/or angiogenic factors, which are responsible for proliferation, differentiation, survival and death of neuronal and nonneuronal cells.
Aims: The aim of this study was to elucidate the potential relationship between concentration of neurotrophic and angiogenic factors and development of peripheral neuropathy in the natural clinical course of the disease and, especially, induced by treatment regimen: VMP (bortezomib, melphalan, prednisone) or VTD (bortezomib, thalidomide,dexamethason) in patients with MM.
Methods: Peripheral blood samples were collected from patients classified into two groups: i) patients with multiple myeloma, without neuropathy and before therapy; and ii) patients with peripheral neuropathy 3^{o}or 4^{o} induced in the course of VMP or VTD therapy. The control group consisted healthy aged matched subjects. Assessment of concentrations of neurotrophins (BDNF, NSE) and angiogenic factor (PDGF) were performed using Luminex technology, which utilize microbeads coated with fluorescently labeled antibodies.
Results: Concentration of BDNF, PDGF and NSE were significant decreased in patients after treatment regimen involving VMP or VTD who have developed peripheral neuropathy grade 3 or 4, compared with patients with newly diagnosed MM without neuropathy, before therapy and control healthy group. Additionally, plasma levels of both neurotrophins and PDGF in patients before therapy were higher, then in control group. Obtained results may be caused by the changes in an activity of the transcription factor NF-κB during the treatment of MM, since reduction of NF-kB concentration is associated with decrease in the transcription of genes encoding BDNF, NSE and PDGF.
Summary/Conclusions: Alterations in the concentration of BDNF, PDGF and NSE suggest the cause and effect relationship between these factors and the development of neuropathy in patients with MM. Comprehensive elucidation of this phenomenon may contribute to the extension of the knowledge concerning the pathogenesis of neuropathy, and might well lead to reduction of the incidence of polyneuropathy in MM patients in the future.

PB1938

INFLUENCE OF XRCC5, XRCC4, NFKB2, AND BIRC5 GENES POLYMORPHISMS IN THE RISK AND PROGNOSIS OF MONOCLONAL GAMMOPATHIES

L. Balanco[1], M.S. Melo[1], A.C. Gonçalves[1,2], R. Alves[1,2], C. Geraldes[1,2,3], E. Cortesão[1,2,3], L. Ribeiro[3], L. Mota-Vieira[4], A.B. Sarmento-Ribeiro[1,2,3,*]
[1]Applied Molecular Biology and University Clinic of Hematology, [2]CIMAGO, Faculty of Medicine University of Coimbra, [3]Clinical Hematology Department, Centro Hospital e Universitário de Coimbra (CHUC), Coimbra, [4]Molecular Genetics and Pathology Unit, Hospital do Divino Espírito Santo de Ponta Delgada, EPER, Ponta Delgada - Azores, Portugal

Background: Monoclonal gammopathies (MG) are a group of disorders characterized by the proliferation of monoclonal plasma cells, which produce and secrete monoclonal immunoglobulin (M protein). Symptomatic multiple myeloma (MM) is characterized by the clonal proliferation of plasma cells. MM is consistently preceded by a pre-neoplastic entity, called monoclonal gammopathy of undetermined significance (MGUS), with an intermediate phase of indolent multiple myeloma (MMI). This disease is a heterogeneous hematological neoplasm characterized by the proliferation of clonal, long-lived plasma cells within the bone marrow (BM) secreting monoclonal proteins and by the presence of so-called CRAB criteria and/or biomarkers of malignancy (as clonal BM plasma cells ³ 60%, involved:uninvolved serum free light chain ratio ³100, >1 focal lesion in MRI studies). Genetic instability and several molecular abnormalities are hallmarks of MM cells. Alterations in DNA repair pathways, namely abnormal activity of non homologous end–joining (NHEJ) repair pathway, are involved in the disease onset and progression. Moreover, it has been observed that virtually all primary MM samples have constitutive nuclear factor-κB (NF-κB) pathway activity, having this pathway a well–established role in MM pathogenesis.
Aims: In this context, we hypothesized that polymorphisms of genes involved in NHEJ repair pathway (XRCC5, XRCC4) and in NF-κB pathway (NFKB2, and BIRC5) may have impact in MG susceptibility and prognosis.
Methods: In the present, a hospital-based case-control study, we analyzed eight polymorphism in four genes (XRCC5, XRCC4, NFKB2, and BIRC5), by genotyping 189 individuals (63 MG patients and 126 controls) using TaqMan qPCR. Results are expressed in terms of frequencies of allele, genotype, haplotype, and genotypic profiles, and their correlation with MG susceptibility. The strength of association between polymorphisms and disease risk was assessed by odds ratio (OR) with 95% confidence interval (CI95%) calculated by logistic regression. We also investigated the association of these SNPs with overall survival through Kaplan Meier curves. All statistical analyses had a significance levels of 95%.
Results: In the patient group, 51% (32/63) of the individuals were females and 49% (31/63) were males; the mean age was 70.11±10.25 years old. Among the control group, 52% (65/126) of the individuals were females and 48% (61/126) were males, and the mean age was 69.90±10.06 years old. Most of patients were diagnosed with multiple myeloma (84%, 53/63) and the remaining ones (16%, 10/63) were diagnosed with smoldering multiple myeloma. According to the ISS classification, 43% (27/63) of patients are in stage III. The data analysis revealed two associations of the studied gene polymorphisms with MG. First, the analysis by gender stratification suggested a decreased predisposition to MG in male carriers of NFKB2 rs12769316 GA and AA genotypes (OR 0.346, 95%CI 0.124–0.965, p=0.043). Second, we observed that patients with BIRC5 rs9904341 CC genotype had a highly significant lower overall survival (recessive model: HR 4.89, 95%CI 5.06 199.70, p<0.01). BIRC5 GGC haplotype (rs4789551, rs9904341, and rs8073069) was found in one patient and absent in controls.
Summary/Conclusions: The present study suggests that NFKB2 gene variant (rs12769316, allele A) may be associated with MG susceptibility in males, and BIRC5 (rs9904341) CC genotype may negatively influence MG prognosis. Nonetheless, further studies are needed to validate these findings, enlighten the role of genetic polymorphisms in MG susceptibility and prognosis.

PB1939

SILENCE OF LONG NONCODING RNA MALAT1 BY RNA INTERFERENCE INHIBITS PROLIFERATION AND INDUCES APOPTOSIS IN MULTIPLE MYELOMA

H. Liu[1,*], Z. Gong[1,2], W. Yang[1]
[1]Hematology, Shengjing Hospital of China Medical University, Shenyang, China, [2]Hematopathology, The University of Texas, MD Anderson Cancer Center, Houston, United States

Background: Multiple myeloma (MM) is a neoplastic plasma-cell disorder characterized by abnormal proliferation of monoclonal plasma cells in bone marrow leading to various end-organ damages. Altered long non-coding RNAs (lncRNAs) levels can result in aberrant expression of gene products that may contribute to cancer biology. Metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), an evolutionarily highly conserved mRNA-like lncRNA was originally identified with high expression in metastatic non-small-cell lung cancer and reported to be up-regulated in many other cancers. However, the function of *MALAT1* in MM remains unknown.
Aims: Our study aimed to evaluate the role of *MALAT1* on proliferation as well as apoptosis in MM cells *in vitro* and tumorigenic ability *in vivo*, following transfection with MALAT1-specific short hairpin RNA (shRNA) expression plasmids.
Methods: Levels of *MALAT1* in human myeloma cell lines were detected by real-time polymerase chain reaction (RT-PCR) analysis. The effects of *MALAT1* shRNA in MM were investigated *in vitro* and *in vivo*.
Results: We found that *MALAT1* was high expressing in RPMI8226 and U266 cells. Silencing of *MALAT1* by shRNA significantly inhibited the proliferation through cell cycle arrest at G1 phase and induced apoptosis, which was closely associated with activation of caspase-3/-9, downregulation of Bcl-2 and upregulation of Bax. Study *in vivo* revealed that silencing of *MALAT1* delayed the tumor growth and led to apoptosis in mice bearing myeloma xenograft.
Summary/Conclusions: *MALAT1* may serve as a promising novel therapeutic target in human MM. Notably, the inhibition of *MALAT1* by shRNA may prove to be an effective genetic therapeutic strategy for MM treatment.

PB1940

LONG NON-CODING RNA MEG3 FUNCTIONS AS A COMPETING ENDOGENOUS RNA TO REGULATE PTEN EXPRESSION BY SPONGING MIR-181A IN MULTIPLE MYELOMA

L. Chen[1,*], H. Bai[1], H. Zhu[1], X. Shen[1], J. Li[1], W. Yu[1]
[1]the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: Long non-coding RNA maternally expressed gene 3 (MEG3) plays a critical role in cancer progression and metastasis. However, the overall biological role and regulatory mechanism of MEG3 in multiple myeloma (MM) development and progression remains largely unknown.
Aims: To explore the tumor suppression role of lncRNA MEG3 in MM and further reveal the mechanism of MEG3 functions as ceRNA to contribute to MM pathogenesis.
Methods: MEG3 expression was measured in MM patients by real-time PCR.

The effect of MEG3 on cell apoptosis, cell proliferation and angiogenesis were gained from CCK-8, flow cytometric analysis and transwell invasion assays in MM cell lines ARP-1 and LP-1. Insights of the mechanism of competitive endogenous RNA (ceRNA) were gained from bioinformatic analysis, luciferase reporter assays and RNA binding protein immunoprecipitation (RIP) assay.
Results: MEG3 expression was significantly decreased in MM patients with advanced stage disease (ISS II and III) and poor prognosis.Overexpression of MEG3 promoted cell apoptosis and inhibited cell proliferation, migration and angiogenesis in MM ARP1 and LP-1 cell lines. Furthermore, MEG3 increase the expression of phosphatase and tensin homolog (PTEN) and consequentially inhibit MM cell proliferation and angiogenesis through sponging miR-181a *in vitro*. miR-181a mimics can limit the promotion of PTEN by MEG3.
Summary/Conclusions: MEG3 functions as a tumor suppressor in MM. High expression of MEG3 is a marker for good survival. We reveal a novel mechanism that MEG3 as a ceRNA of the PTEN gene by competing for miRNA-181a binding sites and thereby regulate the expression of the PTEN mRNA.

PB1941

IMPROVE RISK-STRATIFICATION OF MULTIPLE MYELOMA PATIENT WITH MICROFLUIDIC DEVICES

C. Li[1], L. Gao[1], Y. Zeng[1], X. Zhang[1], J. Zhong[1,*]
[1]University of Southern California, Los Angeles, United States

Background: Cytogenetic alterations are required for risk stratification of multiple myeloma (MM); however, current pathology assays performed on bone marrow samples directly can produce false negatives due to the unpredictable distribution and rarity of MM cells. A more accurate method is needed for MM diagnosis and risk-stratification. We develop a new microfluidic device to facilitate CD45-depletion for enhancing the detection of cytogenetic alterations in plasma cells.
Aims: Improve accuracy of risk stratification for multiple myeloma patients
Methods: Bone marrow samples from 48 MM patients were divided into two parts each. One part was directly detected by classic flow cytometry and FISH while the other part was first enriched by microfluidic size selection and then underwent CD45-cell depletion (MF-CD45-TACs). The enriched samples were then analyzed by flow cytometry and FISH and compared to the classical analysis.
Results: MF-CD45-TACs significantly increased the percentage of CD38+/CD138+ cells to 37.7%±20.4% (P<0.001) compared to 10.3%±8.5% in bone marrow. After the MF-CD45-TACs enrichment, the detection rate of IgH rearrangement, del(13q14), del(17p) and 1q21 gains rose to 56.3%(P<0.001), 37.5%(P<0.001), 22.9%(P<0.001) and 41.7% (P=0.001), respectively, all significant increases compared to untreated samples.
Summary/Conclusions: We have developed a rapid, simple assay for improved diagnostics and risk-stratification for MM. With more precise diagnosis, the clinical outcomes of MM will be significantly improved.

PB1942

SERUM FREE LIGHT CHAIN RATIO IS AN INDEPENDENT RISK FACTOR FOR PROGRESSION IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

R. Cherif[1,*], B. Salah Eddine[1]
[1]Hematology, Central Hospital Mohammed Seghir Nekkache, Algiers, Algeria, Algiers, Algeria

Background: Monoclonal gammopathy of undetermined significance (MGUS) is a premalignant plasma cell proliferative disorder found in approximately 3% of the general population 50 years of age and older. MGUS is associated with progression to multiple myeloma or related malignancy at a rate of 1% per year. Thus the risk of malignancy for a 50-year-old patient with a 25-year life span is 25%.
Aims: We hypothesized that the presence of monoclonal free kappa or lambda immunoglobulin light chains in monoclonal gammopathy of undetermined significance (MGUS), as detected by the serum free light chain (FLC) assay increases the risk of progression to malignancy.
Methods: 90 Patients seen at the Hematology consultation from 2010 to 2015 with MGUS have a serum Mprotein less than 30 g/L, bone marrow plasma cells less than 10%, and no anemia, hypercalcemia, lytic bone lesions, or renal failure that would be indicative of a malignant plasma cell disorder.
The prognostic effect of abnormal kappa-to-lambda FLC ratio on progression of MGUS was studied. We also examined whether the risk of progression varied depending on the extent to which the FLC ratio was abnormal (the normal reference range of κ/λ ratio 0.26 to 1.65).
Results: The median age at diagnosis of MGUS was 59 years (35-92years). 62 Womans and 28 Mans Sex ratio=2.2. Serum electrophoresis and immunoelectrophoresis or immunofixation was done in 85 patients. Of these, The median serum M protein size at diagnosis was 12 g/L (1.7-28.5g/L). IgG monoclonal : 68 patients (75%), and non IgG monoclonal : 22 patients (25%). A monoclonal light chain was detected in 62 patients, as detected by the serum free light chain (FLC) assay increases the risk of progression to malignancy. An abnormal FLC ratio (kappa-lambda ratio <0.26 or >1.65) was detected in 27 (30%) patients. At a median follow-up of 5 years, malignant progression had occurred in 6 patients (6,6%) with an abnormal serum FLC ratio.
Summary/Conclusions: A novel, highly sensitive serum free light chain (FLC) assay is now available for clinical practice.The risk of progression in patients with an abnormal FLC ratio was significantly higher compared with patients with a normal ratio, and was independent of the size and type of the serum monoclonal (M) protein. Patients with an abnormal serum FLC ratio, non–immunoglobulin G (non-IgG) MGUS, and a high serum M protein level (>15 g/L) had a major risk of progression.

PB1943

INTENSITY OF EXPRESSION OF MULTIDRUG RESISTANCE GENES AFFECT ON THE OVERALL SURVIVAL OF PATIENTS WITH MULTIPLE MYELOMA WERE TREATED WITH BORTEZOMIB AND ASSOCIATED WITH THE INITIAL MULTIDRUG RESISTANCE

Y. Chernykh[1,*], A. Golenkov[1], L. Vysotskaya[1], K. Belousov[1]
[1]clinical haematology, Moscow Regional Research and Clinical Institute, Moscow, Russian Federation

Background: Bortezomib is an important drug in multiple myeloma (MM) treatment, but the resistance to this treatment exist. Many conflicting data suggests that cellular overexpression of multidrug resistance (MDR) genes may reduce the effectiveness of bortezomib - containing treatment. The main indicator of the effectiveness of the treatment of MM is the overall survival of patients.
Aims: We evaluated the changes of intensity of expression of MDR genes in patients with newly diagnosed and refractory/relapsed multiple myeloma and the effect of expression of MDR genes such as MDR 1, MRP 1, BCRP, LRP on the overall survival of patients after treatment with bortezomib.
Methods: The bone marrow aspirates of 30 patients (12 men and 18 women) aged 48 to 77 years (median 60 years) with stage III MM by classification Durie-Salmon were studied. 15 patients were included in a group of newly diagnosed (ND) MM. 15 patients were in group of a clinically refractory/ relapsed (RR) MM. The bone marrow in this group of patients were studied after treatment with alkylating agents at the time of registration of resistance to the given therapy. In the future, all patients were treated by bortezomib - containing chemotherapy regimens. mRNA expression studied genes were determined by semi-quantitative polymerase chain reaction reverse transcription. The degree of expression was assessed by semi-quantitative visual assessment from 0 (no electrophoretic strips) to 4 points (bright glow of the transcript). The overall survival (OS) was analyzed by the Kaplan-Meier method, with the use of Cox-Mantel test. Differences were considered statistically significant at p <0.05.
Results: In both groups of patients had comparable expression of all studied MDR`s genes. The development of clinical resistance to treatment with alkylating agents were accompanied by an increase in mRNA expression of all studied genes. However, the statistically significant increase the expression of the intensity obtained for LRP gene only (the average intensity of the expression of mRNA LRP gene in ND MM 0.9±0.24, with RR MM 1.93±0.34, p <0.05). The MDR 1 mRNA expression was 1.50±0.34 in the group of ND MM and 1.67±0.31 in the group of RR MM, p>0.05. The expression of mRNA of MRP 1 and BCRP are 1.07±0.21 and 1.63±0.15 respectively before treatment and increased to 1.73±0.31 and 2.13±0.35 respectively in the group of RR MM, p=0,06. OS was negatively associated with high LRP gene expression only in group of ND MM (median of OS in patients with high LRP gene expression was 17 months and in those with low expression 62 months, p <0.05).
Summary/Conclusions: High expression of LRP gene is associated with worse overall survival in patients with newly diagnosed MM treated with bortezomib- containing chemotherapy programs. “Genetic resource MDR” in MM is due mainly to the initial multidrug resistance. The treatment of MM by alkylating drugs increase the existing at the time of diagnosis of MDR activity of genes.

PB1944

ASSOCIATIONS OF IL-1, IL-4 AND TGF-B1 POLYMORPHISMS WITH CYTOGENETIC PROFILES IN PATIENTS WITH MULTIPLE MYELOMA

A. Pavlova[1,*], I. Pavlova[1], L. Bubnova[1], S. Bessmeltsev[2], E. Kleina[3], A. Garifullin[4], I. Martynkevich[3], S. Voloshin[2], A. Chechetkin[2]
[1]Immunohaematology laboratory, [2]Russian Institute of Haematology and Transfusion, Saint-Petersburg, Russian Federation, [3]Laboratory of molecular genetics, [4]Haematology clinic, Russian Institute of Haematology and Transfusion, Saint-Petersburg, Russian Federation

Background: Multiple myeloma (MM) is a plasma cell malignancy characterized by complex cytogenetic and molecular genetic aberrations. Those cytogenetic abnormalities occur at different stages of the disease. The chromosome ploidy status and Ig rearrangements are two genetic criteria that are used to help stratify patients into prognostic groups.
Aims: The aim of the study was to analyse correlation between cytogenetic profiles and some cytokine genotypes in 24 patients with MM (Caucasoid inhabitants of the North-West region of Russia).
Methods: Genomic DNA was extracted from the peripheral blood; gene geno-

typing (IL-4, TGF-β1, IL-1α, IL-1β) was performed by PCR-SSP; study of cytogenetic abnormalities was performed by standard GTG-method and interphase FISH analyses with DNA probes: LSI 13(RB1)13q14, IGH/CCND1, IGH/FGFR3, LSI TP53 (17q13.1); p-values less than 0.05 were considered statistically significant.
Results: Previous results allow us to describe some cytokine genotype markers associated with the development of MM (IL-1α -889 TT, IL-1β +3962 TT, IL-6 -174 GG and IL-6 nt565 GG; gr. 1) as additional negative prognostic markers but IL-4 -33 CC and TGF-β1 codon 25 GG genotypes as additional positive prognostic markers (gr. 2). However, in some MM patients we found presence of negative and positive markers together (mixed markers; gr. 3). We analyzed cytogenetic profiles in MM patients with different prognostic markers in their genotypes (Table 1).

Table 1.

Genotypes with prognostic markers	Abnormal cytogenetic profile	Normal cytogenetic profile
1st gr. - MM patients with negative prognostic markers in genotype: IL-1a -889TT, IL-1b +3962TT, IL-6 -174GG, IL-6 nt565GG	0.778*	0.222
2nd gr. - MM patients with positive prognostic markers in genotype: IL-4 -33CC, TGF-b1 codon25GG	0.111*	0.889*
3rd gr. - MM patients with mixed prognostic markers in genotype	0.667	0.333
*- p<0.05		

The frequency of abnormal cytogenetic transformations in the 2nd gr. was noticeably lower compare to patients from the 1st and 3rd gr. (0.11 *vs* 0.78 *vs* 0.67 respectively; p<0.05). Similarly, significant differencies in the frequency between patients with positive prognostic markers and normal cytogeneic profile (0.89) compare to MM patients with negative (0.22) or mixed (0.33) genotypes but normal cytogenetic profiles were also observed (p<0.05). In the 1st gr. frequency of cytogenetic abnormalities was noticeably higher compare to patients with normal profile (0.78 *vs* 0.22; p<0.05). Vice versa, in patients with positive prognostic markers in the genotype frequency of normal cytogenetic profiles was remarkably higher (0.89) compare to patients with aberrations (0.11; p<0.05).
Summary/Conclusions: Thus, our results allow to describe IL-1α -889 TT, IL-1β +3962 TT, IL-6 -174 GG and IL-6 nt565 GG as markers associated with the presence of cytogenetic abnormalities in MM patient cells. However, IL-4 -33 CC and TGF-β1 codon 25 GG indicate the normal cytogenetic profile in patients with MM from the North-West region of Russia. Although, if MM patients have both negative and positive prognostic markers associated with the development of multiple myeloma (mixed genotype) it seems that the chance of finding cytogenetic abnormalities is much higher compare to patients with positive prognostic markers only.

PB1945

CORRELATION DEPENDENCE OF CHRONIC LYMPHOPROLIFERATIVE DISORDERS, MULTIPLE MYELOMA FROM CHANGES OF IMMUNE RESPONSE GENES PROFILE

E. Nazarova[1,*], V. Shardakov[1], A. Nagovitsina[1], E. Zotina[2], I. Dokshina[2]
[1]Laboratory of Immunology of Leukemia, [2]Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: Hematological malignancies are multifactorial diseases in the development of which play a role as environmental factors and genetic determination of leukemic process. Such genetic factors include the presence in human genome of allelic variants of the regulatory regions of the innate immune response genes. At present time, they are considered as real risk factors for these diseases in a person with a certain set of genetic variants. Their distribution among the population corresponds to the population laws and has its ethnographic features. Analysis of the individual associations of genes polymorphic variants involved in the implementation of the immune response does not sufficiently complete answer about their role in the formation of predisposition to the development of chronic lymphoproliferative disorders (CLD) and multiple myeloma (MM). It is noted that in the pathogenesis of hematological diseases contribute significantly to certain combinations of immune response genes.
Aims: Analysis of interactions between genes based on the distribution of immune response genes combinations in chronic lymphoproliferative disorders and multiple myeloma.
Methods: The study included 176 patients aged 22-86 years (median - 61 year), identifying themselves as Caucasians residing in one region in the north-east of the Russian Federation. This group consisted of 80 patients with chronic lymphocytic leukemia/small lymphocytic lymphoma (45%), 72 with multiple myeloma (41%), 10 with diffuse large B-cell lymphoma (6%) six with marginal zone lymphoma (3%) four with mantle cell lymphoma (2%), three with lymphoplasmacytic lymphoma (2%) and one patient with follicular lymphoma (1%). Genotyping of polymorphism of the innate immune response genes *TLR2* (rs5743708), *TLR3* (rs3775291), *TLR6* (rs5743810), *TLR9* (rs5743836), *IL1β* (rs2856841), *IL2* (rs2069762), *IL4* (rs2243250), *IL6* (rs1800795), *IL10* (rs1800871), *IL17A* (rs2275913), *CD14* (rs34424920), *TNFα* (rs1800629), *FCGR2A* (rs1801274) was performed by polymerase chain reaction with allele-specific primers (Litech, Russia). Analysis of interactions between genes was performed using nonparametric GMDR program (Generalized Multifactor-Dimensionality Reduction) [Lou X.Y. *et al.*, 2007.; http://www.healthsystem.virginia.edu/internet/addiction-genomics/Software/].
Results: In the analyzed group of patients with CLD and MM identified almost 78 753 combinations of multi-locus genotypes of the 13 immune response genes is 1 594 323 theoretically possible, indicating the non-random nature of the combination of allelic variants of analyzed genes. A statistically significant two-, three-, four-, five-, six, seven- and eight-loci model of inter-gene interactions at the investigated hematological malignancies: - *IL4* (C-589T) and *CD14* (C-159T) (χ^2=8.39, p=0.0038); - *IL4* (C-589T) and *CD14* (C-159T) and *IL6* (C-174G) (χ^2=12.14, p=0.0005); - *IL4* (C-589T) and *IL17A* (G-197A) and *CD14* (C-159T) and *IL6* (C-174G) (χ^2=17.30, p<0.0001); - *IL4* (C-589T) and *IL17A* (G-197A) and *IL10* (C-819T) and *CD14* (C-159T) and *IL6* (C-174G) (χ^2=16.98, p<0.0001); - *IL4* (C-589T) and *IL17A* (G-197A) and *IL10* (C-819T) and *TNF* (C-308A) and *CD14* (C-159T) and *IL2* (T-330G) (χ^2=16.98, p<0.0001); - *IL4* (C-589T) and *IL17A* (G-197A) and *IL10* (C-819T) and *TNF* (C-308A) and *TLR9* (T-1237C) and *CD14* (C-159T) and *IL2* (T-330G) (χ^2=16.98, p<0.0001); - *IL4* (C-589T) and *IL17A* (G-197A) and *IL10* (C-819T) and *TNF* (C-308A) and *TLR9* (T-1237C) and *CD14* (C-159T) and *IL2* (T-330G) and *IL1b* (T-31C) (χ^2=16.98, p<0.0001); - *IL4* (C-589T) and *IL17A* (G-197A) and *IL10* (C-819T) and *TNF* (C-308A) and *TLR9* (T-1237C) and *CD14* (C-159T) and *IL2* (T-330G) and *IL1b* (T-31C) and *TLR2* (Arg753Gln) (χ^2=16.98, p<0.0001).
Summary/Conclusions: The findings suggest an important role of immune response genes in the development of a number of chronic lymphoproliferative disorders and multiple myeloma, and can later be used as diagnostic and prognostic markers of different types of hematological malignancies. In addition, provided bioinformatics model will reveal not only the genetic criteria for high and low risk of hematological malignancies studied, but also to determine their prognostic significance in the clinical course of these diseases.

PB1946

FEATURES OF STROMAL ELEMENTS OF HEMATOPOIETIC BONE MARROW NICHE IN MULTIPLE MYELOMA

N.Y. Semenova[1,*], S. Bessmeltsev[1], V. Rugal[1]
[1]Russian research institute hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: Structure of bone marrow stroma – mesenchymal stromal cells (MSC), endosteal stromal cells, and microvessels forming the hematopoietic niche and regulate the development of hematopoietic stem cells (HSC). Analysis of morphological changes of these elements of the hematopoietic niche is important to clarify the pathogenesis of multiple myeloma (MM).
Aims: To investigate the morphological and functional characteristics of stromal elements of the hematopoietic niche in bone marrow of patients with MM, as well as the characteristics of culture of mesenchymal stromal cells (MSC) and hematopoietic stem cells (HSC).
Methods: 42 trepanobiopsy of bone marrow from patients diagnosed with MM were used for the study. The age of the patients ranged from 53 to 72. The study applied histological, histochemical, immunohistochemical (IHC) and morphometric methods (VideoTest®). Also 20 patients from this group conducted cultural studies for the determination of colony-forming ability of HSC and morphofunctional status of MSC.
Results: Myeloma cellular composition of infiltrates were polymorphic. The surveyed patients were allocated to 3 types of infiltration is nodular, interstitial, diffuse. The histogenesis of infiltration was confirmed by IHC research with antibodies 79α, CD 138, CD 38.Regardless of the type of infiltration in all patients were recorded focal destructive changes of bone tissue. The density of microvessels in IHC studies with antibodies to CD 31, CD34 cl.II (Dako) was increased. A greater number of microvessels were detected in the endosteal area at all types of the bone marrow involvement (compared to normal), the total number of microvessels could statistically do not exceed such normal. A reduction in the expression of type I collagen bone matrix and the increase of collagen type IV expression, which is associated with increased microvascular density. Intratrabecular collagen type I was mellowed, ossification was reduced, most notably it revealed in areas of trabecules resorption. At the same time increased the amount of collagen type IV in endosteal spaces of the bone marrow. A typical feature was the appearance of focal network of reticulin fiber in subendosteal and perivascular spaces.Cultural studies have shown a significant decrease of colony-forming ability of HSC mobilized peripheral blood of MM patients after cryopreservation. *In vitro* studies preliminary data on lack of differences in the phenotype of MSC bone marrow of patients with MM and phenotype from healthy individuals, but also, a decrease in the proliferative ability of the MSC of patients with MM.
Summary/Conclusions: Analysis of parenchymal-stromal relationships in trepanobiopsy bone marrow of patients with MM evidence of their violation in the context of malignancy of lymphopoiesis, while cultural studies have shown a decrease of colony-forming ability of HSC and proliferative capacity of MSC. Regardless of the prevalence of neoplastic lesions, and myeloma infiltration noted the response of the stromal microenvironment, forming the hematopoietic niche.

IMPACT OF RENAL IMPAIRMENT IN NEWLY DIAGNOSED MULTIPLE MYELOMA IN A REAL WORLD SETTING

V. Bove[1,*], F. Villano[1], L. Díaz[1], E. Riva[1]
[1]Hematología, Hospital de Clínicas, Montevideo, Uruguay

Background: Renal impairment (RI) is a frequent complication of patients with newly diagnosed multiple myeloma (NDMM), reported in 15-40% with 10% requiring hemodialysis (HD). It is associated with higher early mortality (EM) and lower overall survival (OS). Early diagnosis and treatment with new agents improve these results.
Aims: Analyze renal response, OS and EM in NDMM with RI and compare them to patients with MM without RI.
Methods: All consecutive and unselected NDMM patients treated at Hospital de Clínicas, Montevideo, Uruguay, from January 2011 to June 2015 were included. Our database was completed prospectively and included clinical and laboratory characteristics of the disease, treatment, treatment-related adverse events, response, HD requirement, renal response and mortality.
Diagnosis of MM, response to treatment and degree of renal function recovery were based on the International Myeloma Working Group criteria. RI was defined as an estimated glomerular filtration rate (eGFR) <40 ml/min/1.73m^2, calculated by MDRD (*Modification of Diet in Renal Disease*) equation. Patients whose RI was explained by other causes were excluded. Early treatment was defined by initiation within 7 days after diagnosis. EM was defined as death within 3 months of diagnosis.
Results: MM was diagnosed in 52 patients, median age was 67 years (range 39-90), 61,5% were male, 38,5% had RI. The characteristics of the patients and front-line treatment are shown in Figure 1.

Characteristics (mean)		Pts with RI (n=20)	Pts without RI (n=32)
Age (years) median		68,5 (49-90)	63 (39-85)
Male		12 (60%)	20 (62,5%)
eGFTR (ml/min/1,73m^2)		19,3	72,7
Hemoglobin (g/dl)		7,8	9,7
Calcium (mg/dl)		10,2	9,5
Serum M Spike (mg/dl)		3,4	2,8
Urinaria Proteins (g/24hs)		1,4	0,04
M-component type:	IgG, IgA, IgM	17 (85%)	27 (84,4%)
	Light chain	3 (15%)	2 (6,2%)
	No secretor	0	3 (9,4%)
Light chain type:	Kappa	10 (50%)	19 (59,4%)
	Lambda	10 (50%)	10 (31,2%)
Stage III Durie-Salmon		19 (95%)	26 (81,3%)
ISS 3		18 (90%)	9 (28,1%)
Treatment:	Steroids	20 (100%)	32 (100%)
	Thalidomide	5 (25%)	22 (68,8%)
	Bortezomib	11 (55%)	5 (15,6%)

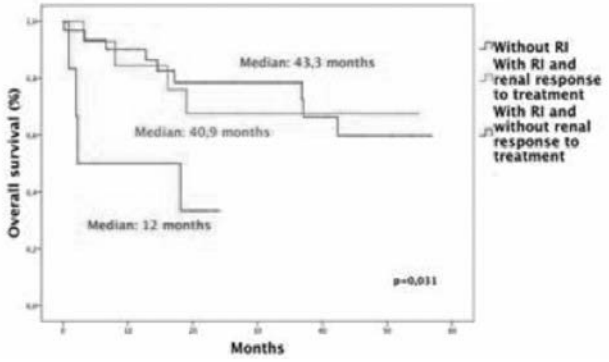

Figure 1. Characteristics of patients and overall survival according to renal function.

Overall response to first line treatment was 70% for those with RI (CR 20%) and 68,8% in patients without RI (CR 15,4%). Treatment related adverse effects were higher in patients with RI (45% *vs* 28,2%), being polyneuropathy the most common side effect. Patients with RI required more dose adjustments (40% *vs* 6,3%). Renal response: 50% reversed RI, 10% achieved renal PR and 40% renal CR, all before the 4th month from diagnosis; 77,8% started early treatment and 70% received bortezomib (bz). Patients whose RI did not reverse had had late initiation of treatment in 78% and 40% received bz. Six patients (30%) remained in chronic HD, all had late initiation of treatment. Two of the 6 patients who required HD at diagnosis obtained later independence; both received bz and one was consolidated with autologous stem cell transplantation. Impact of RI on OS and EM: median OS in patients with RI was not significatively different to that of MM without RI (35,3 *vs* 43,3 months, p=0,346). Patients without RI had higher OS compared to those who had reversible renal failure and those who never recovered (43,3; 40,9 and 12 months, respectively, p=0,031). OS was higher in patients with RI who received bz *vs* other therapeutic schemes (42,5 *vs* 25,8 months, p=0,137). With a mean follow-up of 26 months, mortality was 40% and 28,1% in patients with and without RI, respectively. EM were also higher in patients with RI at diagnosis (50% *vs* 22,5%). The main cause of EM was infection in both groups.
Summary/Conclusions: RI was frequent in NDMM and was associated with advanced disease and higher tumor mass (>90% stage III Durie-Salmon and ISS3), revealing a late diagnosis. Prompt institution of treatment and use of bz relates to higher recovery of renal function and dyalisis independence. Although toxicity and dose adjustements were higher in patients with RI this was not associated with lower response to treatment. Reversal of renal failure associates with better OS, similar to those without RI at diagnosis. EM are more prevalent in patients with RI at diagnosis. Even when the number of patients is small, this real life data supports the need of planning local strategies that lead to early diagnosis and initiation of treatment, which are crucial to reduce morbidity and mortality associated to RI in NDMM.

THE EXPRESSION OF THE TRYPTASE POSITIVE MAST CELLS AND THE LEVELS OF IL-17, CORRELATE WITH ANGIOGENIC FACTORS IN PATIENTS WITH MULTIPLE MYELOMA

M. Kokonozaki[1], C. Pappa[2], R. Vyzoukaki[1], A. Stavroulaki[3,*], M. Devetzoglou[4], A. Papadopoulou[1], I. Liapis[4], A. Boula[3], M. Alexandrakis[5]
[1]Laboratory of Haematology, University Hospital of Heraklion, [2]Department of Internal Medicine, [3]Department of Haematology, Venizelion Hospital, [4]Department of Haematology, University Hospital of Heraklion, [5]Medical School, University of Crete, Heraklion, Greece

Background: Angiogenesis in the bone marrow plays a very important role in the progression of multiple myeloma(MM). The procedure of angiogenesis is supported by several factors such as VEGF, FGF-2 and metalloproteases that are secreted straight from the tumor cells. The presence of IL-6 in the microenvironment, induces the production and the secretion of several angiogenic factors that activate inflammatory cells of the matrix, like macrophages and mast cells to secrete more angiogenic factors. IL-17 is among the most important cytokines that have an important role in the development of myeloma tumor. IL-17 is a proinflammatory cytokine that is secreted primarily by CD4 (activated memory cells) and stimulate macrophages, fibroblasts and other cells that release several cytokines. It has been reported that IL-17, induces angiogenesis in humans by stimulating the migration of vessel endothelial cells and adjusting the production of various proangiogenic factors. In a previous study, it was found that increased levels in stage II and stage III, resolved after therapy. Additionally, blocking the receptor of IL-17, with an antibody, cancels the effects of IL-17.
Aims: Aim of this study is to assess the relationship of the MCD and IL-17, in angiogenesis of MM, as well as their correlation with known angiogenic factors in disease progression.
Methods: We studied 52 newly diagnosed patients with MM, 32 women and 20 men, aged 67,5±9,6 years. According to the ISS stage, 19 were stage I, 17 stage II and 16 stage III . Regarding the type of paraprotein that had been found, 31 IgG, 17 IgA and 4 patients with light chains. 20 age and sex-matched healthy volunteers, were used as controls. Serum samples and bone marrow biopsy samples were obtained from all patients prior to the initiation of treatment. Patients with impaired hepatic and renal function, chronic or acute infections, chronic inflammatory or autoimmune disorders or other malignancies were excluded from the study.We also excluded patients who were taking anti-inflammatory drugs, corticosteroids or bisphosphonates. IL-17, bFGF and ANGIOP-2 were measured in patients' serum with ELISA method according to the manufacturer's instructions. The MCD assessed after immunohistochemical staining using monoclonal antibody to mast cell tryptase. The MCD was measured in three hot spots (maximum vasculature area) x 100 and then we measured mast cells x 400, using a graduated slide which corresponds to an area of 0.0625 mm2. MCD was calculated as mean MCD / HPF.
Results: Statistically significant differences between patients and controls were observed in all measured parameters, MCD (p <0.001), bFGF (p <0.01) and ANGIOP-2 (p <0.01), and for IL-17 (p <0.04). All parameters were increased in parallel with ISS stages (p <0.001) in all cases. Finally, the MCD and IL-17 correlated significantly with all the measured parameters (p <0.001)
Summary/Conclusions: The mast cells increase in the bone marrow(BM) of patients with MM. They release several transmitters that promote directly and indirectly the development of disease progress of MM also accompanied by increased angiogenesis in BM. In conclusion, mast cells and angiogenic factors seem to be important elements in the development of MM and become potential targets for the treatment and prognosis of the disease.

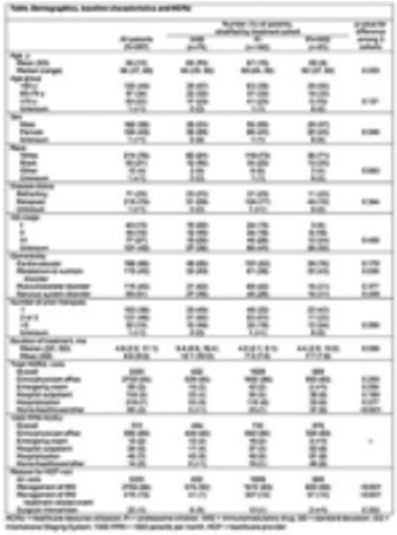
PB1951

HEALTHCARE RESOURCE UTILIZATION ASSOCIATED WITH DIFFERENT TREATMENT MODALITIES OF RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS IN THE US: FINDINGS FROM PREAMBLE

D. Kuter[1], C. Chen[2,*], S. Khare[3], S. Perez[4], T. Zyczynski[2], C. Davis[2], R. Vij[5]
[1]Massachusetts General Hospital, Boston, [2]Bristol-Myers Squibb, Lawrenceville, United States, [3]Mu Sigma, Kamataka, India, [4]Mu Sigma, Northbrook, [5]Washington University School of Medicine, St. Louis, United States

Background: Proteasome inhibitors (PIs), immunomodulatory drugs (IMiDs) and treatments involving both a PI and an IMiD (PI+IMiD) are the principal therapies for treating relapsed/refractory multiple myeloma (RRMM). The widespread adoption of these treatments may come with high healthcare resource utilization (HCRU), of which key drivers are reported in past research. It is important to further understand HCRU by different treatment modalities in real-world practice settings.
Aims: To evaluate HCRU in patients receiving different treatment modalities for RRMM.
Methods: US patients with RRMM, aged ≥18 y, with at least one prior therapy who initiated treatment with a PI, IMiD or IMiD+PI within 90 d before or 30 d after study enrollment (index therapy), were identified from PREAMBLE, an ongoing, prospective, multinational, non-interventional observational study. Patient data collected at each healthcare provider (HCP) visit, over a 3-y period or until the end of patient follow-up, included clinic/physician office visits; home healthcare, hospital outpatient and emergency room visits; and hospitalizations. Demographics and baseline characteristics were summarized using descriptive statistics. HCRU and its associated costs were analyzed using a standard per-1000 patients-per-month metric.
Results: 287 patients (median age 66 y; 56% male) were enrolled in the US. At the time of data cut-off (Sep 2016), 136 (47%) were still in the study and 151 (53%) had withdrawn; 92 (61%) of those withdrawn had died. Median (range) follow-up was 12.7 (0.5–41.0) mo. At study entry, patients were divided into three cohorts based on index therapy: PI (n=162, 56%; carfilzomib n=82/162; bortezomib n=80/162), IMiD (n=74, 26%; pomalidomide n=32/74; lenalidomide/thalidomide n=42/74), and PI+IMiD (n=51, 18%; carfilzomib and/or pomalidomide n=17/51; other n=34/51). The three groups were similar with regard to sex, race, disease status, ISS stage, comorbidities and number of prior therapies (Table 1).

Table 1.



The median duration of treatment (mDoT) was longer for patients on IMiD (6.4 mo), but shorter for those on PI (4.2 mo) or PI+IMiD (4.4 mo). In the PI cohort, carfilzomib had a shorter mDoT than bortezomib (3.5 *vs* 4.7 mo). Of 3220 total HCP visits, the most common type was clinic/physician office (2732, 85%), followed by hospitalization (210, 7%) and hospital outpatient (54, 5%). Mean per-1000 patients-per-month total visits were higher for PI+IMiD (876) than for PI (750) and IMiD (494). This remained true for clinic/physician office, hospital outpatient and home healthcare/other. Patients on PI had more visits for management of MM treatment-related events (16%) than those on PI+IMiD (10%) or IMiD (7%) (Table 1). Notably, among patients on PI, those on carfilzomib had high mean per-1000 patients-per-month total visits (827), with per-1000 patients-per-month emergency room visits (18) and hospitalizations (78) higher than any other treatment; 19% (175) of visits were made for management of treatment-related events.
Summary/Conclusions: Routine management of MM and treatment-related events drive HCRU, which may differ by treatment. Hospitalizations and hospital outpatient visits remain key drivers of HCRU in MM, which highlights an unmet medical need for effective therapy with better safety profiles.

PB1952

ASSOCIATION OF SERUM HEAVY/LIGHT CHAIN PAIR SUPPRESSION WITH RISK FACTORS FOR PROGRESSION IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND SMOLDERING MYELOMA

I. Isola[1,*], M.T. Sanz[2], M.T. Cibeira[1], L. Rosiñol[1], E. Lozano[1], J.I. Aróstegui[3], M. Elena[4], N. Tovar[1], J. Yagüe[3], E. Moga[2], J. Bladé[1], C. Fernández de Larrea[1]
[1]Hematology (Amyloidosis and Myeloma Unit), Hospital Clínic de Barcelona, [2]Immunology, Hospital de la Santa Creu I Sant Pau, [3]Immunology (Amyloidosis and Myeloma Unit), [4]Biochemistry (Amyloidosis and Myeloma Unit), Hospital Clínic de Barcelona, Barcelona, Spain

Background: Monoclonal gammopathy of undetermined significance (MGUS) and smoldering multiple myeloma (SMM) are conditions that usually precede symptomatic multiple myeloma (MM). Risk stratification is crucial, considering the heterogeneous progression rate among these patients and the chemoprevention trials encouraged for high risk individuals. A number of prognostic factors for progression have been identified. In this sense, the novel Hevylite assay now enables us to accurately measure each isotype-specific heavy and light chain (HLC). Recently, isotype-specific uninvolved HLC pair suppression was described as an independent predictor of progression to MM in patients with MGUS. The role of Hevylite as a prognostic factor in SMM is less investigated.
Aims: The aim of the present study was to analyze the impact of HLC pairs in a series of patients with high risk MGUS and SMM and their relationship with other previously described risk factors.
Methods: Forty-four patients diagnosed with high risk MGUS or SMM at a single institution from March 2014 through April 2016 were prospectively included in the present study. Patients were stratified according to the Mayo Clinic and the Spanish PETHEMA group models. Samples at diagnosis were tested for HLC concentrations for the three pairs (IgG, IgM and IgA) by immunonephelometry.
Results: The clinical characteristics and risk stratification of patients are summarized in Table 1.

Table 1. Patient characteristics and risk stratification.

	All patients *N*= 44	MGUS *N*=26	SMM *N*=18
Median age, years (range)	69 (42-88)	69 (42-88)	68 (45-82)
Female gender, *N* (%)	21 (48)	12 (46)	9 (50)
HLC isotype, *N* (%)			
IgGκ	7 (16)	4 (15)	3 (16)
IgGλ	6 (13)	1 (4)	5 (28)
IgAκ	10 (23)	5 (19)	5 (28)
IgAλ	10 (23)	5 (19)	5 (28)
IgMκ	10 (23)	10 (38)	0
IgMλ	1 (2)	1 (4)	0
Serum M- protein, g/L; median (range)	15.2 (0-32.8)	14.1 (0-24.5)	23.9 (10.6-32.8)
Bone marrow plasma cell (%), median (range)	8 (1-97)	4.5 (1-9)	16.5 (10-97)
Proportion of normal plasma cell (%), median (range)	16 (0-100)	38 (0-100)	7.5 (0-88)
Presence of urine light-chain, *N* (%)	25 (58)	14 (56)	11 (61)

Mayo Clinic risk group (SMM)**			
1			7 (39)
2			8 (44)
3			3 (17)
Spanish PETHEMA risk group (SMM)***			
0			7 (39)
1			2 (11)
2			7 (39)

Risk factors for stratification: (*) serum M-spike > 15 g/L, non IgG isotype, serum free light-chain ratio <0.26->1.65); (**) serum M-spike ≥ 30 g/L, bone marrow plasma cells ≥ 10%, serum free light-chain ratio <0.125->8; (***) ≥95% abnormal bone marrow plasma cells, immunoparesis

An abnormal HLC-pair ratio was detected in 96% of MGUS and 94% of SMM patients, with no differences depending on the heavy chain isotype. A highly abnormal HLC ratio (<0.02 or >45) was present in 9 patients (1 with MGUS and 8 with SMM). HLC-pair suppression (*i.e.*, IgG-κ in patients with IgG-λ gammopathy) was more frequent in patients with SMM (83% *vs* 46%, p=0.02). Severe HLC-pair suppression (>50% below lower level of normal) was present in 12 (27%) patients, the majority of which had a diagnosis of SMM (83%). Severe HLC-pair suppression was significantly associated with a highly abnormal (<0.125 or >8) serum free light chain (FLC) ratio (p=0.004), abnormal/normal bone marrow plasma cell ratio >0.95 (p<0.001) and immunoparesis (p=0.005), being present in 6 (86%) of the 7 patients with high risk SMM. Suppression of the other isotypes (*i.e.*, IgA or IgM HLC pairs in a patient with IgG gammopathy) was identified in 33 (75%) patients, namely in 18 (69%) patients with MGUS and 15 (83%) patients with SMM (p=0.48), and was not significantly

associated with other risk factors for progression. Severe suppression (>50% below lower level of normal) was significantly more frequent in SMM patients (33% *vs* 8%, p=0.04) and was associated with highly abnormal FLC ratio (p=0.001), abnormal/normal plasma cell ratio >0.95 (p<0.001), severe HLC-pair suppression (p<0.001) and highly abnormal HLC ratio at diagnosis (p=0.005). The "evolving" pattern of the serum M-protein was identified in 12 patients (MGUS 7, SMM 5) and it was not significantly associated with either severe suppression of the HLC-pair or of the other isotypes. After a median follow-up of 18 months (range, 6-35) progression to symptomatic MM was observed in 3 patients. All 3 had a diagnosis of SMM with an "evolving" pattern, highly abnormal HLC-ratio and severe HLC-pair suppression.
Summary/Conclusions: The findings presented in this study indicate that highly abnormal HLC ratio, severe suppression of the HLC-matched pair and other isotype HLC pairs are associated with known risk factors for disease progression in patients with high risk MGUS and SMM. The HLC assay could become a valuable tool in the risk stratification of these patients.

PB1953

EXTRAMEDULLARY MYELOMA IN THE "NOVEL AGENTS ERA": OUTCOME, HETEROGENEITIES AND PECULIARITIES OF A COHORT OF 84 PATIENTS RETROSPECTIVELY ANALYSED IN A MONOCENTRIC EXPERIENCE

L. Torti[1,*], A. Morelli[1], F. Bacci[2], P. Di Bartolomeo[1]
[1]Department of Hematology and Bone Marrow Unit , Pescara, [2]Section of Hematopathology, Department of Hematology and Oncological Sciences, S. Orsola-Malpighi Hospital, Bologna, Italy

Background: Extramedullary disease is an uncommon manifestation in multiple myeloma (MM) and can either accompany newly diagnosed disease or develop with disease progression or relapse. Extramedullary myeloma (EMM) seems to have a different pathogenesis from its much more frequently encountered medullary counterpart, showing often a poor prognosis. EMM clinical situations are extraordinarily heterogeneous and their management is challenging.This includes organ or tissue involvement resulting from hematogenous-spread and/or bone involvement originating from different kind of bones.
Aims: We evaluated the impact of this disease features on patients' outcome in the context of novel-agents.
Methods: We reviewed 84 patients presenting EMM (median age 60, range 30-76)describing clinical and biological features (Figure 1B. Our aim was studying prognosis of bone-related extramedullary-disease (bEMD) and its relationship with soft-tissue related EMD (sEMD) in MM patients in our institution.
Results: 42 bEMD and 42 sEMD patients treated at Our Department between 2007 and 2016 were included in this study. Of the first group 10 presented EMM at diagnosis and 32 at relapse as well as 7 and 35 respectevely of the second series. 31 among sEMD were dead and 11 were alive, 20 of bEMD patients were dead and 22 were still alive. EM was diagnosed using imaging techiniques such as PET-CT (35%) or magnetic resonance MRI (65%). Biopsies were carried out only if the lesion was accessible (62%). The treatment was heterogeneous and all patients had receveid either thalidomide or bortezomib in the first-line of therapy. We showed that sEMD cohort has a significantly poorer survival compared to bEMD patients (median OS from diagnosis of EMD of 13 *versus* 58 months, P<0001). Finally lung, liver (parenchyma-EM) and SNC involvement among sEMD patients has shown a poorer outcome when compared to skin and lymph nodes masses respectively median OS of 12 and 10 months *versus* 18 and 15 months P <0001). Conversely among bEMD group there wasn't a significant advantage of outcome regarding the different bones involved. Kaplan-Meier estimates were used for survival analysis and differences between survival-times in patient subgroups were tested using the log-rank test (Figure 1A). Interestingly extramedullary-spread can be triggered by an invasive-procedures (surgery) or by a bone-fracture.In our population we have a case of breast-plasmocytoma diagnosed accidentally after reconstructive breast-surgery,where Polymerase Chain Reaction of immunoglobulin gene-rearrangement in the breast tissue excised confirmed monoclonal-CD 138/lambda plasma-cells. This patients at first was treated with VTD-regimen followed by tandem-ASCT and after EM-relapse achieved complete remission with haploidentical-bone-marrow-transplantation. Allogeneic transplantation should however be remembered in the therapeutic-armamentarium against EM especially in high-risk-young-patients. Furthemore often it has been described in the literature association between EMD, IgD subtype and FLC (free light chain)escape. In fact in our study we have reviewed 6 cases of IgD and 4 FLC-escape, all of them were observed in relapse-setting and in sEMD group. Finally the mechanism of extramedullary spread are poorly established: maybe a decrease expression of integrins and CD56 is involved. In our population absence of CD56 protein was shown in 56% of sEMD group and in 15%of bEMD case-series.
Summary/Conclusions: Cinical features of MM-patients with bEMD were different from the patients with sEMD. Outcome of this population was significantly better than the patients with sEMD, and was comparable to the patients without EMD. Even in the era of novel drugs extramedullary soft tissue has a poor prognosis expecially in a relapse-setting. This work shows a significant difference in prognosis for different type of extramedullary-disease even between sEMD (better OS of skin and lymph nodes involvement) suggesting a different biological-behavior.

PB1954

DINAMIC PREDICTIVE FACTORS FOR A BETTER STRATIFICATION OF PATIENTS WITH R-ISS II NEWLY DIAGNOSED MULTIPLE MYELOMA

M. Offidani[1,*], L. Corvatta[1], L. Maracci[1], K. Garvey[1], S. Gentili[1], S. Morè[1], V. Mori[1], P. Leoni[1]
[1]Clinica di Ematologia AOU Ospedali Riuniti di Ancona, Ancona, Italy

Background: Revised International Staging System (R-ISS), combining the ISS score with cytogenetics and serum LDH, represents the most recent prognostic model for stratifying newly diagnosed multiple myeloma (MM) patients into three different survival groups. Although data for R-ISS development have been obtained from patients enrolled in clinical trials, this prognostic score has been validated also in real-life scenario (Tandon *et al.*, 2017). In both non-clinical trial setting and IMWG experience, the majority of patients (about 65%) belonged to the intermediate risk group (R-ISS II) that, probably, needs better prognostication.
Aims: The aim of this study was to search for a closer stratification of MM patients with R-ISS II, taking into consideration dynamic aspects, such as therapeutic strategy and response to therapy.
Methods: We investigated the impact of variables, such as initial therapy, response to therapy and maintenance therapy, on PFS and OS in 108 newly diagnosed MM patients classified as R-ISS stage II, diagnosed between 2005 and 2015, who received novel agents such as immunomodulatory drugs and proteasome inhibitors. Score weights of the prognostic factors, found to be significant according to Cox regression model, were determined based on the regression coefficients.
Results: Median age of the 108 patients was 69 years (range 44-93) and 35% of them were older than 75 years. Thalidomide- and lenalidomide-based regimens were administered to 12% and 28% of patients, respectively, whereas 60% of the patients received bortezomib (54%) or carfilzomib-based (6%) regimens as induction therapy. Thirty-eight percent of the study population underwent ASCT and 40% received maintenance therapy. Regarding the response to the therapy, at least CR, VGPR and PR were documented in 35%, 66% and 87% of the patients, respectively. Five-year PFS and OS were 31% and 65%, respectively, similar to those reported by IMWG. Patients who did not achieve a CR, showed a significantly shorter 5yr-PFS (27% *vs* 50%; HR=2.9, 95%CI=1.6-45.0; p<0.0001) and 5yr-OS (53% *vs* 80%; HR=2.8, 95%CI=1.3-5.9; p=0.006) compared to those who did. Moreover, a significant better 5yr-PFS was documented in patients receiving maintenance therapy, compared to those who did not receive maintenance therapy (48% *vs* 20%; HR=1.9, CI95%=1.2-3.3; p=0.010) whereas initial therapy did not affect the outcome. Assigning a value to the variables found to be significantly related to survival measures, according to the above methods, patients were stratified into the following two groups: low-risk (LR), including 38 patients with score 0-1, *i.e.* patients achieving CR and receiving maintenance therapy (score 0) or achieving CR but not receiving maintenance (score 1); high-risk (HR) group, including 70 patients with score 2-3, *i.e.* not achieving CR, who underwent maintenance therapy (score 2) or not achieving CR and not receiving maintenance (score 3). Five year PFS of HR patients was significantly shorter compared to the LR group (20% *vs* 58%; HR=2.5, CI95%=1.6-3.8; p<0.0001), whereas 5-year OS was 57% *vs* 80% (HR=1.9, CI95%=1.1-3.3; p=0.021).
Summary/Conclusions: Our results suggest that in the R-ISS II MM patients,

the outcome of those achieving a CR and undergoing long-term therapy, is comparable with the outcome of the R-ISS I group. On the other hand, patients not achieving CR have a poor outcome, similar to those in the R-ISS III group. Therefore, these patients should require personalized therapy, aimed to achieve CR and to maintain therapy continuously.

PB1955

THE IMPACT OF THE UPDATED IMWG DIAGNOSTIC CRITERIA IN A REAL-LIFE SMM COHORT: A SINGLE CENTER EXPERIENCE

P. Vlummens[1,*], F. Offner[1]
[1]Hematology, Ghent University Hospital, Ghent, Belgium

Background: Recently, an update of the diagnostic criteria for smoldering multiple myeloma (SMM) & multiple myeloma (MM) was published by the International Myeloma Working Group (IMWG). In addition to CRAB criteria, 3 biomarkers of disease were introduced being (i) the presence of >60% clonal bone marrow plasma cells (BMPC), (ii) a serum free light chain ratio (FLC-ratio) >100 & (iii) the presence of >1 focal lesion on whole-body MRI (WBMRI). The introduction of these biomarkers has been shown to identify patients having a 70-80% risk of progression to MM over a 2-year time period.
Aims: To evaluate the impact of IMWG criteria in routine practice, focussing on (i) the prevalence of these biomarkers, (ii) the diagnostic strength of BMPC estimation using bone marrow aspirate *versus* biopsy & (iii) the added role of dynamic contrast-enhanced WBMRI (DCEMRI) in the evaluation of SMM patients.
Methods: We retrospectively identified 28 SMM cases diagnosed between 01/01/09-31/12/14. Sufficient data for analysis was available for 25 patients. All patients underwent standard clinical & laboratory evaluation, bone marrow examination & WBMRI (T1- (+/-Gd) & T2-weighted sequences, diffusion-weighted sequences & additional DCEMRI sequences using time intensity curves). Time to progression (TTP) is defined as time from diagnosis until MM development. Overall survival (OS) is defined as time from diagnosis until death from any cause. Survival analysis was performed using the Kaplan-Meier method & significance was tested using the log-rank algorithm. Intergroup analysis was performed using non-parametric rank-based analysis & correlation was calculated using the Pearson coefficient. Reported p-values are 2-sided with a significance level of 5%.
Results: Median follow-up was 64,1 months (analysis performed on 01/02/2017). No patients had a FLC-ratio >100 at time of diagnosis. Also, no patients with >60% of clonal BMPCs were seen. In 20 patients BMPC counts using both aspirate & biopsy were available. Analysis showed a significant higher estimate of BMPC levels using biopsy (14,8%, SD 4,99) *versus* aspirate (8,45%, SD 6,59) (p=0,002). Sensitivity of bone marrow aspirate was calculated to be 30% considering the 10% BMPC cut-off. Correlation between bone marrow aspirate & biopsy was found in 26,6% of cases. WBMRI-positivity was seen in 9 patients (36%). Progression was seen in 7/9 patients (78%) where only 1/16 WBMRI-negative patients (6,3%) developed MM (p<0,001). Median TTP was 19,9 months *versus* not-reached, respectively (p<0,001). No OS difference was seen between both groups (p=0,453). DCEMRI was positive in 14 patients (56%) thus identifying 5 additional WBMRI-negative patients with measurable bone marrow involvement. No significant difference concerning progression risk was however seen between WBMRI-negative patients being DCEMRI-positive (5/19, 26,3%) or -negative (14/19, 73,7%) (p=0,317). Analysis of baseline data revealed no significant difference concerning age, sex, genetic aberrations or the type of the monoclonal protein between both groups. In patients developing MM, progression was seen based on the development of anemia (5/8, 62,5%), bone pain (3/8, 37,5%), hypercalcemia (1/8, 12,5%) & the development of punched-out lesions (4/8, 50%). No renal insufficiency was seen.
Summary/Conclusions: Our data shows that WBMRI-positivity was the most frequent biomarker in a routine clinical setting. WBMRI-positivity, according to IMWG-criteria, clearly identifies patients with an increased risk of progression as was already shown previously. Although increasing the sensitivity of WBMRI, addition of DCEMRI-sequences didn't have an added benefit. Our sample size was however relatively small. And although IMWG-guidelines do not state clear requirements concerning the preferred type of bone marrow evaluation, our data shows that a bone marrow biopsy can never be ommited in suspected cases of SMM, as an aspirate alone clearly lacks diagnostic strength.

PB1956

RISK FACTORS FOR VENOUS THROMBOEMBOLISM IN 401 MULTIPLE MYELOMA PATIENTS: OBSERVATION OVER A 25-YEARS PERIOD IN A SINGLE INSTITUTION

M. Fernández-Caballero[1,*], F. de Arriba[1], A. Jerez[1], M. D. García[1], V. Vicente[1], V. Roldán[1]
[1]Servicio de Hematología y Oncología Médica, Hospital General Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain

Background: Patients with multiple myeloma (MM) have shown an incidence of 3-10% of venous thromboembolic events (VTE). The introduction of immunomodulatory drugs (IMIDs) in the treatment regimen has further increased the risk of VTE, especially when combined with steroids or chemotherapy (20-30%). Actual guidelines recommend thromboprophylaxis measures, but the proposed strategies are the results of expertise consensus or derived from the extrapolation of data from many studies.
Aims: The aim of this study is to analyze the development of VTE in a large cohort of MM patients, treated for 25 years in a single institution, to assess risk factors suggested in general population, also to confirm the VTE risk of IMIDs based-regimens and the relevance of anticoagulant thromboprophylaxis.
Methods: Four hundred and one consecutive patients diagnosed with MM in a tertiary University Hospital between 1991 to 2015 were included. Data about VTE development, patient characteristics, myeloma-related factors, treatment and thromboprophylatic measures were retrospectively recorded. Multivariable correlates of VTE were assessed using Cox proportional hazards analysis.
Results: The median age at diagnosis was 66 years (range 24-90 years), and 47% were males. The results concerning treatment are extracted from 374 patients who were symptomatic and received myeloma treatment. Among the 164 patients that received IMIDs-based regimen, 27% did not receive any antithrombotic treatment, due to the lack of strong recommendations at the beginning of the use of IMIDs-based regimens. On the other hand, the most common thromboprophylaxis was set with LMWH (54%), followed by low doses of aspirin (13%) and anti-vitamin K (VKA) (6%). Median follow was 40 months (range, 1-293) and VTE occurred in 11% of patients, with a median time from diagnosis of 10 months. IMIDs based-regimen demonstrated to be a risk factor associated on multivariate analysis, and the relevance of thromboprophylaxis has been proved, as the absence of this measure increased significantly the risk. Other factors that have also demonstrated to be independently associated with a higher risk for VTE were: BMI ≥30 kg/m^2, prior Stroke or TIA, prior malignant neoplasm, and the use of high dose of dexamethasone.
Summary/Conclusions: Our data support the actual recommendation of antithrombotic prophylaxis in IMIDs-based regimens, especially in association with high dose of dexamethasone. We recommend the use of a risk factor model including obesity and previous history of thromboembolic disease or cancer, in order to guide the appropriate thromboprophylaxis measures.

PB1957

A PHASE III RANDOMIZED, OPEN-LABEL STUDY OF ISATUXIMAB (SAR650984) PLUS POMALIDOMIDE AND DEXAMETHASONE *VERSUS* POM AND DEX IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

P. Richardson[1,*], M. Attal[2], J. San Miguel[3], F. Campana[4], S. Le-Guennec[5], A.-M. Hui[4], M.-L. Risse[5], K. Anderson[1]
[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, [2]Institut Univ. du Cancer Toulouse Oncopole, Toulouse, France, [3]Clinica Universidad de Navarra, Navarra, Spain, [4]Sanofi, Cambridge, United States, [5]Sanofi, Vitry-Alfortville, France

Background: Treatment for refractory or relapsed and refractory multiple myeloma (RRMM) remains an unmet need. Isatuximab (ISA), an anti-CD38 monoclonal antibody with multiple mechanisms of tumor killing, has shown efficacy and an acceptable tolerability profile in Phase 1/2 studies in patients with RRMM (Richter *et al.* ASCO 2016; Vij *et al.* ASCO 2016; Richardson *et al.* ASH 2016).
Aims: This Phase III, prospective, multicenter, randomized, open-label study (NCT02990338; ICARIA-MM) is being conducted to evaluate the clinical benefit of ISA in combination with Pom and low-dose dex (Pom/dex) *versus* Pom/dex for the treatment of adult patients with RRMM.
Methods: Eligible patients are those with RRMM and demonstrated disease progression within 60 days of the last therapy. Patients will have received at least 2 prior lines of therapy, including lenalidomide and a proteasome inhibitor (bortezomib, carfilzomib, or ixazomib) alone or in combination. Patients will be randomly assigned in a 1:1 ratio to either ISA (10 mg/kg IV on Days 1, 8, 15, and 22 in the 1st cycle; Days 1 and 15 in subsequent cycles) plus Pom (4 mg on Days 1–21) and dex (at 40 mg for patients <75 years of age and at 20 mg for patients ≥75 years of age, on Days 1, 8, 15, and 22) or Pom and dex. Treatment cycles will be 28 days each. Patients will continue therapy until disease progression, occurrence of unacceptable adverse events (AEs), or their decision to discontinue the study, whichever comes first. All patients will be required to provide informed consent. The primary endpoint is progression-free survival (PFS), *i.e.* time from randomization to progressive disease or death from any cause. Response will be determined by IMWG criteria (2016). Key secondary endpoints include overall response rate and overall survival (OS). Safety evaluations include treatment-emergent AEs/serious AEs (including infusion-associated reactions), laboratory parameters, vital signs, and assessment of physical examination.
Results: Approximately 300 patients (150 in each arm) are expected to be enrolled in this study. Statistical analyses will be conducted according to a prespecified plan. The first patient was recruited in January 2017.
Summary/Conclusions: This Phase III, prospective, multicenter trial will provide a placebo-controlled evaluation of the efficacy and safety of ISA+Pom/dex, a combination which has previously reported preliminary clinical activity and manageable toxicities in heavily pretreated patients with RRMM in a single-arm Phase Ib study.

PB1958

LONG TERM SURVIVAL OF IGM MULTIPLE MYELOMA AND WALDENSTRŐM'S MACROGLOBULINEMIA PATIENTS

M. Kraj[1,*], R. Pogłód[2], B. Kruk[1], K. Warzocha[3], M. Prochorec-Sobieszek[1]
[1]Department of Diagnostics for Hematology, [2]Department of Transfusion Medicine, [3]Department of Hematology, Institute of Hematology and Transfusion Medicine , Warsaw, Poland

Background: IgM multiple myeloma (MM) and Waldenström's macroglobulinemia (WM) are two hematologic malignancies with the common finding of IgM monoclonal gammopathy. IgM MM is a rare and poorly characterized disease.
Aims: The paper presents clinical and laboratory results of long term observations of 15 IgM MM patients selected from a group of 889 MM patients (1.6%) diagnosed and treated for several years at the Institute of Hematology and Transfusion Medicine in Warsaw as well as 15 WM patients investigated and treated at the same period of time at our hospital.
Methods: For analysis of serum proteins new Hevylite and Freelite tests (Binding Site Ltd Birmingham, UK) were applied as well as immunofixation using Sebia (Lisses, France) reagents. Fresh and archived frozen serum samples were used for the study.
Results: The clinical presentation of IgM MM patients is heterogenic starting with typical form for non IgM MM through predominant form with characteristic hyperviscosity syndrome and severe disease course to slow and latent form with survival time up to dozens of years. In 2 patients diagnosis of IgM MM was preceded by a 3-year period of monoclonal gammopathy of undetermined significance (MGUS) while in 4 patients (27%) diagnosis of WM was preceded by a 108, 84, 78, 9 months period of IgM MGUS. Median real overall survival of IgM MM patients was 50 months, 5 patients (33%) survived above 7 years and 2 patients (13%) survived above 12 years. Median overall survival of WM patients was 108 months, 7 patients (47%) survived above 10 years, 3 patients (20%) survived above 15 years. Lytic bone lesions were found in 11 (73%) IgM MM patients and in 3 (20%) WM patients. Urine monoclonal free light chains (FLC) detected by immunofixation was present in 60% of IgM MM patients and increased concentrations of involved monoclonal FLC and abnormal FLC κ/λ ratio in serum (by Freelite) in 75% of IgM MM patients. It was shown that IgM clonality in IgM MM and WM patients can be determined by using immunoglobulin heavy chain /light chain (HLC) immunoassays- Hevylite. Immunofixation and HLC ratios were concordant in all assessed IgM MM and WM patients. In IgM MM patients the suppression of uninvolved polyclonal IgM- detectable by using IgM HLC test - has prognostic significance. The evaluation of IgM HLC in 13 patients with IgM MM at diagnosis revealed a decreased concentration of uninvolved IgM (HLC IgMκ <0.33 g/L, HLC IgMλ <0.20 g/L) in 5 patients and normal values in 8 patients. Median overall survival in patients with a decreased uninvolved IgM was 15 months and in patients with normal polyclonal IgM 55 months ($p<0.01$).
Summary/Conclusions: 33% of IgM MM patients survive above 7 years and 13% above 12 years while 47% of WM patients survive above 10 years and 20% above 15 years. Suppression of uninvolved polyclonal IgM (detectable by using HLC IgM test) at the time of IgM myeloma diagnosis is unfavorable prognostic factor.

PB1959

MULTISITE PERFORMANCE EVALUATION STUDY OF THE BD ONEFLOW PLASMA CELL DISORDERS PANEL

B. Balasa[1,*], D. van Hoof[2], C. Fox[2], E. Deal Becker[2], J. perkins[2], C. Green[2], C. Bessette[2], K. Judge[2]
[1]Medical Affairs, [2]BD Biosciences, San Jose, United States

Background: The BD OneFlow solution for plasma cell disorders incorporates a standardized flow cytometry approach based on the EuroFlow (EF) Consortium liquid reagent system. The BD OneFlow solution enables reproducible identification and discrimination of distinct cell populations by combining standardized assays, setup reagents, and protocols. The plasma cell disorders (PCD) panel is composed of the BD OneFlow PCST (Plasma Cell Screening Tube) and BD OneFlow PCD. BD OneFlow PCST helps differentiate normal plasma cell populations from those requiring follow-up. The BD OneFlow PCD classification tube helps differentiate abnormal from normal plasma cell populations. The BD OneFlow PCD tube, when run in parallel with BD OneFlow PCST tube, characterizes the abnormal plasma cell population for identification of plasma cell disorders.
Aims: The objective of this study was to compare the accuracy between the BD OneFlow PCD system and the EF liquid comparator system.
Methods: De-identified remnant human bone marrow specimens (n=48) were collected at two study sites and tested in an unblinded manner within 26 hours of draw. Specimens were simultaneously stained with BD OneFlow PCD and BD OneFlow PCST tubes and EF specified liquid reagents. Acquisition and analysis were performed on a BD FACSCanto II instrument using standardized acquisition and analysis templates in BD FACSDiva software. For qualitative endpoints, overall agreement, negative agreement, and positive agreement, along with their one-sided lower 95% confidence limits, were calculated. For accuracy quantitative endpoints (% positive plasma cell population), the slope, intercept, and 95% confidence limits of the slope from a Deming regression were calculated for the BD OneFlow *vs* EF methods.
Results: The BD OneFlow PCD system is in 100% agreement (26 of 26) with the EF system in classifying patients as having normal plasma cell populations. BD OneFlow PCD system is in 100% agreement (22 of 22) with the EF system in identifying patients with a plasma cell disorder. Furthermore, the BD OneFlow PCD system correctly identified 100% of patients who had a plasma cell disorder based on clinical results.
Summary/Conclusions: The multisite evaluation between the BD OneFlow PCD system (PCST and PCD tubes) and the EF liquid reagent system was fully concordant in identifying patients with abnormal plasma cell populations. Additionally, all subjects identified as having plasma cell disorder based on clinical results were identified as having plasma cell disorder by the BD OneFlow PCD system. The BD OneFlow PCD panel is a fully standardized and validated system for aiding in the diagnosis of plasma cell disorders from bone marrow specimens.
BD OneFlow PCD and BD OneFlow PCST are for in Vitro Diagnostic Use; CE Marked to the European In Vitro Diagnostic Medical Device Directive 98/79/EC. 23-19565-00.

PRACTICE GAPS AND BARRIERS TO OPTIMAL MANAGEMENT OF MULTIPLE MYELOMA PATIENTS : RESULTS FROM A MIXED-METHODS STUDY IN 8 EUROPEAN COUNTRIES

S. Murray[1], M. Mohty[2,*], S. Peloquin[1], N.W. van de Donk[3], S. Leitao[4], S. Labbé[1], S. West[5], E. Hofstädter-Thalmann[6], P. Sonneveld[7]
[1]AXDEV Group, Brossard, Canada, [2]Hopital St Antoine, University Pierre & Marie Curie, Paris, France, [3]Department of hematology, VU University Medical Center, Amsterdam, Netherlands, [4]Janssen Pharmaceutical, Barcarena, Portugal, [5]Royal Mardsen, London, United Kingdom, [6]Janssen Pharmaceutical, Vienna, Austria, [7]Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: Previous studies have identified gaps and barriers in Multiple Myeloma (MM) patient care, especially in relation to treatment decision making. However, only few studies have aimed at better understanding the practice gaps, from the healthcare providers' perspectives, with the purpose to investigate the root causes of those gaps and find solutions to alleviate the challenges.
Aims: We conducted a study to identify the practice gaps and challenges in the diagnosis, treatment and management of MM patients, as experienced and reported by medical oncologists, haematologists and hemato-oncologists (HEM) and oncology nurses (NU) in 8 European countries between February 2016 and June 2016.
Methods: This mixed methods ethics-approved study included exploratory semi-structured interviews (phase 1) designed to generate in-depth discussion around challenges in the diagnosis, treatment and management of MM, followed by a quantitative online survey (phase 2) designed to validate the findings from the interviews with a larger sample. Practice gaps were identified through combined analysis of data from the in-depth interviews and online surveys.
Results: A total of 364 participants (HEM=281, NU=83) from France (n= 58), Germany (n=58), Russia (n=41), Spain (n=58), Italy (n=50), the UK (n=58), the Netherlands (n=16), and Belgium (n=25) participated in this study. Thirty-nine (39) interviews were conducted (HEM=28, NU=11) and 325 participants completed the online survey (HEM=253, NU=72). A majority (79%) of the sample had more than 10 years of clinical practice experience and over a third (39%) had over 20% of MM patients in their patient caseload. Three key findings were identified in the management of MM patients: 1) challenges in managing treatment side-effects. Forty percent (40%) of HEM reported lack of skills in managing cardiovascular side effects or symptoms. Over a third of HEM reported difficulties in managing fatigue (40%), skin toxicities (35%) or peripheral neuropathy (34%). NU reported being challenged by the management of renal insufficiency as a side effect or symptom (46%), peripheral neuropathy (36%), thrombosis (37%), and skin toxicities (33%). Additionally, 2) NU reported challenges in communicating with patients and educating them around their disease, especially in relation to treatment outcomes and long term side effects. For example, 51% of NU reported a lack of skills discussing sexual issues as consequences of the disease/treatment. Finally 3) there was a large variability across countries in the guidelines followed by HEM and NU for the treatment and management of MM patients. Detailed results, including country-specific analyses and investigation of the practice gaps' causalities, will be presented.
Summary/Conclusions: These findings provide real-life recent evidence of the challenges of HEM and NU in relation to specific aspects of the management of patients with MM with 3 main areas, challenges in managing side effects, communication with patients and leverage of guidelines which show differences between HEM and NU but also between countries. The findings support the needs for the development of tailored clinical tools, educational activities and performance improvement interventions, adapted to the local context at a country level. Efforts should aim to address those current challenges before new therapies, such as immunotherapies, become available.

These new agents, with their own specific safety and side effect profiles, are likely to add to the challenges already experienced by health care providers in their management of patients with MM.

PB1961

THE EXPRESSION OF APRIL BY MULTIPLE MYELOMA CELLS AND THEIR ROLE IN THE EVOLUTION OF MULTIPLE MYELOMA

A. Xekalou[1], P. Kanellou[2,*], R. Vyzoukaki[3], M. Kokonozaki[3], C. Pappa[4], M. Devetzoglou[5], A. Sfyridaki[6], F. Psarakis[7], M. Alexandrakis[8]
[1]Pathology, Venizelion Hospital, [2]Blood bank, [3]Laboratory of Haematology, University Hospital of Heraklion, [4]Department of Internal Medicine, Venizelion Hospital, [5]Department of Haematology, University Hospital of Heraklion, [6]Blood bank, Venizelion Hospital, Heraklion, [7]Department of Surgery, Hospital of Sitia, Sitia, [8]Medical School, University of Crete, Heraklion, Greece

Background: Multiple myeloma (MM) is a malignant proliferation of plasma cells and is characterized by the accumulation of monoclonal plasma cells in bone marrow that secrete pathological monoclonal immunoglobulins. Inductive factors secreted by tumor cells and other cells of the marrow microenvironment play an important role in disease progression. APRIL, by initial letters A Proliferation Inducing Ligand, is a member of the family of pro TNF, one of the main factors for the survival of immature and activated B cells. One of the main signal transduction pathways for activation of myeloma cells is NF-κB. APRIL, can directly activate the NF -κB and has been found by studies that are the most important factors for the survival of healthy and myeloma cells.
Aims: Aim of this study was the study of APRIL expression in myeloma cells in the bone marrow of patients with MM and their possible association with cell proliferation markers.
Methods: We studied 42 newly diagnosed patients with MM, 19 women and 23 men, aged 64,1±10,4 years. According to the ISS stage, 14 were stage I, 11 stage II and 17 stage III . Regarding the type of paraprotein that had been found, 23 IgG, 14 IGA and 5 patients with light chains. Serum samples and bone marrow biopsy samples were obtained from all patients prior to the initiation of treatment. Patients with impaired hepatic and renal function, chronic or acute infections, chronic inflammatory or autoimmune disorders or other malignancies were excluded from the study. We also excluded patients who were taking anti-inflammatory drugs, corticosteroids or bisphosphonates. 20 age and sex-matched healthy volunteers, were used as controls. The levels of IL-10 and IL-6 in the serum were measured by ELIZA. Bone marrow infiltration by neoplastic plasma cells was calculated in%. The expression of cell proliferation index was calculated in BM biopsy sections with immunohistochemistry techniques. The expression of APRIL was also calculated with immunohistochemistry. For the control of the process we used positive control. The assessing of the staining was checked in the optical microscope, over the whole surface of each sample and had to do with the cytoplasm of tumor cells. It was dotted with brown ting. Non-specific staining was observed at the other cellular components of BM. The degree of staining expression was evaluated as the percentage of neoplastic plasma cells and according to the intensity of staining in four-grade scale 0: negative,+1 weak, +2 moderate and +3 intense staining. Then the proportion of plasma cells stained for each type of staining separately, was calculated using the H-score method (Histoscore), based on the formula:% *% * 1+2+3% *. Our aim is to prove if the intensity of expression is associated with disease stage.
Results: Statistically significant differences were observed between patients and controls for all parameters measured (p <0.001 in all cases) . All values of the measured parameters increased in parallel with the ISS stages of the disease (APRIL p <0,005, bone marrow infiltration p <0.03 Ki-67p <0,01, IL-10 p <0,001, IL-6, p <0.001) Eventually APRIL correlated significantly with all measured parameters *e.g.* BM infiltration r=0,386, p <0,01, with Ki-67 r=0,390 p <0,01 IL-10 r=0,497 p <0,001, IL-6, r=0,484 p <0,001).
Summary/Conclusions: Increased expression of APRIL ligand plays an important role in development and pathobiology of MM and may be an important therapeutic target in the treatment of MM.

PB1962

DEVELOPMENT OF SECOND PRIMARY MALIGNANCY AFTER TREATMENT WITH LENALIDOMIDE: A SINGLE CENTRE EXPERIENCE

F. McGlynn[1,*], E. Groarke[1], S.W. Maung[1], R. Desmond[1], J. McHugh[1], H. Enright[1]
[1]Haematology, Tallaght Hospital, Dublin 24, Ireland

Background: Lenalidomide is a well-established and effective treatment for haematological malignancies particularly multiple myeloma (MM), but also lymphoma and myelodysplastic syndromes. It can be used as both a single agent and in combination with dexamethasone or other chemotherapeutic agents. A previous study in myeloma patients demonstrated an increased incidence of second primary malignancy (SPM) in patients treated with lenalidomide and dexamethasone (7% - 8%) compared to those treated with dexamethasone and placebo (2%>3%) [1 - 3].
Aims: We reviewed all patients treated with Lenalidomide in a single centre from January 2008 to May 2016 to establish the real-world of SPM.
Methods: A database of patients (n=137) treated with lenalidomide in the specified timeframe was created from pharmacy records. A search of the hospital's patient management system was performed to identify: (1) type and date of primary haematological diagnosis, and (2) type and date of second malignancy based on histology. An analysis of the data was performed to establish: (1) incidence of SPM, (2) latency between primary haematological malignancy and SPM, (3) latency between starting lenalidomide and SPM, (4) types and subtypes of SPM.
Results: The majority of patients were treated for Multiple Myeloma (67%). Other primary haematological diagnoses included myelodysplastic syndrome(MDS), Non-Hodgkin Imphoma(NHL), and Idiopathic myelofibrosis(IMF). The incidence of SPM post-treatment with lenalidomide was 12 patients (8%). 9 patients had a diagnosis of second malignancy prior to starting lenalidomide treatment. The median latency between starting lenalidomide and SPM diagnosis was 24 months.. The median latency between primary haematological diagnosis and SPM diagnosis was 37 months. The most common types of SPMs were haematological; 7 (64%), patients had t-MDS 3 (27%), 3 Acute Myeloid Leukemia(AML) (27%), and 1 patient developed B-cell Lymphoma (9%). Next most common was skin malignancy; 3 (27%), all squamous cell carcinoma (SCC). One patient developed prostate carcinoma (9%).
Summary/Conclusions: Studies show the estimated incidence of SPM in MM to lie between 2%>10% over a 25 year period [5]. This study demonstrates a higher incidence (12%), however it includes patients treated for other primary haematological malignancies. This data demonstrates a similar incidence of SPM to previous studies (8%) post-treatment with lenalidomide [1 - 3]. Haematological malignancy was the commonest SPM however this differs from other studies which showed a majority of solid tumors (including skin malignancy) [4]. We found t-MDS/AML and skin malignancy to be the most significant SPMs. This is in agreement with some published reports [4, 5]. No analysis was made of patient specific risks or disease specific risks. This data supports the conclusion that the risk of SPM must be considered before commencing a patient on lenalidomide therapy.

SOLITARY PLASMACYTOMA. A SINGLE-CENTRE RETROSPECTIVE STUDY

K. Velazquez Kennedy[1,*], C. Martinez-Geijo Román[1], M.J. Blanchard[1], F.J. López Jiménez[1]
[1]Haematology, Hospital Ramón y Cajal, Madrid, Spain

Background: A solitary plasmacytoma (SP) is a rare neoplastic mass of monoclonal plasma cells that can either be localized in bone (solitary plasmacytoma of bone, SPB), or soft tissue (extramedullary plasmacytoma, EMP), without evidence of multiple myeloma (MM). The median age at diagnosis is 65 years. Some patients present a monoclonal band (MB) at diagnosis, and a proportion progresses to MM. The low incidence of this entity has prevented reaching definite conclusions with regards to prognostic factors and treatment.
Aims: In this study we retrospectively analysed the clinical presentation, treatment and outcome of all patients with SP treated in our centre in order to establish relevant prognostic clinical features and management options.
Methods: Between 1985 and 2016, 27 patients with SP (20 SPB, 7 EMP) were treated in Ramon y Cajal Hospital (Madrid), with a median follow up of 8 years. The time to relapse, progression to MM or death was measured in months. The progression free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method. The comparison of PFS/OS was performed using the Log Rank test. Student´s T test was used to compare the average age at diagnosis. To determine the association between the presence of MB or the subtype of SP, and progression to MM, we used Fisher's exact test. All statistical analysis was performed with the software SPSS 24.0.
Results: The average age at diagnosis was 56 years (±18): 51 (±17) for SPB, and 72 (±5) for EMP (p<0.05), with a male:female ratio of 2.4:1. The most frequent location was the axial skeleton (80%) for SPB, and the airway in the case of EMP (57%). In most cases, the initial symptom of SPB had been pain

(45%), and local discomfort for EMP. 52% of patients presented a MB at diagnosis, without significant differences between subgroups. With regards to treatment, combined therapy was the preferred option in the case of SPB (60%), whereas unimodal treatment strategies were more frequently used in EMP (86%). 11 of the 20 patients with SPB progressed to MM (55%) in a median time of 4 years, while none of the patients with EMP progressed (p<0.05). The 5 year PFS and OS was 61% and 90% respectively, 31% and 74% at 10 years. Although a tendency towards a higher PFE was observed in the EMP group, it was not statistically significant. No differences were found in PFS/OS between age groups (<60 or ≥60 years), axial *vs* appendicular skeleton location in SBP, type of treatment received, or the presence of MB. Furthermore, no association was found between the presence of MB at diagnosis and progression to MM (Figure 1).

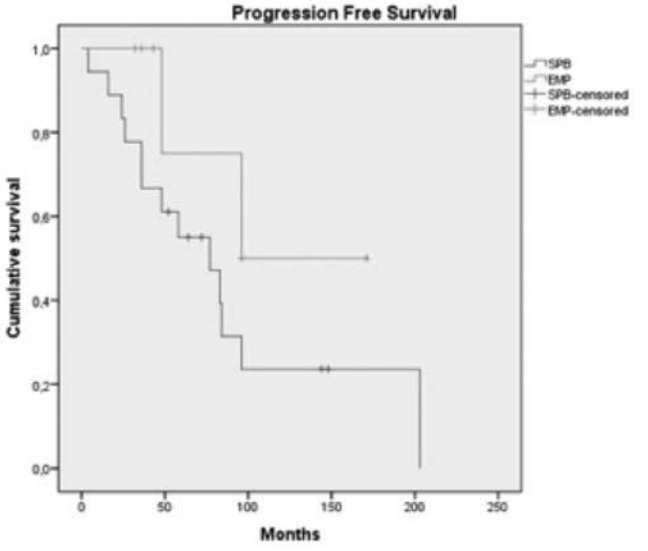

Figure 1.

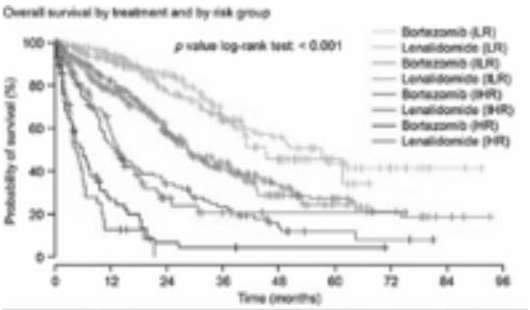
Summary/Conclusions: The age at diagnosis of SPB is significantly lower than EMP. Moreover, the progression to MM is notably higher in this group of patients. These distinct characteristics in clinical presentation and outcome could suggest a biological difference between both entities.

PB1964

RISK STRATIFICATION ALGORITHM USING REAL-WORLD DATA FROM PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA: DESCRIPTION OF CLINICAL OUTCOME BY TREATMENT REGIMEN

R. Hajek[1,*], M. Delforge[2], M. Raab[3], J. Radocha[4], J. Straub[5], W. Bouwmeester[6], Z. Szabo[7], L. Pour[8], S. Gonzalez-McQuire[7], V. Maisnar[4]
[1]Department of Haemato-oncology, University of Ostrava, Ostrava, Czech Republic, [2]Department of Hematology, UZ Leuven, Leuven, Belgium, [3]Department of Internal Medicine , University Hospital Heidelberg, Heidelberg, Germany, [4]4th Department of Medicine , Charles University Hospital and Faculty of Medicine, Hradec Kralove, [5]Departments of Internal Medicine and Hematology, Prague General Teaching Hospital, Prague, Czech Republic, [6]Pharmerit International, Rotterdam, Netherlands, [7]Amgen (Europe) GmbH, Zug, Switzerland, [8]Department of Internal Medicine, University Hospital Brno and Faculty of Medicine, Brno, Czech Republic

Background: Estimation of survival for patients with RRMM, requires prognostic tools that define the relative risk of death after first relapse. We recently developed a risk stratification algorithm (RSA) using real-world data from the Czech Registry of Monoclonal Gammopathies (RMG). Our RSA uses patient and disease characteristics at diagnosis and at initiation of second-line treatment (2L), and previous treatment outcomes to stratify patients based on their overall survival (OS) expectations from initiation of 2L treatment (Hajek *et al.* Blood 2016). The value of such an algorithm depends on its validation, but also on understanding the evidence that explains these differences in survival expectations.
Aims: To describe 2L treatment patterns by RSA group and to report OS, progression-free survival (PFS) and response by treatment received in 2L per RSA risk group.
Methods: Data were collected from the Czech RMG for patients aged ≥18 years who were diagnosed with symptomatic MM between May 2007 and April 2016 and in whom 2L treatment had been initiated. Predictors of OS from the start of 2L were identified using Cox regression analyses. Hazard ratios for each OS predictor were multiplied to obtain an overall score for each patient. Risk groups were defined based on the overall score. To provide optimal patient stratification, cut-offs of the score were estimated using K-adaptive partitioning for survival (KAPS) analysis.
Results: Data from 1418 patients were analysed. KAPS analysis defined four groups based on risk of death: low (LR; score ≤ 4.1; n=403), intermediate-low (ILR; score 4.2–10.3; n=635), intermediate-high (IHR; score 10.4–20.1; n=237) and high (HR; score ≥20.2; n=143) risk. Median OS (months) was 57, 29, 13 and 5 for the LR, ILR, IHR and HR groups, respectively. Following stratification, compared with patients in the lower risk groups, a higher proportion of those in the HR group had LDH levels above 360 U/L and an Eastern Cooperative Oncology Group Performance Status of 3–4 at initiation of 2L. Treatments received at 2L were similar across all risk groups, with bortezomib and lenalidomide being the most common 2L treatments. Patients who received bortezomib at 1L were often given lenalidomide or thalidomide at 2L and those who received thalidomide at 1L were frequently given bortezomib at 2L. This suggests that 2L treatment choice was not defined by the underlying risk of death for each patient, but rather by the type of previous treatment. For patients receiving bortezomib at 2L, median OS (months) from start of 2L was 57, 29, 13 and 6 (Figure 1), and median PFS (months) was 18, 12, 8 and 3 in the LR, ILR, IHR and HR groups, respectively. A very good partial response or better (VGPR+) was reported for 29.3%, 31.0%, 18.7% and 19.6% of patients in the LR, ILR, IHR and HR groups, respectively. For patients receiving lenalidomide at 2L, median OS (months) was 45, 29, 14 and 5, and median PFS (months) was 20, 12, 10 and 3 for patients in the LR, ILR, IHR and HR groups, respectively. A VGPR+ was reported for 33.6%, 22.9%, 26.0% and 7.1% of patients in the LR, ILR, IHR and HR groups, respectively.



Treatment at second line	Overall survival	Low risk	Intermediate-low risk	Intermediate-high risk	High risk
Bortezomib	Median (95% CI)	57 (47–68)	29 (25–32)	13 (10–17)	6 (4–8)
	Hazard ratio (95% CI)	Reference	2.1 (1.5–2.8)	4.1 (2.9–5.8)	10.2 (6.9–15)
	p value		< 0.001	< 0.001	< 0.001
Lenalidomide	Median (95% CI)	45 (33–58)	29 (22–35)	14 (10–17)	5 (3–7)
	Hazard ratio (95% CI)	Reference	2.0 (1.4–2.8)	4.1 (2.7–6.4)	14.6 (9.1–24)
	p value		< 0.001	< 0.001	< 0.001

CI, confidence interval; HR, high risk; IHR, intermediate-high risk; ILR, intermediate-low risk; LR, low risk.

Figure 1.

Summary/Conclusions: The RSA effectively stratifies patients according to OS from initiation of 2L. However, these results must be validated in an external dataset. The outcomes of each risk group are mainly driven by the underlying risk of death at initiation of 2L; treatment with bortezomib or lenalidomide provided similar outcomes independent of risk group. Use of our RSA at 2L would support physician decision making to improve patient specific care.

PB1965

LACK OF CD56 EXPRESSION IN MULTIPLE MYELOMA PATIENTS WITH RISS 2 DISEASE IS ASSOCIATED WITH WORSE PROGNOSIS AND ABOLISHED WITH AUTOLOGOUS STEM CELL TRANSPLANTATION

M. Skerget[1,*], B. Skopec[1], H. Podgornik[1], D. Zontar[1], K. Rebersek[1], T. Furlan[1], P. Cernelc[1]
[1]Department of Hematology, University Clinical Center Ljubljana, Ljubljana, Slovenia

Background: Multiple myeloma (MM) is a hematologic disease in which accumulation of malignant plasma cells and high levels of monoclonal protein and free light chains lead to bone marrow failure, hypercalcemia, lytic bone lesions and renal failure. Myeloma cells are distinguished from normal plasma cells by an aberrant immunophenotype.They express CD56, which is present in 70-80% and can be used to distinguish myeloma cells by flow cytometry. The expression of CD56 is constant throughout the course of the disease. The lack of CD56 expression in myeloma cells decreases the adherence of myeloma cells to the cell matrix and is associated with higher levels of bone marrow infiltration and peripheral blood involvement, higher incidence of extramedullary disease, renal insufficiency, Bence Jones protein, plasma cell leukemia and t(11;14). The lack of CD117 expression is associated with higher levels of bone marrow infiltration, renal impairment, elevated β2-microglobulin and cytogenetic

aberrations including t(11;14), t(4;14) and del(13q). CD28 expression is present in 15 – 45% of patients and is associated with unfavorably cytogenetic changes including t(4;14) and del(17p) and shorter PFS and OS despite aHSCT.
Aims: Aim of our retrospective study was to evaluate the impact of CD56, CD117 and CD28 expression on clinical characteristics and PFS in newly diagnosed MM patients treated with bortezomib based induction therapy.
Methods: We retrospectively analyzed 110 newly diagnosed MM patients from our national registry that had data available at the time of diagnosis. Immunophenotype was determined using a panel consisting of CD19/CD38/CD45/CD56/CD138 to distinguish and to enumerate MM cells. Monoclonal antibodies directed against CD20, CD28, and CD117 were used additionally. All samples were routinely tested for the presence of recurrent chromosomal aberrations, *i.e.* del 1p, amp1q, del6q, amp15q, del13, del17, t(4;14), t(14;16) and t(11;14) using commercially available DNA probes.
Results: We found no association between CD56 expression and age, gender, elevated LDH, cytogenetic risk or RISS stage. We found a strong association between lack of CD56 expression and light-chain only or asecretory myeloma. There was an association between CD28 expression and female gender (Table 1). In multivariate analysis including age, elevated creatinine, RISS, aHSCT , CD28, CD56 and CD117 expression, CD56 expression was associated with a 47% reduced hazard for progression (Exp(B)=0.527, p=0.03). Other factors with statistically significant impact on progression were aHSCT and age. In patients not undergoing aHSCT lacking CD56 expression in comparison to those with an aberrant CD56 expression, the difference in PFS was statistically significant with a PFS of 8 *vs* 18 Month (Log Rank p=0.088, Breslow p=0.046). When stratified according to RISS stage, only patients in stage 2 disease had a significant reduction in PFS with lack of CD56 expression.

Table 1.

Association of CD56, CD28 and CD117 expression with clinical factors.

	CD56		CD28		CD117

Light chain/asecretory myeloma	7.307	0.007	0.541	0.763	1.421	0.491
RISS	0.411	0.814	1.645	0.439	2.641	0.267

Summary/Conclusions: CD56 expression was prognostic for PFS only in the patient cohort not undergoing aHSCT. As previously reported aHSCT seems to abrogate the negative impact of CD56 negativity. We propose CD56 expression to be used as a prognostic marker in patients with RISS 2 stage disease and when possible these patients should undergo aHSCT.

PB1966

AUTOLOGOUS TRANSPLANTATION FOR MULTIPLE MYELOMA IN GERMANY – REAL-WORLD DATA FROM A NATIONWIDE, MULTI-INSTITUTIONAL SURVEY IN 2015-2016

M. Merz[1,*], L. Kellermann[2], W. Poenisch[3], U. Mahlknecht[4], S. Fries[5], H. Goldschmidt[6]
[1]Klinik für Innere Medizin V, Universitätsklinikum Heidelberg, Heidelberg, [2]OncologyInformationService, Freiburg, [3]Universitätsklinikum Leipzig, Leipzig, [4] Innere Medizin Hämatologie und Internistische Onkologie, Kplus-Gruppe GmbH - St. Lukas Klinik, Solingen, [5]Onkologische Schwerpunktpraxis, Bamberg, [6]Nationales Centrum für Tumorerkrankungen (NCT), Heidelberg, Germany

Background: A nationwide, multi-institutional survey was performed in 2015 and 2016 to analyse routine practice for myeloma patients outside clinical trials in Germany.
Aims: We aimed to investigate implementation of autologous stem cell transplantation (ASCT) into treatment of patients with newly diagnosed or relapsed multiple myeloma (MM) in Germany.
Methods: The analysis is based on a database built from university hospitals (UH), community hospitals (CH), office-based hematologists (OBH). Anonymized data were collected online based on retrospective chart review. The completeness and the plausibility of the data were verified in real-time and by online personal checks. We investigated which institutions initiated treatment in patients with ASCT, which were the characteristics for patients not-considered eligible for transplantation, how stem cell mobilization was performed, how many patients dropped out before planned transplantation and what were the frequencies of tandem ASCT and ASCT for relapsed disease.
Results: Data from 515 patients from 51 centres were available for the first half of 2015 and from 867 patients from 52 centres for the first half of 2016. There were 40% (2015) and 32% (2016) pts considered as eligible for ASCT in 1st line. Although the proportion of patients older than 69 years was not significantly different between health care providers in 2015 and 2016 (2015: 47%UH, 60%CH, 49%OBP / 2016: 54%UH, 56% CH, 47%OBP), patients were considered more often transplant-eligible in UH (2015: 49% / 2016: 53%) than in CH (2015: 29% / 2016: 21%) or OBH (2015: 45% / 2016: 26%). In first-line treatment, 52% of patients eligible for SCT received mobilization chemotherapy in addition to induction therapy. More than 80% of patients received a cyclophosphamide-based chemotherapy in combination with G-CSF for stem cell mobilization in 2015 and 2016. Most participating institutions aimed at collection of three sufficient stem cell transplants (2015: 48% / 2016: 46%). Once patients completed stem cell mobilization, 92% continued to high-dose chemotherapy and 92% of them received ASCT finally. 25% of transplant patients were treated with tandem ASCT in 1st line. In 2015, 8% of patients and 1% of patients in 2016 were considered eligible and were ultimately treated with ASCT for relapsed disease. The most frequent reason for transplant-eligible patients not receiving ASCT were withdrawal of patients consent (first-line: 15%, second-line: 39%).
Summary/Conclusions: With our current analysis of a nationwide survey performed with different health care providers in Germany we demonstrate that implementation of ASCT is strongly influenced by the institution initiating primary therapy. Age does not seem to impact usage of ASCT compared to concomitant disease or patients´ and doctors´ preferences. Patients predominantly collect three autologous transplants, enabling a possible tandem ASCT and ASCT for relapsed disease.

PB1967

MODIFIED HYPERCVAD *VERSUS* BORTEZOMIB-HYPERCVAD IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

E. Scott[1,*], M. Saraceni[1], S. Jiing[1], S. Mongoue-Tchokote[1], R. Maziarz[1], E. Medvedova[1]
[1]Hematology and Oncology, Oregon Health and Science University, Portland, United States

Background: Multiple myeloma (MM) is an incurable plasma cell malignancy, in which aggressive relapses may require salvage cytotoxic infusional chemotherapy. Several clinical trials demonstrating the efficacy of bortezomib led to institutional practice changes where vincristine was replaced with bortezomib in the modified hyperCVAD (mod-CVAD) regimen, creating a new treatment regimen, 'bortezomib-hyperCAD' (bort-CVAD).
Aims: The primary objective is to describe the safety and efficacy of the hyper-CVAD regimen with vincristine or bortezomib in patients with relapsed or refractory MM treated at Oregon Health and Science University.
Methods: IRB approval was obtained to perform this retrospective analysis. We describe the effectiveness and tolerability of the 2 regimens among 33 patients with relapsed and/or refractory multiple myeloma (RRMM). Patients who received ≥1 cycle of mod-CVAD (n= 15) or bort-CVAD (n= 18) from Jan 1 2011 and Dec 31 2015 at the Knight Cancer Institute were included. Most patients were previously treated with/refractory to proteasome inhibitors (97%/76%) or immunomodulatory agents (82%/68%) respectively, 13 received prior autologous stem cell transplant (auto-HCT), the median number of prior lines was 3 (range 1-8). High risk cytogenetic factors t(4;14), t(14;16), or del 17p were present in 8 and extramedullary disease in 13 patients overall.
Regimens contained cyclophosphamide 300 mg/m2 IV every 12 hours for 8 doses; doxorubicin 9 mg/m2/day continuous IV infusion every 24 hours and dexamethasone 40 mg by mouth on days 1-4; vincristine 0.4mg continuous IV infusion every 24 hours on days 1-4 (mod-CVAD) OR bortezomib 1.3mg/m2 SQ on day 1 and 4 (bort-CVAD). All patients received MESNA 350 mg/m2 IV every 24 hours on days 1 through 4; granulocyte colony-stimulating factor 24-48 hours following the completion of chemotherapy; and standard infectious prophylaxis. International Myeloma Working Group uniform response and European Society for Blood and Marrow for minor response (MR) criteria were used.
Results: The median number of cycles given was 2 (range 1-6). Cycles were repeated every 3 to 4 weeks. Median follow up was 48 and 33 months in mod-CVAD and bort-CVAD respectively. The ORR was 40% in the mod-CVAD group: 6 partial (PR), 6 minor (MR), and 3 stable disease (SD) compared to 44.4% in the bort-CVAD group: 1 complete response, 7 PR, 2 MR, 6 SD and 2 progressive disease (Fisher's exact p=0.80). A total of 13 patients proceeded to auto-HCT. Median progression-free and overall survival for all patients were 6 and 11 months respectively, which was comparable between arms (Log rank test p=0.6635 and 0.7369). New or worsening of peripheral neuropathy occurred in 2 and 4 patients in the mod-CVAD and bort-CVAD groups respectively. There was no statistically significant association between treatment and febrile neutropenia, emergency department visits, hospitalizations, or peripheral neuropathy (Fisher's exact test P value >0.05). There were no statistically significant differences in safety and tolerability between treatment arms. Three and 6 patients in the mod-CVAD and bort-CVAD arms discontinued therapy due to toxicity or treatment complications respectively.
Summary/Conclusions: Overall effectiveness and safety outcomes were similar between mod-CVAD and bort-CVAD, with both regimens demonstrating an impressive response rate among heavily pre-treated patients with relapsed/refractory disease. This is a useful salvage strategy to gain rapid dis-

ease control; and as a bridge to other therapies including stem cell transplant and novel therapies.

PB1968

EFFICACY AND SAFETY OF LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/ REFRACTORY MULTIPLE MYELOMA: A REAL LIFE EXPERIENCE FROM TURKEY

G. Saydam[1,*], N. Soyer[1], P. Patır[1], A. Uysal[1], M. Duran[1], R. Durusoy[2], F. Sahin[3], F. Vural[3], M. Tobu[3], M. Tombuloglu[3]
[1]Hematology, Ege University Hospital Internal Medicine, Bornova, [2]Public Helath, Ege University Medical School, [3]Hematology, Ege University Hospital Internal Medicine, Izmir, Turkey

Background: Lenalidomide, an immunomodulatory drug, was approved for treatment of relapse/refractory multiple myeloma (RR-MM). In Turkey, we have been used the combination of lenalidomide and dexamethasone (RD) for RR-MM patients after 2010. Therefore, we analyzed efficacy and safety of RD in Turkish patients with RR-MM.
Aims: We aimed to evaluate the outcome and the tolerability of the RD in patients with RR-MM who had been treated under the standard clinical practice between October 2010 and June 2016.
Methods: This is a retrospective, single center study. Patients' clinical and laboratory data were collected from patient' files. The overall and progression free survival (OS and PFS) were estimated by Kaplan–Meier methods. Log- rank test was used to evaluate the variables affecting OS and PFS (univariate analysis). Cox proportional hazards regression was used for multivariate analysis to analyze the independent variables affecting PFS and OS.
Results: One-hundred and twenty patients (71 male and 49 female) enrolled in the study. The median age at the start of RD was 64 years (29- 84) and the median number of previous line of treatment was 1 (1- 4). Seventy-two patients (60%) received RD as second-line therapy and 51 of patients (42.5%) treated with autologous stem cell transplantation (ASCT). With regard to the initial dose of lenalidomide, 82 (68.3%) of the patients received the recommended dose of 25 mg per day for 21 days in a cycle of 28 days. Objective response (≥PR) was observed in 87 patients (72.5%); 23 patients (19.2%) achieved CR. The median follow-up was 14 months (range, 1– 72 months), and the median DOR was 19 months (range, 12.4- 25.6 months). Median OS and PFS were 32 months (95% CI, 15.8–48.1 months) and 21 months (95% CI, 15.8- 26.1 months), respectively. In the multivariate analysis, the independent prognostic factors for OS and PFS were treated with previous ASCT, patients who achieved at least PR, patients receiving RD for more than 12 cycles. Adverse events occurred in 69 of patients (57.5%). Hematological and non-hematological adverse events were found at the same rate (n= 47, 39.2%). The treatment discontinuation rate due to AEs was 11.7% (14 patients). The overall incidence rate (IR, events per 100 patient-years) of second primary malignancies (SPMs) was 0.93 (95% CI, 0.04- 4.60). Tha rate of anemia was 12.5% and thrombocytopenia was 9.2% in all grades. Penumania (15.8%), fatigue (14.2%) and herpes infections (0.8%) have been reported as most frequent non-hematological side effects.
Summary/Conclusions: RD is a safe, well tolerated and effective treatment in patients with RR-MM. Good response, previous ASCT and using more than 12 cycles are associated with better survival. Higher OS and PFS and ORR seem to be related to using RD in the first relapse. Adverse events are manageable and lower with prophylaxis.

PB1969

OPTIMIZING THE MANAGEMENT OF NON-HEMATOLOGICAL ADVERSE EFFECTS RELATED TO LENALIDOMIDE IN RELAPSED MULTIPLE MYELOMA PATIENTS. ONE CENTER EXPERIENCE

M. Moya-Arnao[1,*], V. Cabanas-Perianes[1], M.J. Moreno Belmonte[1], M. Berenguer[1], A. Martínez Marin[1], E. Fernandez Poveda[1], R. Pérez López[1], E. Salido Fierrez[1], J. M. Moraleda Jimenez[1]
[1]Hematology, Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain

Background: During many years, the combination of lenalidomide and dexamethasone (Rd) has been an effective treatment for patients with relapsed or refractory Multiple Myeloma (RRMM). On the basis of the available evidence, treatment with Rd may continue in responding patients until progression or unacceptable toxic effects. The data suggest full dose lenalidomide is important for optimal efficacy and to improve the progression free survival (PFS). Approaches to achieve higher doses of lenalidomide could include continuing therapy in responding patients and proactive adverse effects (AEs) management.
Aims: The main aim was to evaluate the incidence of two of most common non-hematologic AEs related to lenalidomide (rash and dystonia) in patients who received treatment with Rd. The second end points were to evaluate the response of rash after switching the enoxaparin to bemiparin and to evaluate the response of the dystonia after treatment with clonazepam, instead of lenalidomide dose reduction.
Methods: We retrospectively reviewed a consecutive cohort of patients with RRMM receiving Rd (R: 25 mg on days 1 through 21. d: 40 mg on days 1, 8, 15, and 22) in 28-day cycles until progression or unacceptable adverse effects, from 2011-2016. All patients received thromboprophylaxis with low-molecular-weight-heparin (LMWH) (Enoxaparin 40 mg subcutaneous daily) the first 4 cycles; thereafter, patients were switched to aspirin 100 mg in a day prophylaxis. Bemiparin 7500 anti-Xa IU once-daily dose was employed if enoxaparin was suspended. Clonazepam dose to treat dystonia was 0,5 mg twice daily. Data were analyzed with SPSS statistical v 22.0.
Results: Between 2011 and 2016 a total of 65 patients received Rd in our center. Baseline characteristics are shown in Table 1. Patients received a median of 2 previous regimens (range 1-6). 51,5% of the patients had undergone one previous autologous stem-cell transplant (ASCT). Rash occurring in 12,3% of patients (grade 2), all of them were concurrently reciving enoxaparine. All rashes resolved switching the enoxaparine to bemiparine, maintaining same dose of lenalidomide. Neither treatment with esteroids or antihistaminic were administrated. Dystonias were reported in 23,1% of patients (grade 2), all of them dissapeared after treatment with clonazepam without lenalidomide dose reduction.

Table 1.

BASELINE CHARACTERISTICS	
Median age (range) — yr	70,5 (38-90)
Gender (M/F) %	45 / 54
Myeloma type (IgG/IgA/IgD/BJ) %	56 / 23 / 5 / 16
Disease stage according to International Staging System — (%) I / II / III	29 / 37 / 34
Adverse Cytogenetic [delp53, t(4;14), t (14;16)] Yes (%)	17%

Summary/Conclusions: Rash and dystonias are frequent adverse effects of immunomodulatory drugs (IMiDs), particularly lenalidomide, often leading to treatment discontinuation and decreasing the potential benefits to patients. According to our data, the rash could be due to synergism between enoxaparin and lenalidomide. In most cases, switch LWHM letting not to reduce lenalidomide dose in order to optimize the benefit of the treatment. Clonazepam, a benzodiazepine, is useful to treat dystonias related to lenalidomide.

PB1970

PROLONGED THROMBOPROPHYLAXIS IN PATIENTS TREATED WITH LENALIDOMIDE AND DEXAMETHASONE DOES NOT SEEM STRICTLY MANDATORY TO PREVENT LATE THROMBOTIC EVENTS

C.S. Cartia[1,*], S. Mangiacavalli[1], V.V. Ferretti[1], F. Cocito[1], M. Ganzetti[1], E. Fugazza[1], B. Landini[1], M. Catalano[1], M. Cazzola[1], A. Corso[1]
[1]Hematology, IRCCS Fondazione Policlinico San Matteo, Pavia, Italy

Background: Risk of venous thromboembolism (VTE) in general population is 1% annually, significantly higher in oncologic setting, in particular with Multiple Myeloma (MM). Treatment with Lenalidomide plus Dexamethasone represents an additional risk factor for VTE, with most of VTE events observed in the first six months since therapy starting. No definitive data are available on the more appropriate duration of thromboprophylaxis (TP) in patients treated with lenalidomide.
Aims: To explore: I) the incidence of late thrombotic events in a real world population of relapsed MM, addressed to Lenalidomide plus low dose Dexamethasone treatment (Len-dex), and concomitant TP with low molecular weight heparin (LMWH) performed for the first 4-6 months of therapy, without TP maintenance, II) the possible correlation between the presence of thrombotic risk factors and the occurrence of a late VTE.
Methods: We performed a retrospective analysis, after regular approval of local ethic committee, on chart data of 103 patients (pts) with relapsed MM treated with Len-dex according to label indication between January 2003 and December 2016 at our single centre institution. VTE prophylaxis was performed with daily dose of subcutaneous LMWH 4000 IU for 4-6 months, with no further TP, regardless the presence of thrombotic risk factors.
Results: Main features of patients on study were: median age 66.3 years (range 41.9-85.2 years), median previous line of therapy 3 (range 1-7), time from diagnosis to lenalidomide starting 33.3 months (range 0.3-159.9 months), median duration of Lenalidomide treatment 8 months (range 0.4-65.2 months) with the following response: ≥PR 56%, CR 7%. Table 1 shows type and distribution of risk factors for VTE. In details median number of VTE risk factors per patient was 2 (range 0-6), 58.2% of pts had ≥2 risk factors, 41.8% of pts (43 pts) had 0-1 risk factor for VTE. Median duration of TP is 4.8 months (range

0.4-6 months). No hemorrhagic events were observed during LMWH. Cumulative incidence of VTE was 11.7% (12/103 pts), similar to that previously reported in the literature in patients with continuous TP. The median time from lenalidomide starting and VTE occurrence was of 12.2 months (range 1- 88.2 months), with only one patient developing early VTE among our group. In detail we observed 10 deep vein thrombosis (83%), 1 pulmonary embolism (8.5%), 1 myocardial infarction (8.5%). Most of patients developing VTE had good disease control (≥PR 83%, 10 pts). Concomitant adverse events (AE) was registered in 41.7% of pts (5/12). Most common concomitant AE were infections of respiratory tract (3 pts) and gastrointestinal AE (2 pts). The median number of risk factors for VTE in patients developing or not thrombosis was similar (2.5 *vs* 2, p=0.092).

Table 1. Baseline distribution of risk factors for thrombosis in the population on study.

Risk Factor	absolute number	Percentage (%)
Age >65	54	52.4
Obesity	10	9.7
CVC/Pacemaker	2	1.9
Immobilization	8	7.8
Trauma	1	1
Surgery	7	6.8
Erythropoietin	25	24.3
Chronic renal failure	16	15.5
Cardiopathy	44	42.7
Light chain disease	3	2.9
Acute Infection	14	13.6
Diabetes	11	10.7
Previous VTE	11	10.7

Summary/Conclusions: This study shows that LMWH is effective and well tolerate for early VTE prophylaxis during Lenalidomide plus low dose Dexamethasone. Incidence of late VTE without TP maintenance is similar to that reported with long-term antiplatelet therapy. We found no difference in factors predisposing for thrombosis among patients developing or not VTE, with a not negligible proportion of concomitant adverse events observed nearby VTE occurrence.

PB1971

ELDERLY PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE REAL WORLD

E. Yamazaki[1,2,*], H. Takahashi[2], D. Ishibashi[3], K. Kishimoto[3], K. Miyashita[4], A. Numata[5], Y. Hattori[6], R. Kawasaki[7], H. Koharazawa[8], K. Fujimaki[6], J. Taguchi[8], H. Fujita[3], R. Sakai[5], S. Fujisawa[4], H. Harano[9], H. Nakajima[10]
[1]Clinical Laboratory Department, Yokohama City University Hospital, [2]Department of Hematology and clinical Immunology, Yokohama City University School of Medicine, [3]Department of Hematology, Saiseikai Yokohama Nanbu Hospital, [4]Department of Hematology, Yokohama City University Medical Center, [5]Department of Medical Oncology, Kanagawa Cancer Center, Yokohama, [6]Department of Hematology, Fujisawa City Hospital, Fujisawa, [7]Department of Hematology / Oncology, Yamato Municipal Hospital, Yamato, [8]Department of Hematology, Shizuoka Red Cross Hospital , Shizuoka, [9]Department of Hematology, Yokosuka City Hospital, Yokosuka, [10]Department of Hematology, Yokohama City University School of Medicine, Yokohama, Japan

Background: Many new agents for multiple myeloma (MM) were launched during the last decade, and the clinical trial using such new agents showed promising results for MM patients. However, clinical course of elderly patients with newly diagnosed MM (NDMM) in the real world is different from the results of clinical trial.
Aims: We examined the clinical parameter to assess survival in elderly patients with NDMM in clinical practice.
Methods: We performed a retrospective study involving 125 elderly NDMM patients from April 2012 to September 2015. Patients aged 60 years or older, who were ineligible for autologous stem cell transplantation, were selected. The study included 57 males and 68 females, with median age at diagnosis of 74 years (range, 60-95 years). ECOG performance status at diagnosis were 0-1, 67; 2-4, 58. We collected pretreatment parameter at diagnosis as follows; monoclonal protein type (IgG,60; IgA,32; IgD,1; BJP,30; non-secretary,2), light chain (kappa, 72; lambda, 52; unknown 1), hemoglobin level (mean 8.9 g/dL [range 5.8-15.2]), estimated glomerular filtration rate (eGFR) (mean 49.3 mL/min [range 3.6-114.2]), calcium level (mean 10.0 mg/dL [range 8.7-20.2]), albumin level (mean 3.4 g/dL [range 1.0-5.3]), beta-2-microglobulin (mean 5.1 mg/L [range 1.6-51.5]), involved:uninvolved serum free-light chain (FLC) ratio (mean 143.8 [1.83-21133]), cytogenetic abnormalities by using fluorescence *in situ* hybridization (FISH) [none, 53; t(4;14), 7; del(17p), 14; t(4;14) & del(17p), 5; t(4;14) & t(14;16) & del(17p), 1].
Results: Of 125 patients, 76 patients received bortezomib based therapy (VMP, 49; VD, 21; VCD, 6), 6 patients received lenalidomide based therapy (Ld, 6), 10 patients were received MP therapy, 19 patients received dexamethasone therapy (high dose, 16; low dose, 3), 1 patient received radiation therapy as first line therapy, and 13 patients received only supportive care due to their fragility. After induction therapy, the overall response rate (at least partial response, PR) was 52.7% (stringent complete response (sCR) 0.3%, CR 4.5%, very good PR 16.1%, PR 29.5%). Overall survival (OS) was 74.5% at 1 year, 66.2% at 2 years with median follow-up of 19 months (range 1-52) for patients who were still alive at the date of last contact and 14 months (range 1-52) for entire cohort. Death occurred in 41 patients during the follow-up period. International staging system (ISS), with ISS1, 19; ISS2, 42; ISS3, 60; N/A, 4, can divide elderly patients into three distinct survival groups (P <0.001) (Figure 1A). Univariate and multivariate analysis showed a lower OS was associated with eGFR lower than 40 ml/min (HR 2.279, 95%CI 1.152-4.510) (Figure 1B) and serum calcium level greater than 11 mg/dL (HR 3.036, 95%CI 1.412-6.529) (Figure 1C). Among 80 patients with FISH data, survival of those with t(4;14) or del(17p) or t(14;16) was not statistically different (P=0.394). Survival of patients treated with bortezomib or lenalidomide as an induction therapy was better, while not statistically significant (P=0.066) than those who ware not.

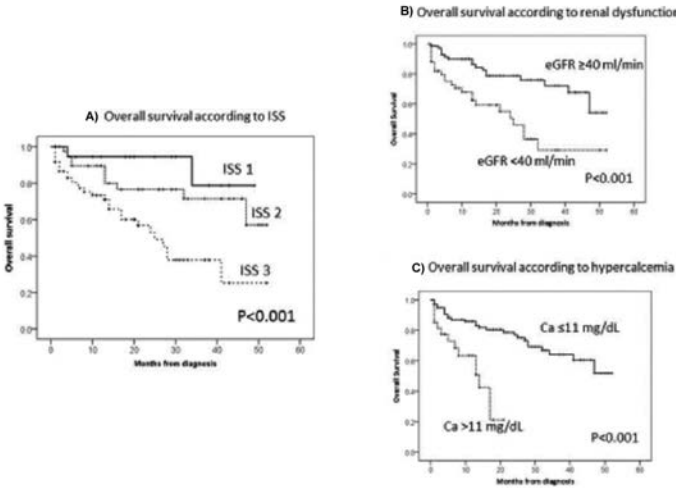

Figure 1.

Summary/Conclusions: Renal dysfunction and hypercalcemia at diagnosis is predictive of poor OS for elderly NDMM patients in real world.

PB1972

RETROSPECTIVE ANALYSIS OF 121 MULTIPLE MYELOMA PATIENTS USING THE R-ISS PROGNOSTIC STAGING SYSTEM AND RESPONSE TO FIRST LINE OF TREATMENT

R. Ghonema[1,*], S. AlShemmari[1], R. Pandita[1], M. Hasaneen[1], M. Al-Drees[1]
[1]Hematology, Kuwait cancer control centre, Kuwait, Kuwait

Background: The International Myeloma Working Group has developed the R-ISS (Revised International Staging System) as a simple and powerful prognostic staging system. We collected the LDH level and the cytogenetics of a group of patients and studied the difference between the ISS (International Staging System) and the R-ISS (Revised International Staging System) for those patients.
Aims: To evaluate and compare between the ISS and the R-ISS for a group of patients treated in Kuwait Cancer Control Centre.
Methods: A retrospective analysis of the data collected from 121 patients registered as multiple myeloma from 2011-2015, 5 of the patients presented to our centre after initial work up and starting the treatment abroad. The patients were categorised according to age, gender, ISS stage, R-ISS stage, first line therapy and response.
Results: We recognised increase of the number of the yearly diagnosed patients with myeloma 2.48% of patients the actual date of diagnosis was before 2011 but they presented to our centre from2011-2015. Median age of patients at presentation is 56 years old , 3.33% between30-40 years old, 18.33% between 40-50 years old , 35% between 50-60 years old , 31.67% between 60-70 years old and 11.67% between 70-80 years old. Male to female ratio 1.75:1 (Table 1). According to ISS stage patients were categorised into14% stage I, 31% stageII, 47% stage III. Restaging using the RISS revealed10% stage I, 26% stageII, 56%stage III. Almost half of our patients are diagnosed in the third stage, and more patients were shifted from stage I or II were categorised in the third stage due to either high LDH level, high cytogenetic risk or

even both. First line treatment 55% of the patients received Bortezomib based triple therapy, 22% received CTD (Cyclophosphamide, Thalidomide, Dexamethasone), 7% RD (Lenalidomide, Dexamethasone), 3% CyBorD (Cyclophosphamide, Bortezomib, Dexamethasone), 3%RV (Lenalidomide, Bortezomib), 2% Thal-Dex (Thalidomide, Dexamethasone), 2% RT (local Radiotherapy), 2% WatchfulWait,1% MP (Melphalan, Prednisone) and 3% refused for treatment and lost follow up.

Table 1.

ISS stage	% of patients	RISS stage	% of patients
Stage I	14%	Stage I	10%
Stage II	31%	Stage II	26%
Stage III	47%	Stage III	56%
Plasmacytoma	2%	Plasmacytoma	2%
MGUS	2%	MGUS	2%
Unknown stage(diagnosed outside our centre)	4%	Unknown stage(diagnosed outside our centre)	4%

Summary/Conclusions: Applying the RISS system to myeloma patients is very effective and easy method to categorise myeloma patients, a significant number of patients in Kuwait are diagnosed as stage III, with median age of 56 years although the use of novel therapies shows excellent response to most of them.

PB1973

FEASIBILITY/PHASE II STUDY OF MYELOABLATIVE BEAM ALLOGENEIC TRANSPLANTATION FOLLOWED BY ORAL IXAZOMIB MAINTENANCE THERAPY IN PATIENTS WITH HIGH RISK MYELOMA

E. Scott[1,*], R. Maziarz[1], S. Dreumont[1], C. Gasparetto[2]
[1]Hematology and Oncology, Oregon Health and Science University, Portland, [2]Hematology and Oncology, Duke University, Durham, United States

Background: While the role of allo-HCT in MM remains controversial several studies have shown encouraging PFS and OS with this treatment even in patients with high-risk myeloma (HRM). HRM manifests with early relapses and refractoriness. Median OS is 2.5 years despite aggressive therapy with novel agents. Post auto-HCT maintenance with lenalidomide is considered standard of care, but post allo-HCT maintenance presents unique challenges and has not been well studied. Ixazomib (Ixa) is a new oral proteasome inhibitor with activity in bortezomib resistant patients, and is a promising agent in the maintenance setting.
Aims: Here we present preliminary results for this trial. The primary objective is safety defined as day 100 transplant related mortality (TRM), and safety of Ixa maintenance (incidence of grade III-IV GvHD and Ixa related toxicity). Other objectives include determination of efficacy (ORR, PFS, MRD for CR), the ability to start Ixa, and quality of life.
Methods: The protocol was approved by a local institutional review board and ethics committee. The study was conducted in accordance with the Declaration of Helsinki. All subjects provided written informed consent prior to treatment. Eligibility criteria include: age ≤65; relapsed MM previously treated with auto-HCT, bortezomib and an immunomodulatory agent; one of the following high-risk criteria: deletion (del)17p, t(4;14), t(14;16), t(14;20), amp1q gain or del1p, del13q by conventional karyotyping, hypodiploidy, high-risk GEP, B2M >5.5mg , plasmablastic morphology (>2%), or relapsed plasma cell leukemia; 8/8 HLA matched unrelated (MUD) or sibling donor. The BEAM conditioning regimen includes: BCNU 300 mg/m^2 on day -6; cytarabine 400 mg/m^2 daily day -5 to day -2; etoposide 200 mg/m^2 daily day -5 to day -2; melphalan 140 mg/m^2 on day -1. Oral Ixa 4mg on days 1 and 14 of a 28-day cycle. Ixa may start between day 100 and 180 post HCT, and continue for up to 24 cycles.
Results: Six subjects were enrolled, 3 at OHSU and 3 at Duke, from Sept 2015 to Dec 2016. Median age of 51 (range 46-57), 2 female, and all of white race. High risk factors: del17p, del17p+t(14;16), del17p+amp1q+del1p, del13q+amp1q, amp1q, plasmablastic morphology (>2%). At study entry 2 subjects were in VGPR, and 4 in PR. Three subjects received 8/8 HLA matched MUD, and 3 received sibling donor HCT. GvHD prophylaxis with tacrolimus and methotrexate was given in 3 subjects with the addition of methylprednisone in 3 subjects. Two subjects started Ixa (at day 139 and 128) and remained on therapy for 198 and 59 days respectively; both discontinued for disease progression. Three subjects remain on study, and have not started Ixa. At day 100 post HCT, 4 of 6 subjects were evaluable for response. All had a deepening of response; 3 VGPR, 1 CR. One subject died from BEAM-allo related complications; namely acute stage 4 GvHD (skin and gut), and disseminated adenovirus infection (day 62). Grade 3/4 adverse events include: febrile neutropenia(3); colitis(1); epididimytis(1); mucositis(4); pancreatitis(1); pulmonary edema(2); diarrhea(3); infection(4); staph bacteremia(2); E coli bacteremia(1); adenovirus viremia(1); neutropenia(4); thrombocytopenia(4); acute GvHD(1). Ixa related toxicities include grade 3 neutropenia(2), thrombocytopenia(1), pneumonia(1), nausea and vomiting(1).
Summary/Conclusions: Although this is very early data, it is the first clinical trial to report the use of BEAM conditioning followed by Ixa maintenance for relapsed HRM. Thus far stopping rules have not been met, with expected toxicities occurring.

PB1974

EPIDEMIOLOGY OF MULTIPLE MYELOMA. THE GRANADA MYELOMA REGISTRY

R. Ríos Tamayo[1,*], D. Sánchez-Rodríguez[2], J. Sainz Pérez[3], J.J. Jiménez Moleón[4], M.J. Sánchez Pérez[5], M. Jurado Chacón[1]
[1]Hematology, University Hospital Virgen de las Nieves, [2]Hematology, FIBAO, [3]Hematology, GENYO, [4]Medicine Preventive, University of Granada, [5]Cancer Registry, Andalusian School of Public Health, Granada, Spain

Background: The Granada Myeloma Registry is the second largest single-institution population-based registry (Ríos-Tamayo et al, 2015) of multiple myeloma (MM) referenced to date. Here we update and point out the epidemiological variables of interest.
Aims: To highlight the importance of the epidemiological perspective in the knowledge and outcome of MM.
Methods: From January 1985 to February 2017 all consecutive patients diagnosed with MM at our institution have been registered, including clinical, biological and socio-demographic variables, as previously reported. A comprehensive approach to comorbidity was recorded as well as diagnostic and treatment delay. Overall survival (OS) was estimated by the Kaplan-Meier method.
Results: 700 patients have been included in the registry, 343 men (49%) and 357 women. All cases have their place of residence in the Granada province. The median age was 67 years (range: 12-93). The race was Caucasian in 98.9%. In relation to occupation, 18.4% were skilled or elementary agricultural workers. Only 9% had a previously documented precursor disease (solitary plasmacytoma, monoclonal gammopathy of undetermined significance , or smoldering MM), and 14 patients (2%) remain alive with smoldering MM without progression. The subtype of MM is IgG 55.6%, IgA 24.8%, Light chain Only 15.9%, Non-secretory 3%, IgD 0.6% and IgM 0.2%. The International Staging System is known in 378 patients: 1 (25.9%), 2 (25.7%), and 3 (48.4%). Baseline performance status (ECOG) was: 0 (4.7%), 1 (41.1%), 2 (26.7%), 3 (21.7%), and 4 (5.9%). Comorbidity was assessed in 498 patients. 30.6% of patients were obese at the moment of diagnosis. 8.2% had other previously known or synchronous neoplasm. 150 patients (30.1%) had three or more comorbidities. Median diagnostic delay was 4.1 months (0.1-80) and median treatment delay was 13 days. 44 patients (6.3%) were very unfit and they did not receive active treatment. Information about stem cell transplant is available in 606 cases: 151 of them (24.9%) received a first autologous transplant. Median OS for the whole cohort was 43.1 and 22.4 months for patients younger than 65 years or 65 years and older, respectively (p <0.001). For patients diagnosed in 2010 or later, median OS is not reached for younger than 65 and 40.4 months for the elderly (p=0.001). Information about the main cause of dead is available in 230 patients: 101 (43.9%) of them died by infection.
Summary/Conclusions: MM is a very heterogeneous disease from a clinical, biological and epidemiological perspective. The distribution by sex is identical. Farmer is the most frequent occupation. Almost one in three patients are obese, and one in ten had another prior or associated neoplasm. Infection is the leading cause of death. Information derived from population-based registries may help to complement data from clinical trials.

PB1975

REAL WORLD USE OF IXAZOMIB WITH LENALIDOMIDE AND DEXAMETHASONE FOR PATIENTS WITH RELAPSED AND RELAPSED REFRACTORY MULTIPLE MYELOMA

M. Ziff[1,*], S. Cheesman[1], C. Kyriakou[1], A. Mehta[1], X. Papanikolaou[1], N. Rabin[1], A. Wechalekar[1], K. Yong[1], R. Popat[1]
[1]University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: Ixazomib (Ixa) is a novel oral proteasome inhibitor (PI) approved in combination with lenalidomide and dexamethasone (IRD) for the treatment of relapsed/refractory multiple myeloma (MM). This was based on the TOURMALINE-MM1 trial which demonstrated a progression free survival benefit over RD. However real world use often differs to clinical trials due to heterogeneous patient selection, more flexibility with dosing intensity and country specific prescribing practices/funding restrictions.
Aims: To characterise real word use of IRD by demographics, response rate (RR) and progression free survival.
Methods: This was a retrospective review of patients sequentially treated with IRD at a large UK Haematology Centre. Patients received Ixa 4mg D1, 8, 15 with lenalidomide (dose as per label) days 1-21 and dexamethasone 40mg weekly or as tolerated every 28 days until disease progression or intolerance. In some cases, Ixa was added later to RD. RR and PFS were assessed according to IMW criteria and haematological toxicities graded by CTCAE 4.0 criteria.
Results: Up to 31st October 2016, 30 patients were treated with the IRD schedule. Median age was 65 years (32-75), male (57%), ISS: stage I 18 (60%), stage II 4 (13%), stage III 8 (27%). Patients had a median of 2 (2-5) prior lines of therapy. All patients had previous treatment with a proteasome inhibitor (PI) (29 bortezomib, 5 carfilzomib) and 8 (27%) were refractory to a PI. 3 (10%) had prior lenalidomide and all remained sensitive. 23 (77%) had a prior autol-

ogous stem cell transplant. Out of those with results, 18 (69%) had adverse cytogenetics including 6 (23%) with TP53 loss. The median number of treatment cycles completed was 6 (2-35) with a median time on treatment currently of 5.5 months (1.6-40) for a median follow-up of 6.8 months (1.6-40). 24 patients were evaluable for efficacy analysis. 7 discontinued therapy, 6 due to disease progression of which 5 (83.3%) were refractory to a PI. 1 patient discontinued due to personal choice. The overall response rate (ORR) was 70.8% (PR 13 (54.1%), VGPR 3 (12.5%), CR 1 (4.2%)). For those refractory to prior PI, the ORR was 37.5% (PR 2 (25%), VGPR 1 (12.5%)). 7 (29%) had Ixa added for sub-optimal response (<PR) or PD. 2 had an improvement in response (VGPR and MR); 1 stabilised disease and the rest remained refractory. 5 (21%) had Ixa added whilst responding to RD, with the intention of deepening response and prolonging PFS. All continued to maintain their response. The median overall PFS was 19.23 months. The PFS for those refractory to prior PI was 11.6 months *vs* not reached for those sensitive (p=0.0159). Those with TP53 loss had a median PFS of 7.5 months. IRD was well tolerated with 5 (20.8%) patients experiencing grade 3-4 neutropenia and thrombocytopenia and 1 patient experiencing grade 4 anaemia. This resulted in Ixa dose reductions in 4 (16.7%) patients. Ixa was stopped in 1 patient due to adverse events.

Summary/Conclusions: This real world dataset highlights differences in patients treated in routine practice to trials. No patients were treated at first relapse due to funding restrictions, whereas most in the trial were. Patients had up to 5 prior lines, all had prior PI exposure and a higher proportion were PI refractory (33% *vs* 2%) which correlated with a worse outcome. Nevertheless the overall efficacy of our study (ORR 70.8%; median PFS 19.23 months) was comparable to the TOURMALINE-MM1 trial which had an ORR of 78.3% and median PFS of 20.6 months in the Ixa group.

PB1976

EFFICACY AND TOLERABILITY OF LENOLIDOMIDE AND POMALIDOMIDE IN RELAPSED/REFRACTORY MYELOMA PATIENTS IN A REAL WORLD STUDY

G. Adams[1,*], M. Collins[1], C. Kyriakou[1], R. Ayto[1]
[1]Haematology, Northwick Park Hospital, London, United Kingdom

Background: New agents have revolutionised the treatment of multiple myeloma. Immunomodulatory drugs (IMiD) such as lenalidomide and pomalidomide are potent re-induction drugs leading to improved Progression Free Survival (PFS) and Overall survival (OS). Published studies include exclusion criteria such as cytopenias, renal dysfunction and poor performance status (common in multi-relapsed patients), raising the question regarding the benefit of IMiD therapy in the real-world setting.

Aims: In our study we aimed to describe the real-world experience of the use of lenalidamide followed by pomalidamide rescue in a relatively elderly co-morbid cohort over a 4 year period and compare this to national averages. We reviewed IMiD efficacy, including sequential lenalidomide followed by pomalidomide, together with tolerance.

Methods: Records of delivered chemotherapy cycles were retrieved from local pharmacy data and national averages from Celgene ePAF data. Outcome data collected from clinical notes and laboratory results.

Results: We collected data on 46 patients treated between 2011-2014 with lenalidomide, 17 whom progressed to recieve pomalidomide. The median age at initial myeloma diagnosis was 71 years, with median age at starting lenalidomide 77years (range 36-94). This gave an average of 5 years from diagnosis to commencing lenalidomide (range 1-15 years). Myeloma subtypes included IgG 28/46, IgA 11/46, light chain disease 4/46 and 3 with IgD and non-secretory myeloma. High risk cytogenetics [17p-, t(4:16), t(4:20), hypodiploidy, chromosome 1 abnormalities] were identified in 9/46 and 16/46 were high-risk based on biomarker staging (ISS). All patients had at least 1 preceding line of therapy before starting lenalidomide, average 2 lines (range 1-6). Prior treatment included alkylating agents/steroid duplets, thalidomide combinations, bortezomib-based therapy and autograft. National average for the% of patients reaching cycle 26 was 16% comparing to the local average of 31%. This included patients receiving 5mg due to severe renal impairment or cytopenias. In the patient group between 65-75 years of age, 50% reached cycle 26 compared to the national average of 16%. Average duration on treatment was 15 months. (Local-cohort). Lenalidomide-treatment breaks occurred in 16 patients with a median of 5 months (infection, cytopenias, liver dysfunction, foreign travel, other). Cytopenias or infections were seen in 45% of local patients with 28% of patients having subsequent dose reductions. Based on performance status, renal function and prior drug tolerability, only 30% of patients were prescribed lenalidomide 25mg od. Despite this 17 patients (36%) achieved a prolonged PFS of >20 months and 13/46 (30%) a PFS of >30 months. The longest observed PFS in the local cohort was 53 months. The average number of cycles in those who progressed to pomalidomide was 12.8 (n=17), which is double that of the national average reported in seminal trials. These patients had few treatment breaks and treatment was well tolerated (pomalidomide duplets or triplets).

Summary/Conclusions: We conclude from this real-world retrospective review of 2nd and 3rd line IMiD therapy that these salvage regimes are highly effective. Patients on lenalidomide monotherapy post triplet/duplet induction were often re-escalated back onto dexamethasone and alkylator (IV/oral) based regimes with successful salvage, contributing to the observed long duration of local therapy compared to national averages. Pomalidomide was highly effective at rescuing patients failing lenalidomide-based regimes and well tolerated.

PB1977

APPLICATION OF CONDITIONING REGIMEN WITH BUSULFAN AND CYCLOPHOSPHAMIDE IN AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA

Y. Xu[1,2], C. Fu[1,2,*], Y. Yao[2], W. Yao[2], S. Jin[2], L. Yan[2], J. Shang[2], X. Zhu[2], A. Sun[2], D. Wu[1,2]
[1]Institute of Blood and Marrow Transplantation,Collaborative Innovation Center of Hematology, Soochow University, [2]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Busulfan is the most commonly used drug in conditioning regimens for hematopoietic stem cell transplantation and high-dose melphalan (MEL)is the standard conditioning regimen in autologous stem cell transplantation(ASCT)for multiple myeloma.Studies have shown that in ASCT for multiple myeloma,conditioning regimens containing busulfan is equally effective as HDM.

Aims: Evaluate the safety and efficacy of BUCY(busulfan and cyclophosphamide)conditioning regimen for autologous hematopoietic stem cell transplantation (ASCT) in patients with multiple myeloma (MM).

Methods: We retrospectively analyzed the clinical data of 72 MM patients who received transplantation in the Hematology Department of the First People's Hospital of Soochow University from May 2012 to June 2015. Among them, 36 patients underwent BUCY regimen while the others received high dose melphalan.Those were compared between the two groups including the complication, the hematopoietic reconstitution and the post-transplantation efficacy.

Results: There were no significant differences in age, stage, induction therapy, mobilization method between the two groups.The transplantation-related adverse events were similar in both groups but the incidence of pulmonary infection and bloodstream infection were slightly higher in BUCY group .The median time to neutrophil engraftment in the BUCY and HDM groups were 10(8-17) days *versus* 10(9-13)days, taking the same time on average(P=0.046). On the other hand, the median time to platelet engraftment was 10(8-18) *versus* 11(9-47)days accordingly(P=0.017) The TRM in both group was 2.7%.The SCR/CR rates after ASCT (47.2% and 50.0%) were higher than those before it (38.9% and 26.6%), in both groups.In the BUCY group, the median follow-up was 12.5 (0-26) months. Six patients (16.7%) underwent disease progression.The 2-year progression-free survival(PFS) rate was 68%.Correspondingly,in the HDM group,the median follow-up time was 23 (0-38) months. Fifteen patients (41.7%) developed disease progression and the 2-year PFS rate was 55%.

Summary/Conclusions: The BUCY regimen is a safe and effective therapy for ASCT in patients with multiple myeloma.Besides, BUCY regimen is not inferior to HDM regimen.In conclusion, BUCY regimen may replace HDM regimen as a standard conditioning regimen for ASCT in multiple myeloma.

PB1978

MULTIPLE MYELOMA WITH CENTRAL NERVOUS SYSTEM INVOLVEMENT, 12 CASES AND REVIEW OF THE LITERATURE

G. Varga[1,*], G. Mikala[2], L. Gopcsa[2], Z. Csukly[2], P. Reményi[2], G. Szombath[1], A. Masszi[1], H. Andrikovics[3], G. Balázs[4], B. Tímár[5], T. Masszi[1]
[1]3rd Department of Internal Medicine, Semmelweis University, [2]Department of Haematology and Stem Cell Transplantation, St. István and St. László Hospital, [3]Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, [4]Heart and Vascular Center, Division of Diagnostic Imaging, [5]1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary

Background: Central nervous system (CNS) propagation is a rare event in multiple myeloma (MM), but may become more prevalent as newer treatment options allow patients to have a prolonged life expectancy and with this comes the selection of increasingly aggressive clones.

Aims: We reviewed 12 MM cases with CNS involvement treated in two hospitals.

Methods: Statistical analyses were performed using the SPSS (version 20.0) software package.

Results: Between 2008 and 2015 twelve MM patient developed CNS involvement which presented in all cases at relapse. The median age at diagnosis and at CNS presentation were 55.5 and 57.4 years. At first presentation nine had ISS 3, one ISS 2 and two ISS 1 stage disease, two patient presented originally as plasma cell leukaemia. FISH showed 1q amplification in 4, 13q deletion in 4, translocation (4;14) in 1, t(11;14) together with 17p deletion in 1, hyperdiploidity in 1 and complex karyotype in 2 cases. In 2 cases we demonstrated the development of new karyotypic abnormalities (one 1q amplification, one 17p deletion) at CNS progression. The median number of treatment lines prior to CNS progression was 2 which included bortezomib in all and thalidomide in all but one cases, two patients had lenalidomide. Six patients had ASCT before the CNS progression from which one had a second ASCT and one a reduced intensity allogeneic transplantation. The median time from diagnosis to CNS

progression was 23.9 (3-65) months. Eight patients presented with cerebral nerve palsy, 2 with paraplegia, 1 with hypacusis and 1 with headache. CSF cytospin or flow cytometry was positive in 7, MRI or CT supported the diagnosis in 4 patients. Treatment consisted of combination chemotherapy, intrathecal chemotherapy, cranio-caudal radiotherapy and imids with various success. The PFS and OS from CNS progression was 63 and 125 days. Two patients survived for over a year (427 and 776 days), both responded in terms of CNS symptoms to imid-based combination therapy and one had cranio-caudal radiotherapy (Figure 1).

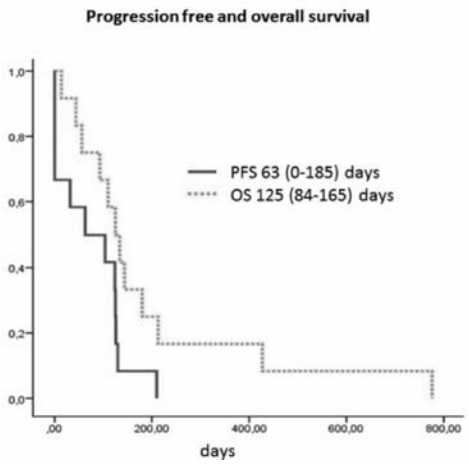

Figure 1.

Summary/Conclusions: CNS progression in MM has a particularly poor prognosis as it represents a late stage of an aggressive relapse which often shows chemo-refractoriness. The differential diagnosis includes infection, autoimmune or vascular diseases of the CNS as well as paraneoplasia and drug toxicity. The CNS penetration of the effective myeloma drugs is poor except for the imids, and drugs with CNS availability are usually not very effective in refractory MM.

PB1979

DARATUMUMAB; CHALLENGES OF INTEGRATING THIS NEW THERAPY INTO STANDARD CARE

L. Little[1,*], R. Powles[1]
[1]Haemato-Oncology, Cancer Centre London, Parkside, London, United Kingdom

Background: Daratumumab (Darzalex) is the first anti-CD38 human Monoclonal Antibody approved for Multiple Myeloma (MM). Targeting the CD38 antigen on the surface of MM cells it causes apoptosis, and has an immune modulated tumour lysis effect. Success in Clinical trials meant that this drug, administered as single agent, or in combination with other novel therapies (Lenalidomide or Bortezomib), received accelerated FDA Approval in the US. It is now being introduced into standard hospital care.
Aims: Daratumumab presents unique challenges to the delivery of risk managed care, due to effects on some blood and bone marrow testing, and to the Infusion Related Reactions (IRRs) seen at the outset of treatment. This poster will highlight important aspects of the treatment pathway for this new therapy, from a single centre perspective.
Methods: We outline the pathways integrated at MDT level; patient characteristics and adverse event profiles of the 15 myeloma patients we have treated with Daratumumab, in a standard service setting.
Results: Daratumumab (Dara) affects certain pathology tests so samples should be clearly identified. Relevant laboratory teams need to be aware of the methods used to process samples. Daratumumab binds to CD38 on Red Blood Cells, and therefore with Cross Match Compatibility testing and Antibody Screening. Obtaining RBC Products for patients receiving Dara will take longer, requiring up to 48 hours' notice. Cross match samples taken prior to treatment provide the National Blood Service Laboratory with a baseline antigen profile to aid selection of suitable blood products. Dara is detected during Paraprotein Electrophoresis; Pre and Post baseline samples help to identify the Darzalex Band in the serum; our lab use a Sebia capillarys 2 analyser to separate the Dara band for accurate reporting. Bone Marrow Testing: Daratumumab affects Immunophenotyping by masking the CD38 epitope used to identify plasma cells by flow cytometry; special kits are available using a different CD38 epitope thus dealing with this issue. Infusion Related Reactions (IRRs) have been reported in over half of patients receiving Daratumumab: 95% of these were seen at the first dose. Typically involving the upper respiratory tract and include rhinitis, cough, wheeze, bronchospasm, laryngospasm and chest pain. More rarely they include rash, fever, and nausea. Reactions can be grade 1-4 so it's important that the patient is closely monitored where there is quick access to specialist staff, resuscitation equipment and respiratory support in a high dependency setting. Staff training is important, and patients made aware that they report all new symptoms so the infusion is interrupted immediately and the IRRS treated and re-started at a lower rate when the symptoms have resolved. Premedication is given one hour prior to infusion and patients with a history of COPD receive extra support. Patient characteristics. Total:15. (Table 1).

Table 1.

Age	Gender	Number of prior treatments	Regimens	Disease outcome
Range:36-81years Mean: 61 years	Male: 8 Female: 7	Range: 2-14 Median: 4	Single agent Dara: 1 Dara with Lenalidomide: 4 Dara with Bortezomib: 1	Response: 14 Progression: 1
1st dose dates	**IRRs Log**	**IRRs seen**	**Grades**	**Infusion duration**
27.7.2016-15.11.2016	IRRs: 14/15 (no IRRs 1). Total completed: 13 Total aborted: 2 (*both successfully re-challenged at second dose).*	Common: Nasal congestion. Rhinitis. Throat irritation. Cough. bronchospasm. Chest pain. dyspnoea. Rare: Rash, nausea. Fever, hypotension.	1-3	Range: 6hr30 - 10hr55. Mean: 8hr39 1 aborted at 65mins 1 aborted at 10hrs

Summary/Conclusions: Education, to include Blood Transfusion, Protein and Histopathology laboratory, and High Dependency Unit staff, in the key aspects of monitoring and risk management are an important part of integrating this new therapy to the treatment pathway for myeloma patients. Daratumumab is likely to become an important treatment for improving both Outcomes and Quality of Life for Myeloma patients going forward.

PB1980

MULTIPLE MYELOMA IN HIV+ PATIENTS LITERATURE REVIEW AND OWN CASE

A. Leyghton[1,2,*], A. Pivnik[1], M. Tumanova[1], G. Dudina[1], E. Sergeeva[1]
[1]Oncohematology, MKNC, [2]Internal Medicine, RUDN, Moscow, Russian Federation

Background: Multipe myeloma (MM) and HIV infection in AIDS stage until now its considered not to be associated. Recently new ideas appear in the literature such as influence of HAART on the treatment outcomes of MM in HIV negative patiens.
Aims: To find literature sources on multiple myeloma in HIV positive patients and elucidate the problem of this association. evaluate the impact of HAART in multiple myeloma.
Methods: Patients were retrospectively identified out of 39 cases of MM and HIV from Pubmed/Medline from 1983 to 2017, and own case reported.
Results: Patients with MM and HIV infection did not differ significantly from the MM in HIV-negative with respect to age, gender, stages and renal function. Effects of HAART on levels of serum M-protein HAART itself has been reported to decrease M-protein in an HIV+ patient with MM. We determined whether HAART alone, in the absence of MM treatment, had any effects on the level of serum M-protein in HIV+MM patients. Depending on the interval between the discovery of the HIV infection HAART treatment initiation, and the diagnosis of MM and initiation of its treatment. The overall and progression-free survival of HIV+ MM patients on HAART appeared to be superior to that of HIV-negative MM patients. The survival of the HIV+ MM patients were also superior to that of non-HIV MM patients reported in the literature. The majority of HIV+ MM patients who had long-term follow-up in our study did not show clinical symptoms of MM and were free of serum-M protein after primary MM therapy in the presence or absence of HAART and maintained treatment with HAART alone. Although MM is not an AIDS-defining illness, meta-analyses of large population studies reveal an increased risk of MM in HIV/AIDS patients. HIV infection is commonly associated with B cell hyperproliferation, as indicated by polyclonal hyperglobulinemia and the development of various autoantibodies. This is presumed to be usually due to these CD4 deficient patients' inability to control Epstein-Barr virus infections, which immortalize B cells. This may help to explain the increased incidence of MM in HIV+ patients. However, HIV can neither infect B lymphocytes or plasma cells, nor drive their malignant transformation. Some authors are going to treat multiple myeloma in HIV seronegative patients with HAART in combination with chemotherapy (Geling Lia and co-authors, Leukemia Research, 2014). A 38 year-old Russian male presented at the Moscow clinical Center in 2015 with pronounced ossalgya and inability to move. Total protein 135 g/l with 81.7 g/l of IgG-k M-protein and no presence of Bence Jones protein. Bone skeletal survey showed multiple generalized lytic lesions. Bone marrow aspirate and biopsy showed 46% plasma cells. Serum creatinine – 104 mkmol/l. HIV and hepatitis C (genotype 1a) screening test were positive, confirmed with Western blot analysis. The CD4 count was 290 cells, HIV viral load 1500 copies/ml, hepatitis C viral load 14,2 mln copies. He was started on HAART, combined with chemotherapy 5 courses of CP+CVP+MP and 7 V-MP. In 2017 total serum protein– 97,3 g/l, M-protein 31,2 g/l, serum creatinine 63,0 mkmol/l. Now he is active without any bone pain receives Pegasis and lamivudine (Table 1).
Summary/Conclusions: Patients with MM and HIV infection did not differ significantly from the MM in HIV-negative with respect to age, gender, stages and renal function, and treatment with addition of HAART.Recently was reported that HAART itself may reduce and even remove m-gradient in HIV positive

patients. It is considered to include HAART in HIV negative patients with MM.The problem of MM and HIV/AIDS association remains unclear and needs to be elucidated.

OPTIMIZATION OF APPROACHES FOR STEM CELL MOBILIZATION FOR AUTOLOGOUS STEM CELL TRANSPLANT FOR MULTIPLE MYELOMA: PRACTICAL CONSIDERATIONS

O.-L. Lee[1,2,*]
[1]Haematology, Royal Adelaide Hospital, [2]Haematology, SA Pathology, Adelaide, Australia

Background: Autologous stem cell transplant (ASCT) is a well-established treatment for myeloma. However, the optimal strategy for stem cell mobilization remains undefined. The goal of mobilization is to collect adequate stem cells for at least 2 ASCT ($4x10^6$/kg), with the minimum apheresis sessions and toxicities such as febrile neutropenia.
Aims: We aim to compare stem cell mobilization using granulocyte colony stem cell factor (GCSF) only (steady state), high dose cyclophosphamide (4 g/m2) with GCSF or low dose cyclophosphamide (2 g/m2) with GCSF.
Methods: We performed a retrospective analysis of 79 patients mobilized with GCSF only from mid-2014 to Aug 2016 with 32 patients mobilized using high dose cyclophosphamide and 23 patients with low dose cyclophosphamide during a similar period.
Results: Patients undergoing steady state collection required a median of 2 days for adequate collection, in comparison to 1 day for both high and low dose cyclophosphamide. Addition of pleraxifor was required in 27.8% of patients on steady state collection, in contrast to 3.1% and 13% of patients on high and low dose cyclophosphamide respectively. The mean yield of CD34+ x 10^6/kg cells collected was 5.39, 9.14 and 8.5 for steady state, high and low dose. There was no significant difference in time to engraftment despite a lower dose of CD34+ cells reinfused for the steady state cohort. Admission for febrile episodes was observed in 50% of patients mobilized with high dose cyclophosphamide, as compared to 13% of patients on the lower dose regime and none in the steady state cohort. Patients mobilized with cyclophosphamide had a longer interval between stem cell collection and transplant (median of 20, 42 and 34 days respectively for steady state, high dose and low dose). However, we observed that 60.7% patients with steady state mobilization had increases in their myeloma markers during this period, in contrast to biochemical improvement in 50% of patients mobilized with high dose cyclophosphamide and 26% with low dose cyclophosphamide.
Summary/Conclusions: All 3 strategies for stem cell mobilization have their own merit. Steady state mobilization is safe and yields sufficient stem cells; however, patients require more apheresis sessions. Moreover, more than a quarter require additional therapy with plerixafor. Of concern, greater than half of these patients have increased myeloma markers during the interval between stopping chemotherapy and mobilization which may potentially affect outcomes. Mobilization with high dose cyclophosphamide yield more CD34+ cells but with increased toxicities- 50% of patients required admission for febrile episodes. Conversely, half of these patients had improvement in their myeloma markers. The use of low dose cyclophosphamide for mobilization resulted in lower admission rates (13%), however, pleraxifor is required in a fraction.
In light of these findings, we propose that patients who have not achieved at least VGPR should be mobilized with cyclophosphamide, the dosage dependent on their individual risks.

PB1982

MINIMAL RESIDUAL DISEASE MONITORING IN MULTIPLE MYELOMA PATIENTS BY FLOW CYTOMETRY: A SINGLE CENTER EXPERIENCE

S. Sizikova[1,*], N. Pronkina[2], E. Batorov[3], G. Ushakova[1], V. Sergeevicheva[1], A. Gilevich[1], I. Kruchkova[1]
[1]Hematology and bone marrow transplantation, [2]Laboratory of immunology, [3]Laboratory of cell immunotherapy, Research Institute for Fundamental and Clinical Immunology, Novosibirsk, Russian Federation

Background: Multiple myeloma (MM) is a malignant disease characterized by an increased number of clonal (abnormal) plasma cells in the bone marrow (BM). High-dose chemotherapy followed by autologous peripheral blood stem cell transplantation (SCT) is used for the treatment of young MM patients and produces a high rate of complete remissions (CR). Recent trials with novel agent combinations alone have also resulted in high CR rates, even among old patients, high-risk patients and relapse/refractory MM. Unfortunately, most patients have a recurrences of the disease. This is due to the persistence of residual tumor cells, known as minimal residual disease (MRD), responsible for tumor relapse.
Aims: BM samples from 51 MM patients who had achieved partial or complete response or were resistant after chemotherapy, including autologous SCT, were evaluated by multiparameter flow cytometry (MFC). The study was conducted to assess the quality of remission, the correlation between the number of abnormal plasma cells of BM and other signs of disease activity, readiness of patients for autologous SCT.
Methods: The study included 51 patients MM, average age - 54 years (36-70 years), who underwent assessment of MRD from November 2014 to February 2017. According to the classification Durie-Salmon the vast majority of patients (n=40) had III stage of disease, 8 patients – II and 2 patients – I. Response to treatment was assessed according to standard EBMT criteria At the time of MRD assessment 20 patients were in CR, 8 had a partial response (PR) and 15 had a resistant disease; 5 patients had a primary MM, 3 patients were in the first relapse. Most of the patients were underwent high-dose chemotherapy with autologous SCT (n=42). Re-evaluation of MRD after therapy was managed to hold in 36 patients at a mean of 3,1 months (1,9-5,7, min-max). Analysis was performed using a FACSCantoII flow cytometer (BD) and FACSDiva software (BD). Instrument performance was checked daily by recording fluorescence intensity with calibrating beads (Cytometer Setup and Tracking from BD Biosciences). Whole BM was estimated using combination of surface and intracellular staining CD38/CD56/CD27/CD117/CD81/CD19/CD45/cytLambda/CD138/cytKappa. The sensitivity of our panel MRD is 0.01% (*i.e.* 10^{-4}).
Results: Among patients in CR (n=20) confirmed the absence of MRD in 6 patients, but 14 CR patients were MRD positive. MRD was detected in all patients with PR and resistant disease (n=31). The relative content of abnormal plasma cells in CR patients with MRD positive (n=14) was significantly lower than that in PR/resistant patients (n=31): 0.095% (0,026-0,271%) *versus* 1,3% (0,203 -5,9%), pU=0,000092. PR patients (n=8) had a lower relative content of abnormal plasma cells (as expressed tendency), than patients with resistant disease (n=15): 0,286% (0,177-1,129%) *versus* 1,48% (0 , 90-8,0%), pU=0,053. Besides the relative content of abnormal plasma cells in PR/resistant patients (n=31) correlated with the serum M-gradient concentration (r_s=0,42; p=0,019) and bone marrow plasma cells (r_s=0,54, p=0,0017).
Summary/Conclusions: Currently, we can conclude that MFC could be considered as the method of choice for MRD monitoring in MM. If the disease is measured, then, indeed, enough to evaluate only the M-gradient level of serum. If the M-gradient is not defined, it is necessary to assess the number of abnormal plasma cells in the BM and strive for the high-quality responses at the time of transplantation. And also it can help us to regulate duration of maintenance therapy.

PB1983

AUTOLOGOUS STEM CELL TRANSPLANTATION IN ELDERLY MULTIPLE MYELOMA PATIENTS

M. Staderini[1,*], C. Nozzoli[2], E. Antonioli[1], I. Donnini[2], I. Cutini[2], A.S. Guarrera[1], M. Di Gioia[1], A. Gozzini[2], S. Guidi[2], A. Bosi[1], R. Saccardi[2]
[1]Hematology Department, [2]BMT Unit, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Background: Autologous stem cell transplantation (ASCT) is currently approved as a "gold standard" first line treatment for multiple myeloma (MM) patients (pts) under 65 year old but the procedure could also be considered feasible in fit elderly patients based on several retrospective studies.
Aims: The aim of our study was to retrospectively evaluate the tolerability and the efficacy of high dose chemotherapy followed by ASCT in selected ≥65 year old MM population.
Methods: We retrospectively analyzed consecutive MM pts aged 65 or older who underwent upfront ASCT at our institution from January 2009 to November 2016. Each patient received induction therapy including proteasome inhibitors and/or immunomodulatory drugs (bortezomib and/or thalidomide based), followed by high-dose cyclophosphamide plus G-CSF and subsequently underwent peripheral blood stem cells (PBSC) collection.

Results: Overall we analized 35 pts: 21 males and 14 females (median age 66, range 65-70); 23 had IgG MM, 4 had IgA MM and 8 had light chain MM. Induction therapy was bortezomib-based (bortezomib in combination with dexamethasone, VD, in 7, or VD plus thalidomide in 26 pts) for a median of 4 cycles (range 3-6), 2 patients received thalidomide plus dexamethasone (6-12 cycles). PBSC were collected after high-dose cyclophosphamide (2 g/sqm in 2 pts, 3 g/sqm in 11 pts, 4 g/sqm in 22 pts) plus G-CSF; plerixafor was administered in 4 pts. Three pts also received lenalidomide and dexamethasone to improve the depth of response before ASCT. At the time of conditioning, among 34 evaluable pts, 8/34 pts were in complete response/stringent complete response (CR/sCR), 19/34 in very good partial response (VGPR), 5/34 in partial response (PR) and 2/34 in stable disease (SD). The conditioning regimen consisted of melphalan 140 mg/sqm in 11 pts or 200 mg/sqm in 24 pts. A median number of 4.11 x10^6 CD34+ cells/Kg was reinfused (range 2.09-10.44). The most frequent complication was fever (9 pts) with gram negative bacteremia documented in 3/9 and gram positive bacteremia in 1/9. Other complications were represented by 1 case of atrial fibrillation and 3 cases of pneumonia and 1 case of VZV reactivation. All 35 pts achieved neutrophils recovery after a median of 12 days (range 8-25) and platelets recovery after a median of 13 days (range 8-45) after transplant. No grade 3-4 toxicities were recorded. No transplant-related mortality was recorded within 100 days post transplantation. Three months after ASCT, among 28 evaluable pts, 10/28 pts were in CR, 14/28 pts in VGPR and 4/28 pts in PR. Three pts underwent tandem ASCT. After a median follow-up of 32 months (range 3-96) among 33 evaluable pts, 20 experienced disease relapse and 7 deaths occurred. Median PFS and OS were 21 and 40 months.
Summary/Conclusions: Our data support the use of ASCT as an effective and safe first-line treatment approach also in elderly MM pts. A careful patient selection is needed to reduce the toxicity of the procedure.

PB1984

EVOLUTION IN THE INCIDENCE OF MONOCLONAL GAMMOPATHIES IN A SOUTHERN SPAIN TERTIARY HOSPITAL IN THE LAST THIRTEEN YEARS

J.M. Maesa[1,*], P. Menenez-Valladares[1], J.L. Garcia de Veas-Silva[2], N. Barbosa[3], R. Duro[4], C. Bermudo-Guitarte[1]
[1]Clinical Biochemistry, Virgen Macarena University Hospital, Sevilla, [2]Immunology, Complejo Hospitalario Universitario de Granda, Granada, [3]The Binding Site, Barcelona, [4]Hematology, Virgen Macarena University Hospital, Sevilla, Spain

Background: Monoclonal gammopathy (MG) is the most common plasma cells disorder. It affects around 3% of the population older than 50 years. The great majority of MG are monoclonal gammopathies of undetermined significance (MGUS), which is a premalignant disorder defined to present less than 3 g/dL of serum monoclonal protein, less than 10% of clonal bone marrow cells and absence of end-organ damage. MGUS is easily detected in laboratory tests and should be monitored because 1% of MGUS per year progress to Multiple Myeloma (MM). Incidence of MGUS and MM is not always easy to determine, but there is a general perception of an increasing incidence that can be attributed to different causes. One is the aging of the population. Another reason is the contribution of clinical laboratories, which count on new determinations (free light chains) or improved techniques in electrophoresis, nephelometry or immunofixation, allowing them to support the diagnose of MGUS that years before remained undiagnosed.
Aims: The aim of this study is to determine the incidence of MGUS, MM and its different types in the reference population of a tertiary hospital in southern Spain between 2003 and 2015.
Methods: In a retrospective study, we determined the total number of MG and its different types diagnosed in our hospital between 2003 and 2015. We calculated the incidence per 100.000/year of MGUS and MM, with 95% confidence intervals. Our reference population, in 2015, was 480.851.
Results: Results in Figure 1.

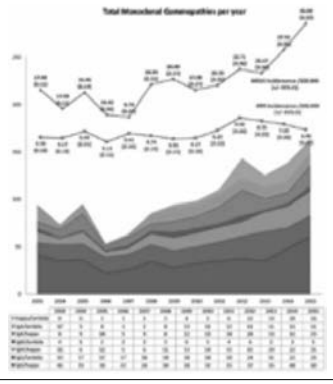

Figure 1.

Summary/Conclusions: The aging of population and the higher sensitivity of laboratory techniques for diagnosing of MG is reflected in the incidence of MGUS, which increased from 17.04 cases per 100.000 in 2003 to 35.00. MM incidence in our area did not increased in parallel.

PB1985

CHARACTERIZATION OF A SERIES OF PATIENTS WITH PLASMA CELL LEUKEMIA

P. Bettencourt Medeiros[1,*], R. Bergantim[1], F. Trigo[1], J.E. Guimarães[1]
[1]Serviço de Hematologia Clínica, Centro Hospitalar de São João, EPE, Porto, Portugal

Background: Plasma cell leukemia (PCL) is a rare malignancy characterized by the proliferation of monoclonal plasma cells in the bone marrow and ≥2x10^{9}or ≥20% plasma cells in the peripheral blood. It is an aggressive disease, with a median survival of 7 to 11 months. Due to its rarity, it is difficult to design prospective studies or randomized trials in PCL, so collecting and publishing data from the largest number of cases is essential for the understanding of PCL's pathophysiology and outcome.
Aims: To characterize a series of PCL patients, in order to obtain data with the potential to be used as prognostic factors and to improve clinical outcomes.
Methods: Single-center, observational, retrospective study including all PCL cases admitted in our hospital between 2007 and 2016. Data regarding demography, clinical characteristics, laboratory results, treatment, *follow-up* and mortality were collected and analyzed using Statistical Package for Social Sciences (21stversion), searching for significant associations ($p<0.05$) with overall survival (OS) and progression free survival (PFS).
Results: 15 patients were included, with a median age of 58 years. Most patients were male (60%) and had PS ECOG 0-1 (93,3%) at presentation and primary PCL (80%). Median hemoglobin (Hb) and platelets values were 8,5 g/dl and 74x10^9/L, respectively. Median plasma cell percentage was 37.3% (peripheral blood) and 60% (bone marrow). IgG heavy chain was present in 33.3% and lambda light chains in 53.3% of cases. Most patients had total serum calcium ≥4.5mmol/L (60%), total proteins ≥65g/L (66.7%), monoclonal component ≤ 30g/L (53.3%), albumin ≥35g/L (60%), creatinine clearance ≥50ml/min (66.7%), elevated β-2 microglobulin (93.3%), ISS III (80%), R-ISS III (73.3%) and at least 1 cytogenetic change associated with poor prognosis in multiple myeloma (86.7%). Ten (66.7%) patients received bortezomib-based chemotherapy and nine patients (60%) were submitted, at least, to one autologous stem cell transplant (ASCT). Complete response (CR) or very good partial response (VGPR) were achieved, after chemotherapy, in 53.3% and, after ASCT, in 88.9% of patients. Mortality rate was 66,7%, with median PFS of 5 months and median OS of 4 months. In univariate analysis, OS was significantly associated with albumin ≤ 35g/L, splenomegaly and R-ISS III; PFS was significantly associated with platelets ≤100x10^9/L, splenomegaly and lambda light chains. In multivariate analysis, only the presence of splenomegaly kept its association with OS; none of the characteristics associated with PFS kept their significance. Chemotherapy followed by ASCT and the achievement of, at least, VGPR after chemotherapy and ASCT were associated with longer OS and PFS.
Summary/Conclusions: This study's retrospective design and the small sample limit the strength of our data and our conclusions. Interesting results were obtained regarding pre-treatment prognostic characteristics and the association of improved OS and PFS with treatment response and ASCT execution. More studies are necessary to determine the clinical relevance of this findings and the best treatment strategies in PCL.

PB1986

OPTIMIZATION OF POMALIDOMIDE PLUS LOW DOSE DEXAMETHASONE IN REFRACTORY/RELAPSED MYELOMA MULTIPLE PATIENTS

D. De Miguel[1,*], A. Gil[1], N. Golbano[1], M. Diaz[1], H. Guillen[1], A. Vazquez[1], B. Pinedo[1]
[1]Hematologia, Hospital universitario de Guadalajara, Guadalajara, Spain

Background: MM-003 study has presented a median PFS of 4.0 months and median OS was 13.1 months overall for Pomalidomide and low doses of dexamethasone in RRMM patients. Those results were better when a third drug was added (Poma-Dexa , Poma-Cyclophosphamide-dexa, and Poma-Bortezomib-dexa, ORR 38.9, 64.7 and 85%; PFS 4.4, 9.5, 10.7 months respectively).
Aims: To evaluate the response at therapy with pomalidomide plus dexamethasone in RRMM, and to analyze the efficacy of another drug in high risk MM.
Methods: we reported the clinical experience of the 8 patients treated with pomalidomide and dexamethasone. In patients with high risk MM (cytogenetic, extramedullary myeloma or plasmatic cell leukemia) pomalidomide and dexamethasone have had poor response. In those cases, we have added a third drug (cyclophosphamide or Bortezomib) and we have obtained the best results.
Results: we have used pomalidomide and dexamethasone in 4 patients and poma-dexa-cyclophosphamide in 3 patients (extramedullary myeloma) and

poma-bortezomid-dexa in 1 PCL patient. Table1. Demographic characteristic`s patients. Figure1. Response of monoclonal spike.

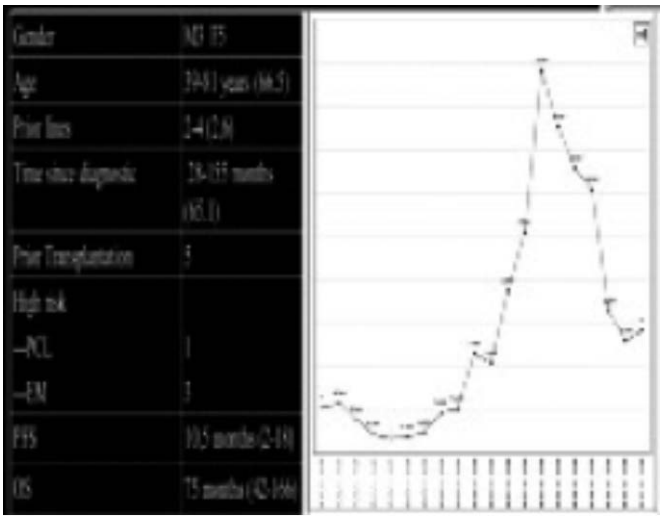

Figure 1.

Summary/Conclusions: pomalidomide, dexamethasone and a third drug (cyclophosphamide or Bortezomib) obtain best results (PFS and OS) in high risk RRMM patients. We have not reported more toxicity adding a third drug. In our experience, the response of the extramedullary myeloma with pomalidomide´s triplets is a great option.

PB1987

PROGNOSTIC SIGNIFICANCE OF PLASMABLASTIC PLASMA CELLS IN THE ERA OF NOVEL AGENTS IN MULTIPLE MYELOMA

A. Machet[1,*], S. Guidez[1], T. Systchenko[1], D. Desmier[1], N. Moya[1], C. Gruchet[1], V. Richez[1], A. Levy[1], F. Sabirou[1], A. Bobin[1], S. Bouyer[2], C. Tomowiak[1], P. Sonneveld[3], H. Avet-Loiseau[4], X. Leleu[1]
[1]Hematology, [2]Hematology Laboratory, University Hospital Center, Poitiers, France, [3]Hematology, University of Rotterdam, Rotterdam, Netherlands, [4]Laboratory for Genomic in Myeloma, Institut Universitaire du Cancer, Toulouse, France

Background: Plasmablastic (PB) feature of plasma cells in multiple myeloma (MM) has long been identified as poor prognosis. Interestingly it does not take part of International Revised Scoring System (R-ISS). Similarly, the prognostic impact in the era of novel agents and novel classes in MM is unknown. Finally, the percentage of PB in the bone marrow to which a poor prognosis develop is unclear.
Aims: To assess which modality of treatment of plasmablastic MM was associated with longer progression free survival (PFS) and overall survival (OS).
Methods: We have performed a retrospective analysis of all MM in our center from May 2005 to November 2016, and sought for MM with plasmablastic features, characterized by immature cells with high proliferative index rate. The PFS and OS were calculated since the first time the PB morphology was observed in the bone marrow aspiration, at the outset in newly diagnosed patients or in relapsed patients.
Results: 65 patients with PB were included. Adverse cytogenetic per IMWG criteria was reported in 6 patients, del17p x3, t(4;14) x3, and one with both. 33,8% were ISS 3, and 23,1% R-ISS 3. Extramedullary disease (EMD) was reported in 40%. 35 patients (53,8%) were in first-line therapy. The overall response rate with any triplet-based treatment containing always a proteasome inhibition and IMIds or alkylator was 49,2%, with 29,2% VGPR and 4,6% CR. The median PFS and OS were 6,9 and 14,9 months as a whole, respectively. The median PFS was greater when treatment combined bortezomib, lenalidomide and dexamethasone: 36,1 months ([0-99] *vs* 5,5 [0,59-10,4] otherwise; p=0,014). However, no difference in OS was demonstrated. Importantly, high dose therapy with ASCT was associated with longer PFS and OS, respectively 21,4 months ([12,8-30,1] *vs* 2,83 [0-5,7] p=0,003) and 50,4 months ([29,9-70,7] *vs* 6,27 [1,1-11,4] p=0,001). In multivariate analysis, poor OS was associated to acute renal failure at disease entry, presence of EMD, of del(17p), of hypercalcemia, and elevated lactate dehydrogenase. We then sought to demonstrate that use of a direct anti proliferative-based agent such as anthracycline would participate to rapid disease reduction and PB clone control. It turns out that there was no significant difference in terms of survival in patients treated with an anthracycline-based regimen.
Summary/Conclusions: this study confirms the poor prognosis of PB feature in MM. A triple-based association with a proteasome inhibitor (PI) and an immunomodulatory drug (IMiD) seems to provide the best PFS in MM with PB, ideally complemented by ASCT. The role of anthracycline remains to be demonstrated. This data will be validated in a large cohort.

PB1988

INTERNATIONAL OPPORTUNITIES TO COMPARE 'REAL WORLD' DATA FROM MYELOMA REGISTRIES: BASELINE CHARACTERISTICS, FIRST-LINE THERAPIES AND EARLY OUTCOMES FROM AUSTRIA AND AUSTRALIA/NEW ZEALAND

K. Bergin[1,*], R. Weger[2], E. Moore[3], Z. McQuilten[3], E. Wood[3], W. Willenbacher[4], A. Spencer[1]
[1]Haematology, Alfred Health-Monash University, Melbourne, Australia, [2]Oncotyrol Center for Personalized Cancer Medicine, Innsbruck, Austria, [3]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia, [4]Hematology & Oncology, Medical University Innsbruck, Innsbruck, Austria

Background: Most outcome data for multiple myeloma (MM) come from clinical trials which can not necessarily be extrapolated to 'real world' patients. More information is needed on patients treated in the 'real world' and in a wider range of settings.
Aims: To compare and contrast baseline characteristics, investigations, and initial therapies in different geographical regions, Australia/New Zealand (ANZ) and Austria, through first analysis of data from two established MM registries on behalf of the steering committees of the Australian and New Zealand Myeloma and Related Diseases Registry and the Austrian Myeloma Registry.
Methods: Analysis of data from newly diagnosed MM patients enrolled on the Austrian Myeloma Registry (AMR) and the ANZ Myeloma and Related Diseases Registry (MRDR) from 2012-2016.
Results: Available data from 250 and 691 patients from the AMR and ANZ MRDR, respectively, were included. DEMOGRAPHICS: The AMR cohort was younger (median age m:f 63.5 yrs:64 years *vs* 65 yrs:66 yrs on the AMR and MRDR, respectively). The proportion of male/female patients was similar between the AMR and MRDR (m:f 56%:44% and 61%:39% respectively). PRESENTATION: IgG myeloma was the most common sub-type of disease in both registries (m:f 64%:55% and 55%:58%, respectively) with more light chain only disease on the AMR (m:f 26%:33% *vs* 20%:19%). Presence of documented preceding plasma cell dyscrasias was similar (m:f 21%:19% *vs* 15%:20%, on the AMR and MRDR, respectively). INVESTIGATIONS: A higher proportion of patients underwent MRI (m:f 51%:58% *vs* 25%:27%) and skeletal survey (SS) (78% *vs* 60%) at diagnosis on the AMR than the MRDR, respectively. Baseline laboratory investigations were similar, however, patients on the MRDR demonstrated higher median LDH (m:f 176:178 *vs* 187:186 units/L) and serum calcium (m:f 2.34:2.28 *vs* 2.41:2.45 mmol/L) but decreased serum albumin (m:f 39:39g/L *vs* 35:35g/L) when compared to the AMR. STAGE: ISS staging was similar on both registries with ISS stage 2 being most common in both cohorts (m:f 42%:37% *vs* 40%:40%, on the AMR and MRDR, respectively) while ECOG performance status at diagnosis was lower in the MRDR cohort (ECOG≤1 m:f 43%:44% *vs* 81%:78%, on the AMR and MRDR, respectively). FIRST LINE THERAPY: First line therapy was predominantly bortezomib (Velcade - V) based on both registries (81% *vs* 85%). V/dexamethasone (D) was the most common on the AMR (29%) followed by V/thalidomide/D (VTD) (25%) with V/cyclophosphamide/D (VCD) (79%) most common on the MRDR. V was predominantly administered subcutaneously on both registries (79% *vs* 88%) but more commonly weekly on the MRDR (51% *vs* 67%) *versus* twice weekly on the AMR (40% *vs* 27%). RESPONSE TO THERAPY: Overall response rates were similar between the two cohorts but with higher CR rates on the AMR (CR 21% *vs* 11%, VGPR 27% *vs* 31%, PR 31% *vs* 43%, SD 12% *vs* 14% and PD 8% *vs* 2%, on the AMR and MRDR, respectively).
Summary/Conclusions: This pilot study between the AMR and ANZ MRDR demonstrates many similarities but also highlights significant differences, particularly in first line therapy and depth of response. Future studies between the AMR and MRDR will provide a platform for ongoing international benchmarking.

PB1989

DETECTING EARLY RELAPSE IN MULTIPLE MYELOMA AFTER ASCT: USEFULNESS OF IMMUNEASSAYS

M. Andrade-Campos[1,*], I. Murillo Flores[2], E. Colorado Ledesma[2], P. Giraldo[3]
[1]Translational Research Unit - Hematology, IIS-Aragon. CIBERER., [2]Hematology, Miguel Servet University Hospital, [3]Translational Research Unit, IIS-Aragon. CIBERER. IISCIII, Zaragoza, Spain

Background: The Free Light chain immunoassay (FLC) (Bindingsite, Birmingham, UK) is part of the mandatory response assessment for MM, the role of the Heavy/Light Chain immunoassay (HLC), is under investigation. Also relapses in MM patients are frequent, autologous stem cell transplantation (ASCT) is the standard consolidation therapy and there is an interest to detect early relapses and optimize therapy. We hypothesized that the combination of these techniques could permit to detect early biological (non-symptomatic) relapses (EBR) in this setting.
Aims: To analyze the usefulness of HLC and FLC to detect EBR in MM after ASCT.
Methods: A retrospective study was performed following these criteria: all patients diagnosed of secretory MM, in our center, and treated (including ASCT), between May 2011-August 2015; the protocol for follow-up included FLC, HLC, serum and urine electrophoresis (SPE, UPE) with immunofixation (IFX), pre-ASCT, after 12

weeks and every 3 months later (minimum follow-up: 6 months). EBR was defined as 25% on M-protein increase (any amount for patients on CR/SR) and/or ≥20mg/dl FLC increase, and/or 25% involved HLC increase with abnormal ratios. For urine, an increase >500mg/24 hrs of involved free-chain protein.
Results: Fifty-five patients were registered. Median follow-up 47 months. MF ratio: 29/26, mean age 59.5 y (33-71). Immunoglobulin subtype: IgG-Kappa: 41.8% (23), IgG-Lambda: 23.6% (13), IgA-Kappa: 16.4% (9), IgA-Lambda: 7.3% (4), Bence-Jones-Kappa: 3.6% (2), Bence-Jones-Lambda: 7.3% (4). Durie-Salmon Stage: IA: 13.5% (7), II-A: 32.7% (17), III-A: 44.2% (23), III-B: 9.6% (5), missing-data 3 case. All patients received Bortezomib based therapy and MEL200 as ASCT conditioning. Status pre-ASCT: minimal response: 12%, Partial Response (PR): 50.0%, very-good-PR (VGPR): 28.0%, complete response (CR): 6% and string response (SR): 4.0%. After ASCT, evaluation reveals that 13.0% achieved SR, 13.0% CR, 30.4% VGPR and 39.1% PR. During follow-up, 34/50 (68%) patients who achieved at least PR after ASCT, had a clinical relapse/progress, median PFS 41 months (31.5-50.5). EBR were detected in 28 patients, of them 22/34 (64.7%) clinically relapsed patients at median time 8.0 (2-22) months before symptomatic relapse. The EBR were detected by FLCr (36.7%), HLCr (22.7%), FLC+SPE (4.5%), FLC+IFX (9.1%), FLC+HLC+SPE (13.6%), FLC+HLC+SPE+UPE (13.6%).
Summary/Conclusions: Both FLC and HLC are useful tools to detect EBR in more than 50% of patients in our cohort ahead other techniques.

PB1990

EARLY MORTALITY (<6 M) IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS: COMPREHENSIVE INTERVENTION
V. Martínez-Robles[1,*], B. Ballina[1], S. Cerdá[1], N. de las Heras[1], M. Fuertes[1], L. Villalobos[1], J. A. Rodríguez-García[1], F. Ramos[1], F. Escalante[1]
[1]Hematología, Complejo Asistencial Universitario de León, LEON, Spain

Background: Early mortality in the first 6 to 12 months from diagnosis is well recognized in newly diagnosed multiple myeloma (NDMM) patients, with rates in the real-world setting of around 20-30%.
Aims: In a retrospective analysis of the causes of death performed by the end of 2012 we identify 2 different causes in the 2 consecutive periods analyzed. In the first period (1998-2006) the main cause was MM progression and in the second (2006-12) was secondary to serious infectious complications. Additional analysis were done after it an can identify a patient and a infectious profiles. Main risk factors from the patient were: age (over 75), suboptimal treatment and renal failure (calculated ClCr<50 ml/min). The infectious ocurred mainly in the first 3 months from diagnosis and principally polimicrobial and multiresistent infections.
Methods: After this analysis several measures were taken to reduce this high early mortality: 1) To promote the ambulatory regime both in diagnosis and for the rapid assessment of complications to avoid or shorten income and to reduce these nosocomial-behaviour infection complications. 2) Early initiation of "optimal" anti-myeloma treatment. 3) Get infectious prophylaxis in patients over 75 years and / or renal failure with Septrim ©.
Results: 343 pac NDMM were treated between 1998 and 2015 (127 in the 1st period, 115 in the 2nd: 242 pts before 2013; and 101 in the 3rd period: 2013-15). The median age at dx was 74 years (39-100). The number of patients died <6m was 77 years. 60 died before 6 months: 55 before 2013 (29 in the 1st period (22.8%) and 26 in the 2nd (22.6) and 5 after 2013 (5.0%). Of these 60, 37 had a severe infectious complication. The main cause of mortality before 2013 was infectious complications, (14 of 28 early death in the first period and 22 of 26 in the second). Severe pneumococcal infections were infrequent (11%) In the 3rd period, mortality <6m was reduced by 77% (22% *vs* 5%) (p.001); There was only 1 severe infection (G5) in this period (CMV reactivation, probably Pneumocystis pulmonary infection, E. Coli bacteriemia and a intestinal necrosis after an atrial fibrilation embolism) Figure 1 (upper corner). Improvement in early mortality increases significatly overall survival: 32.5 monts vs not reached pre and post-2013 (p.0034).

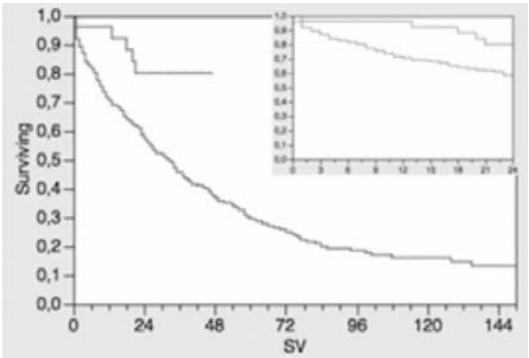

Figure 1 (large graphic; legends: red: pre2013; blue: post2013).

Summary/Conclusions: Infectious complications and progression of MM have been the main cause of early mortality in patients with NDMM. Identifying potential "modifiable" variables and acting on them improves the short-term prognosis of patients with NDMM like: Supportive treatment to prevent infectious complications (avoid unnecesary hospitalization, antibiotical prophylaxis) and rapid access to optimal antiMM treatments. These improvemente of short-term

PB1991

FIRST LINE USE OF NOVEL AGENTS BEFORE AUTOLOGOUS SCT HAS A POSITIVE IMPACT ON TIME TO SECOND PROGRESSION AND SURVIVAL IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA UNDER 70 YEARS
S. Gassiot[1,2,*], C. Motlló[1,3], M. Morgades[1], Y. Gonzalez[4], M. Garcia-caro[1], J.-M. Ribera[1,2], A. Oriol[1,2]
[1]Hematology, Hospital Germans Trias i Pujol - ICO, Badalona, [2]Universitat Autònoma de Barcelona, Cerdanyola del Vallès, [3]Universitat Autònoma de Barcelona, Badalona, [4]Hematology, Hospital Dr Josep Trueta, Girona, Spain

Background: Most clinical trials for multiple myeloma (MM) patients using novel agent-based regimens before autologous stem cell transplantation have shown improvement in response rates and progression-free survival, however they have failed to identify a significant overall survival (OS) benefit.
Aims: Our aim is to analyze the potential impact of initial induction in the feasibility and outcome of subsequent treatment lines and other major factors affecting OS in a real clinical practice setting.
Methods: Newly MM patients less than 70 years of age diagnosed between December 1999 and December 2009 were prospectively registered. Patients were assigned to a first cohort if they received conventional chemotherapy (CC) induction regimens with new agents available at relapse or to a second cohort if received novel agents based first line treatment (NA).
Results: The overall response rate after completing first line treatment for all the 154 eligible patients was 85%, 79% in CC compared to 94% in NA (*P*=0.012). Very good partial response or better for NA was significantly higher than for CC (39% *vs* 59%, *P*=0.012). Patients in NA demonstrated not only a superior median progression-free survival (2.8 years *vs* 1.6 years, *P*=0.03) but also superior median progression-free survival from diagnosis to second progression – PFS2 (5.2 years *vs* 2.7 years, *P*=0.003). In both cohorts PFS1 and PFS2 represented more than 50% and 80% of life expectancy respectively. It could be hypothesized that CC patients would obtain more benefit than NA patients of second-line therapy, as they would be naïve to the novel agents used at relapse, but this is not the case. The use of thalidomide and/or bortezomib induction did not reduce the efficacy of these same agents second line. Indeed, these patients also had the best second responses that also contributed to longer PFS2 periods. After a median follow-up of 6.97 years, clear differences in OS were observed (7.97 years for NA compared to 3.35 years in CC, *P*<001). Despite the fact that better risk patients in the NA group were more likely to remain in first or second response, relapsed and refractory patients in this group still presented longer survivals beyond second relapse than patients in the CC group (Figure 1).

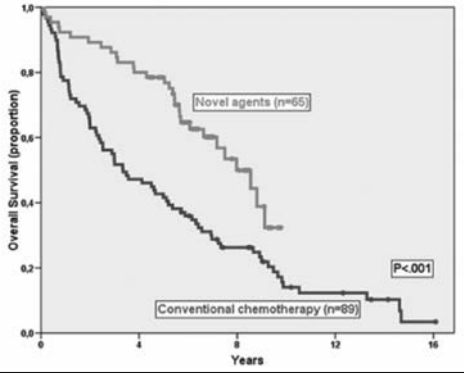

Figure 1.

Summary/Conclusions: New agent based first line induction treatments in newly diagnosed MM patients provide benefits beyond first progression free survival that contribute to a significant improvement in OS.

PB1992

SAFETY AND EFFICACY OF NOVEL AGENTS IN VERY ELDERLY MULTIPLE MYELOMA PATIENTS (AGED 80 YEARS OR MORE): A REPORT BY THE RETE EMATOLOGICA PUGLIESE (REP)
N. Sgherza[1,*], A. P. Falcone[1], A. Iacobazzi[2], G. Palumbo[3], B. Rossini[4], G. Mele[5], P. Curci[6], L. Ciuffreda[7], G. Polimeno[8], G. Rossi[1], G. Tarantini[7], G. Specchia[6], A. Melpignano[5], V. Pavone[4], S. F. Capalbo[3], A. Guarini[2], N. Cascavilla[1]

[1]Hematology Unit, IRCCS, Casa Sollievo della Sofferenza, San Giovanni Rotondo, [2]Hematology Unit, IRCCS, Istituto Tumori "Giovanni Paolo II", Bari, [3]Hematology Unit, Azienda Ospedaliero-Universitaria Ospedali Riuniti, Foggia, [4]Hematology Unit, Ospedale "Card.G.Panico", Tricase, [5]Hematology Unit, Ospedale Perrino, Brindisi, [6]Hematology Unit, Azienda Ospedaliero-Universitaria Policlinico di Bari, Bari, [7]Hematology Unit, Ospedale Di Miccoli, Barletta, [8]Hematology Unit, Ospedale "Miulli" , Acquaviva delle Fonti, Italy

Background: Multiple Myeloma (MM) is mainly a disease of the elderly and the very elderly patients (80 years of age or more) comprise one third about of all MM patients. This subset of patients suffer from concomitant disabilities and/or comorbidities and require a different and a more individualized therapeutic approach, including the novel agents.
Aims: The aim of our study is to verify safety and efficacy of novel agents with the reliability to maintain a good quality of life and obtain a maximal disease control.
Methods: Patients from 8 Hematology Centers of the "Rete Ematologica Pugliese (REP)" were included in this study. Between January 2011 and December 2016, 71 patients (M/F: 42/29) with a median age of 82 years (range 80-91) were diagnosed as newly symptomatic MM. Of the entire study population, 40 (56%) patients showed an ECOG score lower than 2. According to immunoglobulin heavy and light chain isotypes, patients had IgG-k (n=23), IgG-λ (n=16), IgA-k (n=14), IgA-λ (n=6), micromolecular k (n=8) and λ (n=4) chains. On the basis of ISS, patients were classified as I (n=4) score, II (n=23) and III (n=44) score, respectively. When CRAB features were considered, bone lesions represented the most frequent (n=43, 60.6%) clinical manifestations, while anemia, hypercalcemia and renal failure were found in 35 (49.3%), 2 (2.8%) and 2 (2.8%) patients, respectively. Majority of patients (n=49, 69%) showed at least 1 comorbidity requiring specific treatments, and 11 patients (15,5%) showed more than 3 comorbidities. Patients were treated according to Bortezomib-based regimens (VMP, VCD and VD) (n=45; 63.4%), Lenalidomide-based regimen (RD) (n=8; 11,3%) and Thalidomide-based regimen (MPT) (n=5; 7%). Only 13 patients (18.3%) did not receive any novel agent.
Results: Based on IMWG criteria, 15 patients (21.1%) achieved a CR, 15 patients (21.1%) a VGPR and 15 patients (21.1%) a PR. Fourteen patients (19.7%) and 12 (17%) patients experienced a SD and a PD, respectively. As second line of treatment, Bortezomib was used in 14 (33.3%) patients, Lenalidomide in 17 (40.5%) patients and Thalidomide in 3 (7,2%) patients. Height patients (19%) were treated with old drugs (Melphalan, Cyclophosphamide or Bendamustine). Pomalidomide was used as third line-therapy in 3 patients. After 72 months (median 32.5 months) of follow-up, 33 (46.5%) patients remained alive with a median survival of 36 months and 25 (28.2%) died. Last follow-up from 13 patients was unavailable. Hematological and extra-hematological toxicities were similarly distributed (18,3% and 18,3%, respectively) and usually weak/moderate. Neuropathy was the most common toxicity reported (n=5, 7%). Of patients treated with only novel agents (n=58), hematological and extra-hematological toxicity was observed in 14% and 16% patients, respectively.
Summary/Conclusions: We showed that all MM patients can be treated by novel agents independently of the age. Results from our study show that particularly very elderly and frail patients can benefit from these drugs by prolonging their life expectancy and maintaining a good quality of life.

PB1993

BORTEZOMIB-MELPHALAN-PREDNISONE *VERSUS* MP AS INITIAL TREATMENT FOR VERY ELDERLY PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

M.K. Kim[1,*], K. Kim[2], D.H. Yoon[3], C. Suh[3], J.H. Moon[4], Y.J. Lee[4], J.H. Lee[5], S.-H. Jung[6], H.J. Kim[7], S.H. Bae[8], J.S. Kim[9], J.-O. Lee[10], H.S. Eom[11], W.-S. Lee[12], H.J. Kang[13], Y.-C. Mun[14], Y.R. Do[15], M.S. Hyun[16]
[1]internal medicine, Yeungnam University College of Medicine, Daegu, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, [3]University of Ulsan College of Medicine, Seoul, [4]Kyungpook National University Hospital, Daegu, [5]Gachon University Gil Hospital, Incheon, [6]Chonnam National University Hwasun Hospital, Hwasun, [7]Hallym University Sacred Heart Hospital, Anyang, [8]Catholic University College of Medicine of Daegu, Daegu, [9]Severance Hospital, Yonsei University College of Medicine, Seoul, [10]Seoul National University Bundang Hospital, Seongnam, [11]National Cancer Center of Korea, Goyang, [12]Busan Paik Hospital, Busan, [13]Korea Cancer Center Hospital, [14]Ewha Woman's University School of Medicine, Seoul, [15]Keimyung University School of Medicine, Daegu, [16]Yeungnam University Hospital, Deagu, Korea, Republic Of

Background: Although bortezomib-melphalan-prednisone (VMP) therapy is a well-established standard treatment for patients with multiple myeloma (MM) who are ineligible for high-dose therapy, it is not clear whether very elderly patients should be treated with VMP in clinical practice, considering the toxicities.
Aims: The purpose of this case-control study was to compare the efficacy of VMP *versus* melphalan-prednisone or cyclophosphamide-prednisone (MP/CP) as initial therapy for very elderly patients.
Methods: We retrospectively studied 233 patients aged 75 years or older with newly diagnosed multiple myeloma between March 2007 and February 2015. One-hundred thirty one patients received VMP and 102 patients received MP/CP regimen were enrolled from 15 institutions throughout Korea.
Results: Patient characteristics were comparable in these two groups. Overall response rate was 70.2% in VMP patients and 48.0% in MP/CP patients (P=0.001). Complete response rate was 22.9% in VMP patients and 7.8% in MP/CP patients (P=0.002). After a median follow-up for survivors of 28.5 months, progression-free survival (PFS) and overall survival (OS) were significantly different between the two groups (PFS, median 21.3 *vs* 11.8 months in VMP and MP/CP group, respectively, P=0.018; OS, median 34.9 *vs* 22.8 months in VMP and MP/CP group, respectively, P=0.006). Nonetheless, for 61 patients who were aged ≥80 years, PFS and OS was not significantly different between the two groups (PFS, median 19.6 *vs* 13.2 months in VMP and MP/CP group, respectively, P=0.378; OS, median 27.8 *vs.*17.8 months in VMP and MP/CP group, respectively, P=0.443).
Summary/Conclusions: Although VMP therapy was associated with a significant improvement in overall survival among patients ≥75 years, there is no differences for patients aged 80 or older. Frailty and comprehensive geriatric assessment should be incorporated to guide treatment decisions for this population.

PB1994

EFFICACY OF AUTOLOGOUS STEM CELL TRANSPLANTATION FOR THE TREATMENT OF MULTIPLE MYELOMA IN HIV-POSITIVE PATIENTS – A CASE-SERIES

B. Ni[1,*], A. Rosko[2], D. Benson[2], S. Devine[2], C. Hofmeister[2], Y. Efebera[2]
[1]Department of Internal Medicine, [2]Division of Hematology, Department of Internal Medicine, The Ohio State University, Columbus, United States

Background: While hematopoietic malignancies are found at increased rates in individuals with acquired immunodeficiency syndrome (AIDS), coincidence of multiple myeloma (MM) and human immunodeficiency virus (HIV) is less common, leading to a paucity of expertise in the treatment of individuals with these co-morbid conditions. Prior to the advent of highly active anti-retroviral therapy (HAART), autologous stem cell transplant (ASCT) was relatively contraindicated for MM patients with HIV due to issues associated with stem cell harvest and the risk of opportunistic infections. With the widespread use of HAART for control of HIV, high dose chemotherapy and ASCT is now the preferred treatment for relapsed lymphoma, the leading hematopoietic malignancy associated with HIV/AIDS. It stands to reason that MM patients with HIV on HAART may benefit equally from aggressive combination treatment of chemotherapy and ASCT.
Aims: This study seeks to evaluate the clinical course and treatment outcomes of patients with HIV and MM treated with high dose therapy and ASCT.
Methods: A single center retrospective case-series study was performed. Data from patients who were HIV-positive and on HAART undergoing ASCT for treatment of MM between January 2000 and June 2016 were collected and analyzed.
Results: The following Table 1 lists patient characteristics. All were male with average age 53.2 years. All were diagnosed with HIV prior to diagnosis of MM and were appropriately treated with HAART prior to ASCT. All patients had undetectable HIV viral titer prior to ASCT, and most remained undetectable after ASCT. Four of five patients had CD4 >200/uL and one patient had CD4 <50/uL prior to ASCT; however all patients recovered CD4 counts after ASCT (and most with improved CD4 count). Adequate CD34(+) stem cells were collected. Patients received high dose melphalan (200 mg/m^2) followed by ASCT. HAART was continued during ASCT. Patients experienced usual ASCT toxicities including diarrhea, mucositis, and neutropenic fever. One patient developed sepsis and small bowel obstruction, which resolved with antibiotics and conservative management. All patients had normal neutrophil and platelet engraftments. Post ASCT responses were complete remission (2 patients), very good partial remission (1), partial remission (1) and minimal response (1). All patients are currently alive without relapse or progression 1-4 years from ASCT and receiving post ASCT maintenance with lenalidomide.

Table 1.

Case	Patient #1	Patient #2	Patient #3	Patient #4	Patient #5
Sex	Male	Male	Male	Male	Male
Race	Caucasian	Caucasian	Caucasian	Caucasian	African-American
Age at ASCT	58	48	52	58	50
ISS Stage	Stage I	Stage I	Stage II	Stage III	Stage I
Marrow cellularity	30%	40%	70%	65%	not determined
Cytogenetics	del(13q)	+11q	46XY	46XY	abnormal
CD34 cells collected (10^6 cells/kg)	11.95	21.34	10.81	10.91	9.47
Date ASCT	7/18/2013	7/20/2013	12/10/2015	5/18/2016	7/20/2016
Length of hospital stay (days)	16	17	27	18	13
Days to neutrophil engraftment	11	12	13	10	9
Days to platelet engraftment	11	13	16	11	10
Disease Status	CR	CR	PR	VGPR	MR
Overall Survival (days)	1295	1314	375	279	173
HIV viral load before ASCT (copies/mL)	undetectable	undetectable	undetectable	undetectable	undetectable
CD4 before ASCT (cells/μL)	248	44	370	564	321
HIV viral load after ASCT (copies/mL)	undetectable	76073	undetectable	undetectable	undetectable
CD4 after ASCT (cells/μL)	314	198	1028	221	278

Summary/Conclusions: Multiple myeloma patients with concurrent HIV infection that is controlled on HAART tolerate ASCT for treatment of myeloma as well as myeloma patients without HIV infection and have generally good outcomes.

PB1995

FEASIBILITY OF USING GLOBAL FDG UPTAKE IN BONE MARROW TO ASSESS TREATMENT RESPONSE IN MULTIPLE MYELOMA

B. Oestergaard[1,*], W.Y. Raynor[2], M.Z. Zirakchian[2], R. Taghvaei[2], A. Nielsen[3], J.T. Asmussen[4], P. Holdgaard[5], T. Plesner[6], A. Alavi[2], N. Abildgaard[1], P.F. Høilund-Carlsen[3]
[1]Hematology, Odense University Hospital, Odense, Denmark, [2]Radiology, Hospital of the University of Pennsylvania, Philadelphia, United States, [3]Nuclear Medicine, [4]Radiology, Odense University Hospital, Odense, [5]Nuclear Medicine, [6]Hematology, Vejle Hospital, Vejle, Denmark

Background: Multiple myeloma (MM) is characterized by plasma cell proliferation and expansion primarily in the bone marrow. Modern assessment of MM using FDG-PET has so far mostly been limited to the analysis of focal lesions, requiring subjective interpretation to determine overall disease activity.
Aims: A novel method using CT segmentation to determine global bone marrow activity portrayed by FDG uptake was used to achieve a comprehensive understanding of disease burden in patients with MM before and after therapy.
Methods: Prospective FDG-PET/CT data of 23 MM patients between ages of 50 and 76 (mean=64.3, males=21, females=2) were collected from Odense University Hospital (NCT02187731) and included scans before initiation of treatment and at end of treatment (EOT) two months after high dose chemotherapy with stem cell support. . All scans were conducted 60 min after intravenous injection of 4 MBq/kg of FDG. Images were analyzed using an iterative thresholding algorithm that delineates a continuous region based on Hounsfield units from the CT data (OsiriX software; Pixmeo SARL; Bernex, Switzerland), allowing for segmentation of the total skeleton on a fused PET/CT image. This enabled the quantification of FDG uptake representing the entire skeleton, providing a global SUVmean that considers all bone marrow involvement. Global SUVmean scores were compared before and at EOT using a two-tailed paired t test.
Results: A decrease in marrow FDG uptake was observed at EOT compared to baseline in most patients. The calculated global SUVmean uptake decreased after initiation of treatment in 17 (73.9%) of the cases and increased in 6 (26.1%) of the cases, supported by the observed statistical difference of the dependent means before and after treatment (P=0.0053).
Summary/Conclusions: We assessed the effects of treatment in MM patients using a novel technique for global quantification of FDG uptake in the bone marrow and skeleton and found lower global uptake at EOT. However, a limitation of bone segmentation is present in cases with extramedullary disease. Global assessment rather than focal analysis of discrete lesions represents a robust and straightforward method of determining total disease activity that potentially will be of value in treatment evaluation, disease monitoring and prognostication in multiple myeloma.

PB1996

VALUE OF MYELOMA PROGNOSTIC INDICES IN ERA OF NOVEL DRUGS IN TRANSPLANT SETTING

V. Zatezalo[1,*], A. Hanžek[1], N. Gredelj-Šimec[1], V. Milunović[1], M. Bogeljić-Patekar[1], M. Lukić[1], B. Jelić-Puškarić[2], A. Škrtić[3], D. Radić-Krišto[1,4], S. Ostojić Kolonić[1,5]
[1]Department of Hematology, [2]Department of Cytology, [3]Department of Pathology, Clinical Hospital Merkur, Zagreb, [4]School of Medicine, Osijek, [5]School of Medicine, Zagreb, Croatia

Background: Despite the era of emerging novel agents, autologous peripheral blood stem cell transplantation remains backbone of myeloma treatment.
Aims: The main aim of our study was to evaluate the role of tandem transplantation in myeloma treatment as well as prognostic indices in era of novel drugs.
Methods: We consecutively included all patients transplanted due to myeloma at our center from 2012 to the end of 2016. Patients were treated with either VAD or bortezomib based therapy. After induction treatment, all patients proceeded to mobilization therapy cyclophosphamide 3g/m^2 and received pegfilgrastim. Preparative regimen was either MEL 200 for fit patients or MEL 140 for frail and those with severe renal function impairment. Patients treated with VAD who had poor response after autologous transplantation were subsequently treated with bortezomib based therapy. We examined following baseline characteristics: age, proportion of plasma cells in bone marrow biopsy or aspirate, FISH and lactate dehydrogenase (LDH). Additionally, for each patient International Staging System (ISS), Revised International Staging System (ISS-R) and Durie Salmon staging were calculated. Patients with other malignant diseases prior to myeloma diagnosis were excluded. The main outcomes were overall survival (OS) defined as death from myeloma or any other cause and time to next treatment (TNT), defined as time from transplant to next new therapy or death of any cause.
Results: From January 2012 to December 2016 hundred and one patient with MM (49 male, 52 female), median age 55 (range 22-71), were transplanted. Bortezomib based induction therapy was used in 55 (54,5%) and VAD induction was used in 46 (45.5%) patients. Median OS of all treated patients was 73 months; median OS of VAD group was 73 months while in bortezomib group median OS was not reached, but this difference was not statistically significant (p=0,13). TNT was significantly longer in bortezomib group than in VAD one (27,8 *vs* 17,5 months respectively; p=0,02). Interestingly prognostic indices could not discriminate patient groups according to OS (p=0,1), but could discriminate them due to TNT (p=0,008), possibly due to cross-over to bortezomib treatment after treatment failure. TNT had a significant correlation with levels of LDH (p=0,04) and no significant correlation with number of plasma cells in bone marrow. OS was significantly longer in those with longer duration of time to next treatment (p=0,0004). There was no difference in OS or TNT in patients treated with tandem transplant *vs* single transplant (p=0,68 and p=0,57 respectively), possibly due to heterogeneity of tandem group.
Summary/Conclusions: Even though novel drug therapy seems to converge risk groups to lower ones, prognostic indices remain relevant. Due to heterogeneity of patients and myriad of known prognostic factors further studies are needed so they may be translated into risk adapted therapy approach.

PB1997

WHICH ORGAN SHOULD WE BIOPSY TO DIAGNOSE AL AMYLOIDOSIS?

L. Llorente Gonzalez[1,*], C. de Miguel Jiménez[1], C. Salas[2], P. García-Pavía[3], E. Gonzalez[3], J. A. López del Olmo[4], J. M. Vazquez Cobos[4], I. Krsnik[1]
[1]Hematology, [2]Anatomical Pathology, [3]Cardiology, Hospital Universitario Puerta de Hierro de Majadahonda, [4]Cardiovascular Proteomics, Centro Nacional de Investigaciones Cardiovasculares Carlos III, Majadahonda, Spain

Background: Light chain (AL) amyloidosis is a deposition disease with can affect many organs and with a variable but usually bad, prognosis. Therapy requires a quick and correct diagnosis. Accurate identification of amyloid deposition and of the amyloid subtype in tissue biopsies is thus, mandatory. Random biopsies of easily accessible tissues such as subcutaneous fat, gingivae or rectum are usually recommended but sensitivity of this approach is low.
Aims: To present our experience with tissue biopsies performed in 62 consecutive patients diagnosed of AL amyloidosis in our center.
Methods: We reviewed all tissue biopsies performed during the study period (2004-2017) in 62 consecutive patients diagnosed of AL amyloidosis at the same center. A bone marrow (BM) biopsy was performed per protocol in all cases. Decisions on biopsies were taken considering organ involvement and accessibility: skin, lymph nodes, lung or tongue biopsies were performed when lesions were seen on clinical or X-ray examinations, cardiac biopsies in the presence of increased NT-proBNP (N-terminal natriuretic peptide) levels and typical echocardiographic findings, kidney biopsies in patients with nephrotic syndromes. Biopsies were stained with Congo Red and read under polarized light with a Texas filter. Subtyping of the amyloid was done using anti-kappa, anti-lambda, anti-TTR and anti-A antisera. If any biopsy was positive for AL amyloid, no further biopsies were performed unless necessary for therapeutic decisions.
Results: A total of 152 biopsies were performed during the study period: see Table 1.

Table 1.

Tissue	Biopsies	AL amyloidosis
Bone marrow	59	25 (42.2%)
Heart	37	33 (89.2%)
Kidney	8	8 (100%)
Intestine/Rectum/ Stomach	10	7 (70%)
Gingivae	13	4 (30.7%)
Subcutaneous fat	11	4 (36.4%)
Liver	2	2 (100%)
Skin	2	2 (100%)
Tongue	3	3 (100%)
Lung	2	2 (100%)
Sural nerve	3	3 (100%)
Lymphnode	1	1 (100%)
Tonsil	1	1 (100%)
Total of biopsies	152	95 (94.7%)

Summary/Conclusions: Prognosis in AL amyloidosis is slowly improving with the use of new anti-myeloma drugs and may improve further with new monoclonal antibodies. Therapy requires an early and accurate diagnosis. We do not perform random biopsies of tissues such as fat or gingivae due to low sensitivity. In our hands biopsies of tissues or organs with clinical, analytical or radiological involvement shows higher sensitivity. A bone marrow biopsy is required for diagnosis of the neoplastic disease underlying AL amyloidosis and may show amyloid in up to 50% of the cases. Cardiac biopsy is also highly sensitive and in centers with a high degree of expertise such as ours, has no complications. Our data allow us to recommend a different approach to AL amyloidosis of what is usually published. Biopsies of clinically involved organs yields almost 100% sensitivity. Random biopsies of gingivae, subcutaneous fat or rectum should be discouraged.

PB1998

A COMPARISON OF CYCLOPHOSPHAMIDE-GLUCOCORTICOIDS AND LENALIDOMIDE-DEXAMETHASONE AS TREATMENT FOR MULTIPLE MYELOMA IN FIRST RELAPSE AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION

R. Sterrett[1,*], A. Figueiredo[2], R. Mallick[3,4], N. Kekre[1,2,5], H. Atkins[1,2,5], A. McCurdy[1,2,5]
[1]Department of Medicine, University of Ottawa, [2]Ottawa Hospital Research Institute, [3]School of Epidemiology, Public Health and Preventive Medicine, University of Ottawa, [4]Clinical Epidemiology Program, Ottawa Hospital Research Institute, [5]Division of Hematology, The Ottawa Hospital, Ottawa, Canada

Background: The optimal management of relapsed Multiple Myeloma (MM) with respect to therapeutic combinations and sequence remains controversial and is actively evolving. Many commonly used regimens have not been directly compared. These agents vary widely in cost, and knowledge of their relative efficacy is of particular importance in regions where cancer medicines are publicly funded.
Aims: We sought to compare the efficacy and safety of two commonly used regimens for relapsed MM using historical cohorts from a single transplant center.
Methods: A retrospective observational study was performed between January 1991 and November 2016 to compare the efficacy of cyclophosphamide and dexamethasone/prednisone (Cyclo), or lenalidomide and dexamethasone (Len-Dex) for relapsed MM post autologous stem cell transplant (auto SCT). The primary outcome was Time to Next Treatment 2 (TTNT2), defined as time from first relapse requiring therapy after auto SCT to second relapse requiring therapy. The secondary outcome was overall survival, defined as time of diagnosis to death from any cause. Outcomes were assessed by Kaplan Meier methods and overall differences determined by log rank test. Hazard ratios were calculated for individual treatment groups and compared by univariate and multivariate logistic regression.
Results: A total of 243 patients underwent treatment for MM at first relapse post autologous transplant. Of these, 139 were included in this analysis: 88 Cyclo and 51 Len-Dex. Patient demographics and disease characteristics were similar between each group for age, sex, subtype of MM and ISS Stage (p>0.05). Vincristine, Doxorubicin and Dexamethasone (VAD) was the most common treatment at diagnosis for the Cyclo group (68%), whereas bortezomib-based therapy was the most common for the Len-dex group (76%) (p<0.0001). No differences were observed in overall response rate or depth of response based on induction therapy between both groups. Median time to first relapse requiring treatment after auto SCT was longer in the Cyclo group, 36 months *vs* 25 months (p=0.0008). The median TTNT2 was similar for the two groups: 12.2 months (IQR, 4.56-27.96) for Cyclo and 12.1 months (IQR, 4.80-29.16) for Len-dex (p=0.52). However, after adjusting for standard patient and disease related factors in a multivariate model, TTNT2 was shorter for Cyclo compared to Len-dex (HR 2.29; 95% CI, 1.17 – 4.51; p=0.016). The median overall survival was 84 months for Cyclo and 75.6 months for Len-dex (p=0.31). In the multivariate analysis, overall survival was not different for Cyclo compared to Len-dex (HR 0.99; CI 0.42 – 2.34; p=0.99). There was no significant difference in rates of hospitalization, infection, or grade 3 adverse events between the two groups (Figure 1).

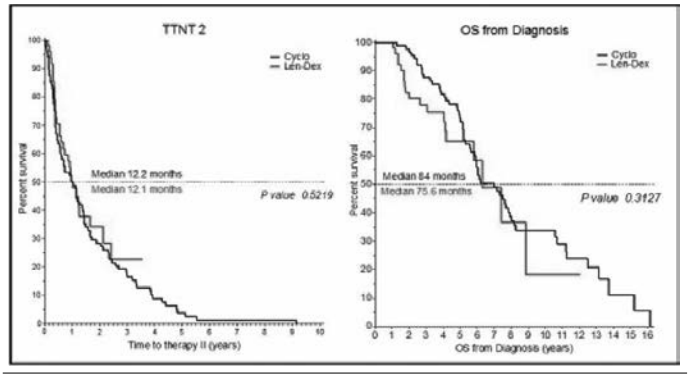

Figure 1. Survival curves.

Summary/Conclusions: In this observational study of patients with relapsed multiple myeloma post autologous stem cell transplantation, Lenalidomide-dexamethasone was associated with longer TTNT2 compared with Cylophosphamide-glucocorticoids. However, there was no difference in overall survival. Cyclophosphamide is considerably less expensive than the novel agents. In an era when fiscally sustainable care for MM remains a challenge, further prospective studies are required to compare cyclophosphamide with novel agents in the management of relapsed multiple myeloma.

PB1999

CLINICAL IMPACT OF THE PLASMA LENALIDOMIDE CONCENTRATION AND THE ANALYSIS OF ANTI-TUMOR IMMUNE RESPONSE IN NEWLY DIAGNOSED MULTIPLE MYELOMA TREATED WITH LENALIDOMIDE AND DEXAMETHASONE THERAPY

T. Kobayashi[1,*], M. Miura[2], T. Niioka[2], Y. Fujioka[1,3], M. Abumiya[2], S. Ikeda[1], T. Yoshioka[1], Y. Kameoka[1], H. Nishikawa[3], N. Takahashi[1]
[1]Hematology, Nephrology and Rheumatology, Akita University Graduate School of Medicine, [2]Pharmacy, Akita University Hospital, Akita, [3]Division of Cancer Immunology, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center, Chiba, Japan

Background: Lenalidomide (Len) and dexamethasone (DEX) combination therapy (Ld) is now the standard treatment of multiple myeloma (MM). Len has both a direct effect on MM cells and an immunomodulatory effect and recently many drugs are combined with Ld therapy to expect the synergistic anti-tumor immune response. However, adverse events (AEs) make continuation of Ld therapy difficult for some patients especially for elderly patients.
Aims: To investigate the safe and effective plasma concentration of Len and the anti-tumor immune response change in MM patients treated by Ld therapy.
Methods: Forty patients (18 men and 22 women) were enrolled in this study. Median age was 75.5 years old (range 61-86). Len was administered on days 1–21 of a 28-day cycle; and DEX, on days 1, 8, 15, and 22. The plasma concentrations of Len just before oral administration and 1, 2, and 4 hr thereafter were analyzed by using liquid chromatography-tandem mass spectrometry. Before and after Ld therapy, Peripheral blood mononuclear cells (PBMCs) of MM patients were isolated from whole blood by Ficoll-Hypaque density-gradient centrifugation. PBMCs were stained with the fluorescent dye-conjugated antibodies against surface and intracellular antigens and evaluated by multicolor flow cytometry. Intracellular cytokine production of IFN-γ, TNF-α, IL-2 and CD107a molecule was detected after stimulation with PMA/ionomycin for 5 hours in the presence of protein transport inhibitor Golgi stop (BD Bioscience). Analysis was performed using LSR Fortessa (BD Bioscience) and Flowjo version 10.2 software (TreeStar). This study protocol was approved by the Ethics Committee of Akita University Hospital, and all recipients gave written informed consent.
Results: 21 patients showed renal impairment (RI) necessary to adjust initial Len dosage. Adverse cytogenetics of del17p and t(4;14), detected by using fluorescence *in situ* hybridization, were found in 2 and 4 patients, respectively. The median initial dosage of Len was 15 mg and DEX 20 mg. The overall response rates were 68.6% and the 2-year progression-free survival was 70.8% at a median follow-up of 26.5 month. Grade 3 to 4 nonhematologic AEs were observed only in 8 patients. We estimated the $AUC_{0\text{-}24}$ of Len by using formula as we previously reported (Ther Drug Monit 2014) and the cut-off value of the hematologic AEs was 2613.5ng•hr/ml (sensitivity 81.8%, specificity 80%) and non-hematologic AEs 3023.6ng•hr/ml (sensitivity 78.9%, specificity 62.5%). After Ld therapy, naïve subset of CD4 and CD8 T cells and monocytic MDSC reduced significantly. On the other hand, effector memory subset and intracellular cytokine productions of IFN-γ, TNF-α, IL-2, and CD107a of CD4 and CD8 T cells increased significantly (Figure 1).

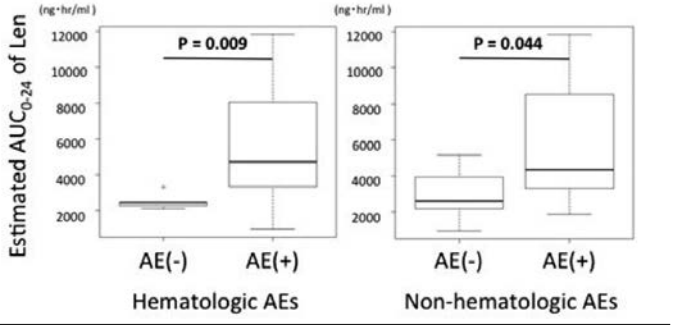

Figure 1.

Summary/Conclusions: Len can be administered safely even in elderly patients with RI by using the estimated $AUC_{0\text{-}24}$ of Len as a prediction marker of AEs. Enhanced cytokine production and increased memory subset of T cells were observed after Ld treatment.

PB2000

THE ROLE OF EXPRESSION CD56 ON BONE MARROW PLASMA CELLS AND EXTRAMEDULLARY PLASMA CELLS IN PATIENTS WITH MULTIPLE MYELOMA

M. Firsova[1,*], L. Mendeleeva[1], A. Kovrigina[2], M. Soloviev[1], O. Pokrovskaya[1], M. Nareyko[1], L. Kuzmina[3], V. Savchenko[4]
[1]Department of High-Dose Chemotherapy of Paraproteinemic Hemoblastosis, [2]Pathology department, [3]Bone Marrow Transplantation Department, [4]National Research Center for Hematology, Moscow, Russian Federation

Background: The myeloma cells interact with the bone marrow microenvironment by several adhesion molecules. One of them is CD56 (a neural cell-adhesion molecule N-CAM) – a membrane glycoprotein, a member of the immunoglobulin superfamily, expressed on the surface of malignant plasma cells of patients with multiple myeloma (MM). Decreased expression of CD56 is considered as one of the possible factors, that help tumor cells to spread outside the bone marrow.
Aims: To evaluate the impact of CD56 expression on the rate of overall survival (OS) in MM patients with extramedullary disease (EMD).
Methods: The study included 32 patients with primary MM (17 males, 15 females) 23-77 years old (median value: 52 years old). The disease was diagnosed in accordance with the IMWG criteria (2014). 17 patients had EMD including 14 patients with soft-tissue plasmacytomas associated with bone and 3 patients with extramedullary foci in the neck area, in the stomach, in the liver. In all cases a tumour biopsy and bone marrow trephine biopsy were performed, that confirmed the presence of malignant plasma cell infiltration. Paraffin block slices from trephine biopsy material and tumour biopsy material were used to perform an immunohistochemistry (IHC) analysis with an antibody to CD56. Kaplan-Meier survival curves were generated, statistical analysis was done using the program «Statistica» ver.10.
Results: In patients with plasmacytomas the IHC analysis of trephine biopsy material showed $CD56^+$ in 59% cases *vs* 73,4% in patients without EMD. Five-year OS in patients with $CD56^+$ in the bone marrow was 90%, which was significantly higher (p=0,04) than that of the patients with $CD56^-$ - 0% with follow-up of 5 to 61 months (median 20 months, Figure1). Expression of CD56 on the surface of extramedullary MM cells was found in 76,5% patients. OS in the group of patients with $CD56^+$ in extramedullary MM cells and in bone marrow cells (n=9) was 67% which was significantly higher (p=0,04) than that in the group of patients (n=4) with $CD56^+$ in extramedullary MM cells and $CD56^-$ in bone marrow cells – 50%. Simultaneous lack of CD56 in extramedullary MM cells and in bone marrow cells was observed in 3 patients with 2 of them died of progression in 31 and 51 months. However simultaneous expression of CD56 in extramedullary MM cells and in bone marrow cells was observed in 9 patients with median follow-up of 40 months and 1 patient died of progression after 47 months.

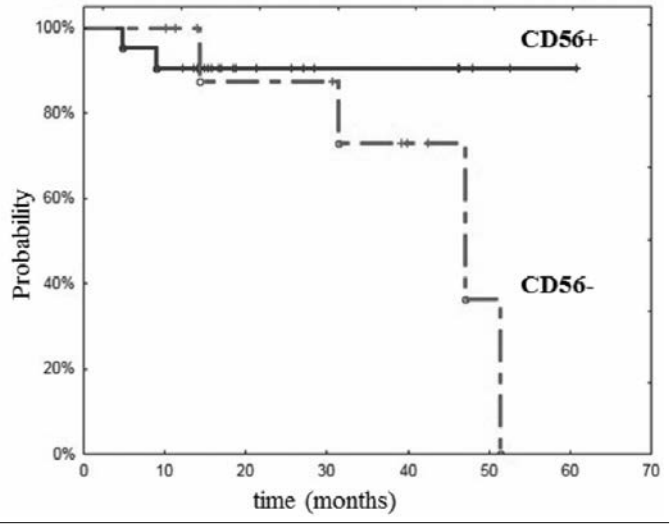

Figure 1. Probability of overall survival in patients depending on CD56 expression in bone marrow.

Summary/Conclusions: CD56 expression in bone marrow plasma cells significantly increases the OS rate in MM patients regardless the presence or absence of plasmacytomas. Double CD56 negativity both in extramedullary and bone marrow MM cells is a poor prognostic factor with high risk of early relapse and death.

PB2001

BENDAMUSTINE-BORTEZOMIB-DESAMETASONE IN THE MANAGEMENT OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA

C. Cerchione[1,*], L. Catalano[1], A. E. Pareto[1], S. Basile[1], L. Marano[1], I. Peluso[1], L. Simeone[1], O. Vitagliano[1], S. Palmieri[2], S. Rocco[2], F. Ferrara[2], F. Pane[1]
[1]Hematology, Ematologia e trapianto/au federico ii, [2]Hematology, AORN Cardarelli, Napoli, Italy

Background: Bendamustine is a bifunctional alkylating agent, with low toxicity, proved to be effective in relapsed, refractory and in new diagnosed Multiple Myeloma (MM).
Aims: It has been evaluated efficacy and tolerance of Bendamustine, in combination with bortezomib-dexamethasone (BVD) in patients with relapsed and refractory MM (rrMM), whose prognosis is particularly severe. A regional retrospective real-life analysis of patients with rrMM who had been treated with BVD as salvage therapy has been performed.
Methods:
56 patients (31 M/25 F, Table 1), with rrMM, median age at diagnosis 57.3 years (r. 36-82), median age at start of treatment 61.8 years (r.37-83) treated with several lines of treatments (median 6, r. 2-11), every refractory to all the drugs previously received (also Bortezomib), received BVD (Bendamustine 90 mg/sqm days 1,2; Bortezomib 1.3 mg/sqm days 1,4,8,11, Dexamethasone 20 mg days 1,2,4,5,8,9,11,12, Pegfilgrastim day +4) every 28 days, until progression. ISS was equally distributed, and cytogenetic was evaluable in 12 patients, and in particular one del13q and one t(11;14). All the patients had previously been treated with schedule containing bortezomib and IMIDs, and 30% had also received radiotherapy. 67% of them had undergone at least to a single auSCT. All patients were relapsed and refractory to last therapies received before BVD, including bortezomib.
Results: According to IMWG, after a median follow-up of 14 months (r.2-36), ORR was 64% (36/56 : 4 CR, 7 VGPR, 16 PR, 9 MR) with 8 PD and 12 patients in SD, which can be considered as an impressive result in this subset of rrMM patients. In particular, for 11 patients, BVD was, after having achieved at least a PR, a bridge to second auSCT, and for two patients a bridge to alloSCT. Median time to response was 1.2 months (r.1-3), median OS from diagnosis was 62.7 months (range 6-151), median OS from start of Bendamustine was 9.8 months (range 2-36).

Table 1.

Total patients	**56**
Male	31
Female	25
Median age, years	
at diagnosis, (range)	57.3 (36-82)
at start of BVD, (range)	61.8 (37-83)
Previous regimens	
median no. (range)	6 (2-11)
FISH analysis	**12/56**
negative	10
del13q	1
t(11;14)	1
Previous therapies : no. of patients/(%)	
Bortezomib	56 (100%)
IMIDs	56 (100%)
Autologous SCT	38 (67%)

Summary/Conclusions: BVD has shown significant efficacy in a particularly severe setting of patients, relapsed and refractory to all available therapeutic resources, and, in particular cases, it could be considered as a bridge to a second autologous or allogenic SCT.

PB2002

VE-CADHERIN IN MULTIPLE MYELOMA: AN INDEPENDENT PROGNOSTIC FACTOR FOR PROGRESSION-FREE SURVIVAL

B. Samura[1,2,*], Y. Kolesnyk[3], V. Syvolap[4], A. Abramov[5]
[1]Department of Hematology, Zaporizhzhia Regional Clinical Hospital, [2]Department of Internal diseases, [3]Department of Pathophysiology, [4]Department of Propedeutics of Internal Diseases, [5]Scientific medical-laboratory center, Zaporizhzhia State Medical University, Zaporizhzhia, Ukraine

Background: Endothelial damage and perivascular infiltrates are vital in the development of multiple myeloma. Recent studies have found that endothelial dysfunction might be result in multiple myeloma progression and adverse effects of drug implementation. On the other hand, there is a direct correlation between microvessel density in multiple myeloma and parameters of disease progression. Endothelial cells participate in inflammatory events leading to atherogenesis by regulating endothelial cell permeability via the expression vascular endothelial-cadherin (VE-Cadherin) on their surface. VE-cadherin is cell adhesion molecules localized at the endothelial junction, which plays critical roles in angiogenesis, neovascularization, neoplasm development, stem cells mobbing, and endothelial integrity. Indeed, VE-cadherin chiefly organizes the opening and closing of the endothelial barrier. It has found that VE-cadherin as a transmembrane protein probably modulates intensity of angiogenesis in multiple myeloma and may be useful in prognosis. However, the predictive role of VE-cadherin as a prognostic factor for survival of patients after treatment of multiple myeloma is not still clear.
Aims: We aimed to evaluate the prognostic value of circulating VE-catherin for progression-free survival in patients with multiple myeloma in complete or partial remission.
Methods: One hundred twelve out subjects with multiple myeloma were

enrolled in the study. Diagnosis and staging of multiple myeloma were defined by current clinical practice guidelines. To be achieving remission chemotherapy with bortezomib, thalidomide, dexamethasone, cyclophosphamide, melphalan, anthracyclines was used accordingly contemporary clinical guidelines. All subjects were at complete or partial remission at baseline. Observation period was up to 12 months. ELISA method for measurements of circulating level of VE-catherin was used.
Results: Medians of circulating levels of VE-catherin in subjects without progression of multiple myeloma (n=89) and subjects with progression (n=23) during 12 months were 0.92 ng/ml (95% confidence interval [CI]=0.66-1.19 ng/ml) and 1.77 ng/ml (95% CI=1.47-2.07 ng/ml) (p=0.0002). The best VE-catherin cutoff value for predicting disease progression risk was 1.31 ng/mL with AUC value 0.839 (p=0.0001), the sensitivity and specificity were 77.8% and 61.5% respectively. The presence of high levels of serum VE-cadherin was significantly correlated to a shorter progression-free survival (PFS). In a multivariate analysis along with clinical and biologic prognostic parameters, high serum VE-cadherin level (>1.31 ng/ml) was an independent adverse prognostic variable for PFS (median PFS 9.93 (IC=8.16-11.71) months *vs* 7.35 (IC=5.75-8.95) months (p=0.02).
Summary/Conclusions: The serum VE-cadherin level is a valuable biomarker for predicting treatment response and an independent prognostic factor for progression-free survival for patients with multiple myeloma.

PB2003

THE UTILITY OF FACS PURIFICATION OF PLASMA CELLS FOR FISH ANALYSIS IN MONOCLONAL GAMMOPATHIES

M. Pereira[1,2,*], G. Marques[3], J. Lima[3], R. Reis[3], A. Coelho[3], L. Jorge[3], S. Pedreiro[4], L. Ribeiro[1], A. Paiva[4], F. Rodrigues[3]
[1]Clinical Hematology Department, Coimbra University Hospital Centre, [2]Faculty of Medicine, University of Coimbra, [3]Clinical Pathology Department, [4]Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Despite the prognostic value of chromosomal aberrations, conventional metaphase karyotyping in monoclonal gammopathies (MG) is often uninformative due to the inherent difficulty of obtaining proliferating plasma cells (PC). Interphase fluorescence *in situ* hybridization (FISH) is a simple, quick and effective technique for the detection of cytogenetic aberrations that can overcome this limitation. However, the signal of interest is frequently diluted by the noise of the mixed cellularity of the sample, originating both false negatives and false positives. Fluorescence-activated cell sorting (FACS) of the target cells enables a focused application of FISH on pathologically significant cells – such as the PC in MG – reducing the confounding noise. This is particularly relevant when the percentage of pathologic cells in the sample is low, such as in monoclonal gammopathy of undetermined significance (MGUS) where, by definition, there are less than 10% PC in the bone marrow.
Aims: This study aims to analyze the utility and effectiveness of FACS purification of PC for the cytogenetic workup of MG by FISH.
Methods: We analyzed all FISH studies performed in our laboratory, in individual patients, on clonal interphase FACS-separated bone marrow PC, between the 1st June 2015 and the 15th September 2016. The probes used in our standard MG panel were del(1p32), amp(1q21), t(4;14) and del(17p13.1) (TP53 gene) and, starting in April 2016, t(14;16). We had previously established 20 000 cells per sample as the minimum (and sufficient) number of cells needed to guarantee the confident application of all 5 probes in our lab.
Results: After the exclusion of samples diluted with peripheral blood, we identified 102 patients with FACS separated purified PC. An average of 165 393±270 516 PC were separated per patient, and 98 of the cohort (96.1%) had a sufficient number of cells for the hybridization of at least one FISH probe; all 5 probes were applied in 30% of patients, 4 in 50%, 3 in 12% and 2 in 8%; the motives underlying the selection of fewer than all 5 probes in samples with a sufficient number (>20 000) of cells included the individual decision of the assisting physician and, for t(14;16), the date of the study. Considering only those studies performed after the introduction of t(14;16), all 5 probes were used in 67.5% of patients; we were able to apply four or more probes in 80% of patients with 1% or less bone marrow PC according to flow cytometry. The median age of the 98 patients with a FISH result was 63.6 years old (37.8 to 87.3), and 56.1% were male; 41.8% eventually received a diagnosis of MGUS and 58.2% of multiple myeloma (MM), with an identical median age (64.2±6.9 *vs* 63.0±10.8 years old, p=NS). We found that 16.3% (of 92) were positive for t(4;14), 12.2% (of 90) for del(17p13.1), 5.6% (of 90) for del(1p32) and 41.1% (of 90) for amp(1q21); t(14:16) was not identified in any of the 30 patients in whom the probe was used. The t(4;14) translocation was present in 22.4% of MM and 7.7% of MGUS patients (p=0.055), and del(17p13.1) was found in 18.5% *vs* 2.8% (p=0.026); on the other hand, both del(1p32) (5.6% *vs* 5.6%, p=NS) and amp(1q21) (46.3% *vs* 33.3%, p=NS) were identically distributed across diagnoses. We observed that 40.4% of MM and 65.8% of MGUS patients were positive for 20% of less of the tested aberrations, while 54.4% *vs* 34.2% were positive for 20 to 50%, and 5.3% *vs* 0% were positive for over 50% of the aberrations (p=0.026).
Summary/Conclusions: We have found that the application of FISH probes in FACS-separated PC is highly efficient with a robust yield, providing a large enough sample for the application of at least two probes in over 95% of patients, irrespective of bone marrow plasmacytosis; in fact, we obtained an average of 165 000 pure PC per patient, which is more than 8-fold higher than the number we consider invariably sufficient to apply 5 probes, which we achieved in at least 80% of patients.

PB2004

CLINICAL SPECTRUM AND EVOLUTION OF MONOCLONAL GAMMOPATHY ASSOCIATED NEUROPATHY *VERSUS* CHRONIC INFLAMMATORY DEMYELINATING POLYNEUROPATHY PATIENTS

J.M. Byun[1,*], I. Kim[2], S.-H. Baek[3], J.-J. Sung[2], Y. Koh[2], D.-Y. Shin[2], S.-S. Yoon[2], S. Park[4], C.-S. Kim[5]
[1]Seoul Metropolitan Government Seoul National University Boramae Medical Center, [2]Seoul National University Hospital, [3]Korea University Anam Hospital, Seoul, [4]Inje University Haeundae Paik Hospital, Busan, [5]Incheon Medical Center, Incheon , Korea, Republic Of

Background: Paraproteinemic neuropathy (PPN) refers to a disorder of the peripheral nervous system associated with a monoclonal gammopathy (MG). It is known that about 10% of idiopathic peripheral neuropathies are of this type. Unfortunately, PPN is often underdiagnosed or confused with chronic inflammatory demyelinating polyneuropathy (CIDP), subsequently leading to inappropriate management. Since progression of neuropathy is associated with possible malignant conversion of underlying monoclonal gammopathy, it is important to recognize underlying hematological conditions.
Aims: We aimed to determine whether the clinical characteristics and course differed in patients with PPN compared to those with CIDP in order to identify factors useful for differential diagnosis.
Methods: This study was carried out at Seoul National University Hospital, which is a tertiary academic center. During the period between January 2005 and December 2016, patients with 1) monoclonal gammopathy of undetermined significance (MGUS), and 2 CIDP were identified. Those with previous history of cancer or autoimmune disease requiring treatment with immunodulatory agents were excluded from analyses. In the end, a total of 18 MGUS patients and 34 CIDP patients, with complete set of data including clinical physical examinations, electrodiagnostic studies, and laboratory test results, were enrolled.
Results: In both groups, males were predominant. IgG MG was most common (55.6%) in our cohort. PPN appeared to be mainly sensory regardless of heavy chain or light chain. Compared to PPN patients, CIDP patients were associated with motor symptoms manifesting as motor weakness (50.0% *versus* 91.2%, P=0.001) and ataxia (44.4% *versus* 61.8%, P=0.043) (Table 1). There were equal number of axonal type neuropathy and demyelinating type neuropathy in patients with PPN, and there were no differences in type of neuropathy between various immunoglobulin subclasses. However, demyelinating type PPN was associated with more severe clinical presentations, including more dysethesia, pain and sensory symptoms. During median follow-up of 49 months, 2 PPN patients developed overt hematologic malignancies: 1 case of Waldenstrom macroglobulinemia and 1 case of AL amyloidosis. Both of them showed malignant transformation within 8 months of neuropathy development, and were associated with worsening neuropathic symptom at the diagnosis of hematologic malignancy. There were no differences between the two groups with regards to overall survival.

Table 1. Clinical characteristics of all enrolled patients.

	MGUS (n, %)	CIDP (n, %)	P
Total	18	34	NA
Age (mean, years [±SD])	67.6 (10.3)	57.8 (16.5)	0.027
Sex (male)	13 (72.2)	24 (70.6)	0.902
Ig type			
IgG	10 (55.6)	NA	NA

AZA/MMF	4 (22.2)	8 (23.5)	0.915
Treatment response			
Worsen	2 (11.1)	6 (17.6)	0.268
Stable	10 (55.6)	11 (32.4)	
Improved	6 (33.3)	17 (50.0)	

MGUS, monoclonal gammopathy of undetermined significance; CIDP, chronic inflammatory demyelinating polyneuropathy; NA, not applicable; SD, standard deviation; MRC scale, Medical Research Council scale for muscle strength; IVIg, intravenous immunoglobulin; AZA, azathioprine; MMF, mycophenolate mofetil.

Summary/Conclusions: Although both PPN and CIDP patients suffer from sensory symptoms, CIDP patients were more often associated with superimposed motor symptoms. Among PPN patients, demyelinating type neuropathy seems to be associated with more severe clinical presentations. Worsening of neuropathic symptoms in PPN patients warrants a high level of suspicion of malignant transformation of underlying disease.

PB2005

MOLECULAR GENETIC CRITERIA PREDICTING THE EFFICIENCY OF PERIPHERAL BLOOD HEMATOPOIETIC STEM CELLS TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA

Z. Minchenko[1], Z. Misharina[2], O. Dmytrenko[1], T. Liubarets[3,*], I. Dmytrenko[1], V. Khomenko[4]
[1]Immunogenetic Laboratory, National Research Center for Radiation Medicine of National Academy of Medical Science of Ukraine, [2]O.O. Bogomolets National Medical University, [3]Hematology and Transplantology Department, National Research Center for Radiation Medicine of National Academy of Medical Science of Ukraine, [4]Kyiv Bone Marrow Transplantation Center, Kyiv, Ukraine

Background: Global gains in treatment of MM using auto-PBHSCT testify to heterogeneity of long-term outcomes of transplantation - different term of the achievement and duration of complete remission, progression-free survival (PFS), overall survival (OS). These facts determine individual approach to the application of PBHSCT.
Aims: Finding molecular genetic criteria of predicting the effectiveness of autologous peripheral blood hematopoietic stem cell transplantation (auto-PBHSCT) for improving of algorithm of multiple myeloma (MM) patients cure at various stages of treatment.
Methods: The study involved 61 patients with MM with relapse and primary therapy resistant patients. Molecular cytogenetic, immunogenetic, hematological and statistical methods were used.
Results: Since appearance of genetic abnormalities in the malignant plasma cells is one of the pathogenic mechanisms of the disease, genetic support of patients is essential. It was determined that the carriage of the allele HLA-DQB1*03: 02 in MM patients is associated with a high risk of high-dose chemotherapy resistance (F=4,83, p=0,028; OR=1,75, p=0.038), and achieving remission after auto-PBSCT is associated with carriage of haplotype HLA-C *06 - HLA-DQA1*01: 01 (F=4,87, p=0,028; OR=7,34, p=0,05). Abnormalities of chromosomes 4, 11, 13, 14, 16 and 17 were determined in 35 of 61 (57%) MM patients with complicated disease course and minimal therapy response. Significant alterations were revealed in the presence of two or more abnormal clones (23 patients (37,7%), Ro Spirman=0,42, p <0,05), deletion of chromosome 17 (17 patients (27,9%), Ro Spirman=0,41, p <0,05) , deletion/monosomy of chromosome 13 (10 of 15 patients surveyed, Ro Spirman=0,33, p <0,05), the translocation t(4;14) (4 patients (6,6%), Ro Spirman=0,50 , p <0,02).
Summary/Conclusions: The results indicate the necessity of introducing the molecular genetic support into protocol of examination MM patients on various stages of treatment with auto-PBHSCT.

PB2006

THE INFLUENCE OF MINIMAL RESIDUAL DISEASE AND TUMOR LOAD ON THE PROGRESSION FREE SURVIVAL IN MULTIPLE MYELOMA PATIENTS

A. Garifullin[1,*], S. Voloshin[1], A. Kuvshinov[1], Z. Chubukina[1], A. Schmidt[1], S. Bessmel'tsev[1], A. Chechetkin[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Use of modern drugs and their combinations in the complex antimyeloma therapy (induction, high-dose therapy (HDT) with autologous stem cells transplantation (ASCT), consolidation and maintenance therapy) to improve efficacy of treatment and duration of responses. Despite the achievement of complete response (CR) many patients has a relapse which is caused by activation of residual clonal plasma cells.
Aims: To define influence of induction therapy regimens, HDT with ASCT to the frequency of Minimal Residual Disease (MRD) negative status and estimate a role MRD in duration of Progression Free Survival (PFS) in multiple myeloma (MM) patients.
Methods: We analyzed 52 patients with MM (median age 55 years, male/female – 2.1:1). The induction therapy with Bortezomib-based regimens (VD, CVD, VMP, PAD) was used in 36/52 (69%) patients, Immunomodulator-based regimens (Thal+D, RD, VRD, PomD) – in 14/52 (27%), chemotherapy – in 2/52 (4%). ASCT is carried out 31 (59.6%) patients. Primary tumor cells phenotype and MRD were detected by 5-color flow cytometry. Clonal plasmatic cells were detected by markers: CD38, CD138, CD45, CD19, CD20, CD27, CD56 and CD117. MRD-negative status considered in identifying less than 1 tumor cell in 10000 (0.01%).
Results: MRD-negative CR was reached in 23.8% (10/42) patients after 4-6 cycles of therapy. The frequency of MRD-negative status in the "Bortezomib group" was 31% (9/29), in the "Immunomodulator group" - 7.7% (1/13) (Chi-square =0.1; *p >.05*). The general frequency of MRD-negative CR after HTD with ASCT was 33.3% (7/21). The carrying out HTD with ASCT allowed to MRD eradication in 36.4% (4/11) patients. One patient with a "light chain" myeloma lost MRD-negative CR after HTD with ASCT that led to development of a clinical relapse after 6 months. Carrying out a maintenance therapy with bortezomib or lenalidomide didn't allow to achieve MRD-negative status. Carrying out a maintenance therapy with bortezomib or lenalidomide didn't allow to achieve MRD-negative status in patients with MRD-positive response. On the contrary, achievement MRD-negative status promoted to increase of PFS. The PFS median in MRD-positive group of patients (n=36: 21 CR, 6 VGPR, 9 PR) was 21 months, in the MRD-negative group (n=16) – 66 months (p=.0068). The PFS median patients with CR was higher in the MRD-negative group than in the MRD-positive group (66 and 48 months, respectively, p=.0045). The tumor load is also a strong prognostic factor like MRD status. Patients who attained low-level MRD had of benefit in the duration of PFS: <0.01% - 66 months, 0.01%>0.1% - 48 months at, 0.1%>1% - 22 months, >1% - 10 months (p=.0009) (Figure 1).

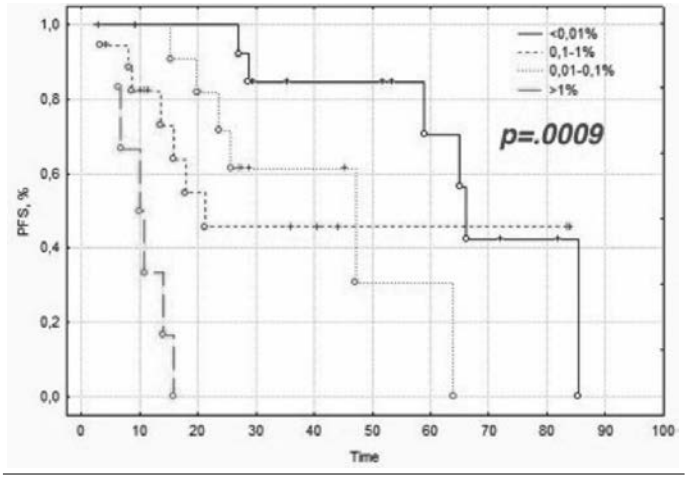

Figure 1. The influence of tumor load on progression free survival.

Summary/Conclusions: The frequency of achievement MRD-negative doesn't depend from program of induction therapy, HDT with ASCT and maintenance therapy. Negative prognostic role of MRD status independent from clinical response. Presence of MRD after treatment to associated with decrease of PFS and early relapse. Control of MRD allows to increase of PFS and can be done by means of modern drugs and its combinations, HDT with ASCT and maintenance therapy. Impact of MRD requires further studies, especially after HDT with ASCT.

PB2007

QUALITY OF RESPONSE AS PREDICTOR OF SURVIVAL AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN REAL LIFE MULTIPLE MYELOMA PATIENTS IN A SINGLE INSTITUTION

A. Pinto[1,*], A. Roque[1,2], E. Cortesão[1,2], A. Espadana[1], A. B. Sarmento[1,2], C. Geraldes[1,2], M. L. Ribeiro[1]
[1]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, [2]Faculty of Medicine and Cimago, University of Coimbra, Coimbra, Portugal

Background: High dose chemotherapy (HDC) followed by autologous stem cell transplantation (ASCT) is the standard treatment approach for younger patients with multiple myeloma (MM). Since the introduction of proteasome inhibitors and immunomodulatory drugs in MM treatment more patients achieve deep and durable responses and better disease control before ASCT.
Aims: To evaluate the association between the depth of response before ASCT and survival outcomes in a cohort of patients with MM.
Methods: Retrospective analysis of patients with MM treated with HDT and ASCT between 2007 and 2016 in a single institution. All patients received peripheral blood stem cell support after conditioning with high dose melphalan (200 mg/m^2 and 140mg/m^2 for patients with renal insufficiency). Response was assessed 100 days after ASCT according to the International Myeloma Working Group response criteria. The Kaplan-Meier method was used to estimate progression free survival (PFS) and overall survival (OS) and comparison between risk groups was performed by using the log-rank test. The prognostic factors of survival were analyzed by Cox regression univariate and multivariate analysis.
Results: We included 195 MM patients, mainly males (57.9%) with a median age at ASCT of 61 years (28-71). The most prevalent subtype was IgG k (44.1%). The median number of previous therapeutic lines was 1 (1-4) and the majority of patients (61%) received bortezomib as part of first-line regimen. Patients undergone ASCT within a median of 10 months after diagnosis. With a median follow-up time from ASCT of 28.55 months (2.8-121.4), OS at 2 and

5 years was 83.8% and 68.9% and PFS was 74.8% and 37.3%, respectively. Before ASCT, 101 patients (51.8%) achieved very good partial response (VGPR) or better (≥VGPR) and 94 patients (48.2%) a partial response (PR). The patients in ≥VGPR presented significantly longer OS (median OS not reached *vs* 96.9 months, p=0.023) and PFS (58.5 *vs* 41.2 months, p=0.003) compared with those in PR. At 100 days after ASCT, 107 patients (54.9%) presented ≥VGPR, 79 (40.5%) PR and 7 (3.6%) progressive disease. Two patients were not assessed due to loss of follow-up. The group of ≥VGPR showed superior OS (median OS not reached *vs* 72.4 months, p=0.023) and PFS (58.5 *vs* 34.79 months, p=0.007) compared to the PR group. We did not found statistically significant differences in survival of patients who achieved ≥VGPR before or after ASCT. Univariate analysis indicates that depth of response before and after ASCT (≥VGPR *vs* PR) are significant predictors of OS (HR 0.49; 95% CI 0.31-0.80, p=0.004 and HR 0.49; 95% CI 0.30-0.81, p=0.005) and PFS (HR 0.50; 95% CI 0.27-0.92, p=0.026 and HR 0.49; 95% CI 0.27-0.90, p=0.021). Multivariate Cox regression model showed that these factors retain their prognostic value after adjustment for age, International Staging System stage and number of previous lines of treatment.

Summary/Conclusions: These findings provide evidence for quality of response as a predictor of OS and PFS after ASCT in patients with MM. Outcome after ASCT seems to be better for MM patients who achieve deep responses (at least VGPR) before or after transplant. Our results support the use of more effective induction regimens in order to improve initial response as this may correlate with higher response rates and survival post-ACST.

PB2008

LEPTOMENINGEAL INFILTRATION SCREENING SHOULD BE PERFORMED IN PATIENTS DIAGNOSED WITH PLASMA CELL LEUKAEMIA

M.Q. Salas[1,*], V. Clapes[2], N. Garcia[1], C. Baca[3], R. Velasco[4], E. Gamundi[5], A. Sureda[3]
[1]Hematology, ICO-Hospitalet, [2]Hematology, ICO Duran i Reynals, [3]Hematology, ICO-Duran i Reynals, [4]Neurology, [5]Hematology, Hospital Universitario de Bellvitge, Barcelona, Spain

Background: Plasma cell leukaemia (PCL) is a rare and aggressive plasma cell (PC) disorder characterized by the presence of circulating plasma cells. PCL can either originate *de novo* (pPCL) or as secondary PCL (sPCL) in patients with relapsed/refractory multiple myeloma (MM). PCL has a more aggressive clinical presentation than MM with a more frequent extramedullary involvement, such as leptomeningeal infiltration. However, because of the low incidence of this entity, most clinical data come from small retrospective studies. Classical diagnosis criteria of PCL are today under review and the incidence of leptomeningeal infiltration is unknown.

Aims: We aimed to study the clinical features with special emphasis in the incidence leptomeningeal infiltration in patients diagnosed with PCL in our centre.

Methods: Seventeen patients were diagnosed of PCL between 2008 to 2016 in our centre. PCL was defined based on criteria from the Chronic Leukaemia Myeloma Task Force, by the presence of 2x109/L peripheral blood PC or plasmacytosis accounting for more than 20% of the differential white cell count. Medical records were retrospectively reviewed. Clinical response was evaluating per IWMG criteria. Clinical and biological features, progression free survival (PFS) and overall survival (OS) were analyzed. Survival curves were estimated using the Kaplan-Meier method and compared using the Log-Rank test.

Results: Seventeen patients with PCL were included. Six (35.3%) were pPCL and eleven (64.7%) sPCL. Median age at diagnosis was 57 years (range 35-78) and 8 (47.1%) were males. Clinical and analytical features at the moment of diagnosis are recorded in Table 1.

Table 1.

Clinical characteristics:	
Durie-Salmon stage	
I	2 (11.1%)
II	2 (11.1%)
III	13 (76.1%)

Hyponatremia	
Yes	9 (52.9%)
Hypocalcitoemia	
Yes	5 (29.4%)

Five (29.4%) patients presented with leptomeningeal infiltration; in three of them it was diagnosed at the time of the diagnosis of PCL. All the patients had neurological features. Thirteen (76.4%) patients were able to start a curative treatment: VD in 7 (53.8%) patients, VTD in 2 (15.4%), VAD in 1 (7.7%), D-PACE in 1, MTX-ARAC in 1 patient and RD in the remaining one. Three patients received intrathecal treatment. The intention-to-treat response was: 2 (15.4%) CR, 2 PR, 7 (53.9%) refractory disease/progression and 2 non-evaluable. Only 2 (15.4%) patients achieved enough response (2 CR) to undergo an autologous stem cell transplant (ACST) and only 1 to undergo an allogenic-SCT. With a median follow up of 4 months for all the patients inclosed, median of PFS was 3 (CI 95% 0.47-4.76) months and median of OS was 4 (IC 95% 0.47-7.53) months.

Summary/Conclusions: Prospective multicenter studies are required to provide a better understanding of the pathogenesis of PCL.Staging procedures should include lumbar puncture or magnetic resonance at diagnosis when extramedullary involvement is suspected. Intrathecal prophylaxis with cytarabin, metotrexate and dexamethasone is not today a standard of care for patients with PCL.

PB2009

MANAGEMENT AND OUTCOMES OF PATIENTS WITH MULTIPLE MYELOMA IN REAL-WORLD SETTINGS IN BULGARIA, CROATIA AND SLOVAKIA

G. Mihaylov[1,*], S. Ostojić Kolonić[2], Z. Stefanikova[3], L. Fink[4], M. Hemetsberger[5], K. Bjorklof[6], K. Szabolcs Toka[6], F. Gatta[6], D. Niepel[7]
[1]Clinic for Hematology, University Hospital Sofia, Sofia, Bulgaria, [2]School of Medicine, Merkur University Hospital, Zagreb, Croatia, [3]Department of Hematology and Transfusiology, University Hospital, Bratislava, Slovakia, [4]Kantar Health, Paris, France, [5]Hemetsberger medical services, Vienna, Austria, [6]Amgen (Europe) GmbH, Zug, Switzerland, [7]Amgen (Europe) GmbH, Vienna, Austria

Background: The multiple myeloma (MM) treatment (Tx) landscape is rapidly evolving, with varying Tx practice patterns and access schemes across countries. However real-world (RW) data describing patient (pt) management, MM Tx use and outcomes in some Eastern European Countries are limited.

Aims: To understand the characteristics, management, Tx patterns and outcomes of pts with symptomatic MM in a RW setting in Bulgaria (BG), Croatia (HR) and Slovakia (SK).

Methods: Data were collected within a cross-sectional (X) and retrospective (R) phase of a chart review in 6 countries between June/15 and June/16 by (onco-)hematologists who managed at least 15 pts with MM per month (mo) and were responsible for initiating MM Tx. Data from 3 countries with limited access to MM Tx are shown. In the X-phase, data included characteristics and current Tx by line of therapy for all pts with MM seen during a 3-week observation period, regardless of pts' Tx status and strategy. In the R-phase, data included pt and disease characteristics at diagnosis, Tx response, comorbidities and clinical outcomes by Tx line. Pts were selected in reverse chronological order and those who had completed specific lines of active Tx within the past 3 mo were included as follows: 3 pts in first line (1L), 4 pts in second-line (2L) and 7 pts in third or higher lines. Analyses were descriptive.

Results: In the X-phase, 7 physicians from BG, 6 from HR and 5 from SK included 84, 89 and 56 pts respectively. In BG, HR and SK respectively, 45%, 51% and 52% of pts were <65 years; 41%, 35% and 38% were 65–75 years. Only 4 pts (from BG) were enrolled in clinical trials. Median time since diagnosis was 24, 31 and 54 mo in BG, HR and SK respectively. In BG, fewer pts received stem cell transplantation (SCT) than in HR and SK (8% *vs* 24% and 36%). The proportion of pts that had received SCT at any point increased from 1L to 2L (3% to 19%, 7% to 35% and 9% to 54% in BG, HR and SK respectively). 82% of pts in BG, and 70% both in HR and SK were currently receiving Tx (Table 1), while 17%, 30% and 25% of pts respectively, were treated previously. Only 4 pts (1 in BG and 3 in SK) had never been treated. In the R-phase, 6 physicians from BG, and 5 from each of HR and SK included 43, 39 and 44 pts respectively. In BG, HR and SK respectively, 44%, 41% and 41% of pts were <65 years; 49%, 36% and 39% were 65–75 years. Depth of response, as assessed by physicians, decreased in BG with each additional line of Tx, but remained stable or increased in HR and SK: 43%, 55% and 50% of pts achieved at least a very good partial response (≥VGPR) in 1L, while 13%, 54% and 69% of pts achieved ≥VGPR in 2L. The most common (≥20%) adverse events (AEs) and comorbidities in 1L were anemia (23% in HR, 43% in SK) and neutropenia (43%) and thrombocytopenia in SK (21%). Mostly, these AEs did not impact on Tx.

Summary/Conclusions: These findings suggest a high unmet need for access to more effective and innovative Tx options with manageable safety profiles in these countries. In particular, in BG where bortezomib- and chemotherapy-based regimens are the only treatments used, pts might be re-treated with the same agents, which may explain why most do not achieve ≥VGPR from 2L. In HR and SK, sustained or increased rates of ≥VGPR in 2L may be due to the use of newer or different agents from those used in 1L and to the fact that most pts had previously received a SCT. These RW data provide useful input for economic evaluations of new MM agents to include in earlier Tx lines in these countries.

SINGLE SHOT MEDIUM DOSE MELPHALAN IN RELAPSED MM PATIENTS: A RETROSPECTIVE, SINGLE CENTER EXPERIENCE

C. Clissa[1,*], A. Isidori[1], F. Loscocco[1], E. Gabucci[1], L. Malerba[1], B. Guiducci[1], G. Visani[1]
[1]Hematology, AORMN Pesaro, Pesaro, Italy

Background: Multiple myeloma (MM) patients refractory to proteasome inhibitors, IMIDs or both, have an extremely poor prognosis. Moreover, they frequently fail to respond to further therapies, and represent a major challenge in everyday clinical practice.
Aims: With this in mind, we treated 12 patient with relapsed MM with a single shot of medium dose melphalan (60 mg/m2) between October 2010 and January 2016.
Methods: The median age was 72 years (range, 62 – 79) and the median time from initial diagnosis until melphalan treatment was 51 months (range, 24 – 144). Patients were heavily pretreated with a median number of 3 prior lines of therapy. All patients were refractory to the previous therapeutic regimens and had failed to respond or were refractory to regimens containing bortezomib. Seven patients (84%) had previously received at least one IMiD, 8 (67%) autologous stem cell transplantation (ASCT) and 1 allogeneic stem cell transplantation. The patients included in the series were not eligible for any clinical trial available at the Institution. All patients gave informed consent.
Results: All patients had cytopenia (anemia, neutropenia and thrombocytopenia). We observed 3 cases of gastrointestinal toxicity (1 bleeding, 1 subocclusion, 1 mucositis grade IV sec. WHO), 3 cases of clinically documented infection (1 Escherichia coli bacteremia, 1 fever of unknown origin, 1 erysipela) and 2 deep vein thrombosis. Response was assessed between six and eight weeks after melphalan therapy. Overall, 10 out of 12 patients had a response (1 complete response, 3 very good partial response, 2 partial response and 4 stable disease); only 2 had progressive disease. Median overall survival was 11 months (range, 2 -37). 10 of 12 patients relapsed after a median time of 5 months (range: 2-12). Concerning two patients not relapsed, 1 patient died in partial response 8 months after therapy of other causes; 1 patient is still alive, in complete remission 18 months after melphalan. He underwent ASCT and maintenance with lenalidomide.
Summary/Conclusions: Many patients refractory to proteasome inhibitors and IMiDs are probably still sensitive to alkylating agents and could be rescued with medium dose melphalan. We suggest therefore melphalan as a "bridge" strategy for further therapy, particularly in patients needing immediate disease control. Even in this era in which several novel drugs became available, single shot medium dose melphalan could be an affordable and safe therapy, able to control aggressive relapse, and to reduce disease burden prior to targeted therapy.

PB2011

LENALIDOMIDE AT THE DOSE OF TWENTY-FIVE MG EVERY OTHER DAY IN PATIENTS AFFECTED BY MULTIPLE MYELOMA AND RENAL FAILURE: A REAL-LIFE EXPERIENCE

C. Cerchione[1,*], L. Catalano[1], A.E. Pareto[1], D. Nappi[1], I. Peluso[1], K. Ferrara[1], M. Di Perna[1], I. Zacheo[1], F. Pane[1]
[1]Hematology, Ematologia e trapianto/au federico ii, Napoli, Italy

Background: Lenalidomide, available as oral compound, is an IMiD with both antiproliferative and immunomodulatory activity which is largely used in the management of newly diagnosed, relapsed or refractory MM and as maintenance therapy after autologous stem-cell transplantation. Due to its renal route of excretion, it is mandatory to adjust lenalidomide dose in patients with RI, guided by Creatinine Clearance (ClCr), in order to impede a systemic prolonged exposure that could boost myelosuppression. With normal renal function, lenalidomide reaches its maximal plasma concentration after a median time of 0.6-1.5 h, and it is cleared by glomerular filtration and active tubular secretion in 3 to 4 hours. Serum half-life increases up to 9 hours if moderate/severe renal impairment is present (creatinine clearance <50 or <30 mL/min, respectively). In the latter cases a reduction of the daily dose is recommended. Dose adjustment based on RI severity decreases the daily amount of lenalidomide from 15 up to 5 mg (in patients undergoing dialysis); other studies include a schedule with 10 or 15 mg every other days. However, there is no theoretical assumption against the possibility that protracting the time of full standard doses can be equally effective and tolerated by patients requiring reduced doses.
Aims: In this report, we describe our retrospective experience on the administration of lenalidomide 25 mg every other day for patients with MM and RI.
Methods: From March 2014 to February 2016, 19 consecutive patients, 11 female and 8 male, with a median age of 63.3 years (range: 49-81) affected by advanced, resistant and progressive MM (median number of previous treatment lines: 3, range : 1-5, all including bortezomib) with concomitant renal failure not in dyalitic support (median calculated ClCr 36.4 ml/min, range : 18-66) were treated, after informed consent, with monthly 21-day courses of 25 mg lenalidomide every other day and dexamethasone (20-40 mg on days 1-8-15-22, every 28 days).
Results: Disappearance of urinary light chain and reduction of serum creatinine (complete response) were detected in 7 patients (36.8%); 3 patients (15.7%) had a very good partial response, 3 (15,7%) had a partial response, 4 of them (21.0%) were in stable disease, whereas 2 patients (10.5%) had signs of progressive disease. Overall response ratio was 68.2%. More than half of the patients (11/19, 57.8%) had a renal response (median calculated ClCr 51.5ml/min, range 20-148). Median progression free survival was 8 months (range 3-18 months). No patient experienced grade 4 myelotoxicity; four patients required red cell transfusions for grade 3 anemia. No SAE occurred during treatment.
Summary/Conclusions: Dose adjustment RI-related of Lenalidomide is recommended in most guidelines, but there is not a leading scheme with a proven effectiveness more than others.These preliminary observations point to a significant therapeutic effect of lenalidomide, at the dose of 25 mg every other day for 21 days, in more than half of a small population of patients with advanced MM and renal impairment, with not negligible logistic and economic advantages. However, these results should be validated by controlled studies involving larger number of patients.

PB2012

A FEASIBILITY-STUDY ON IMPLEMENTATION OF THE INTERNATIONAL MYELOMA WORKING GROUP RECCOMENDATIONS FOR MULTIPLE MYELOMA PATIENTS IN ROUTINE CLINICAL PRACTICE: A PERIPHERAL CENTER EXPERIENCE

M. Torchio[1,*], C. Cavalli[1], A. Gazo[2], R. Bellazzi[2], M. Danova[1]
[1]Internal Medicine and Medical Oncology, [2]Nephrology and Dyalisis , Ospedale Civile di Vigevano, ASST di Pavia, Vigevano, Italy

Background: Renal impairment (RI), defined as serum creatinine above upper normal limit or >2 mg/dl or a estimated glomerular filtration rate (eGFR) <60 ml/min/1,73m2, is one of the most common complications of MM, and it is associated with an increased risk of early death. The incidence of RI at MM diagnosis ranges from 20% to 50%, while its comparison occurred in 60% MM patients (pts). In this scenario tempestive diagnosis of RI in MM pts and exclusion of possible alternative causes of RI (like amiloydosis, diabetes or MIDD) are essential.
Aims: We applied a diagnostic algorithm obtained from the International Myeloma Working Group Reccomendations in pts admitted to our department for RI (with known and unknown MM, or suspected cast nephropathy, CN), in order to investigate if this diagnostic workflow could positively impact on MM pt management.
Methods: We enrolled adult pts, known or unknown MM, admitted to our hospital for RI or suspected CN, with or withouth monoclonal component. Primarly, we performed complete blood analysis, with eGFR (CKD-EPI and MDRD methods), serum and urine electrolites, bicarbonatemia, serum and urine immunofixation, fraction 3 and 4 of complement, crioglobulinemia, HbA1c, arterial gas analysis, evaluation of urine rate every 6 hours, daily urine collection, urine sediment. We also collected anamnesis on eventual nephrotoxic concomitant therapies like ASA, FANS, clinical parameters and objectives signs of RI (edema, symptomatic disionia). On the second day of hospitalization we requested protein electrophoresis on serum and urine, chest X-ray, ultrasonography of abdomen, ecocardiography and electrocardiography. On the day three we evaluated results of previous exams and we decided, if necessary, eventual biopsieson (bone marrow in suspected unknown MM pts, renal in suspected CN pts, umbilical fat for amyloidosis). All analyses were daily and collegialy discussed between Internists and Nephrologists.

Results: From March to December 2016 we admitted 57 pts with RI and monoclonal component (29 F, 28 M, 41-83 yrs range), 20 are known MM pts and 37 de novo pts. We diagnosed 11 de novo MM, 13 knowed MM with a de novo RI, 12 diabetes related RI, 3 amyloidosis, 16 other causes.
Summary/Conclusions: The implementation of the International Myeloma Working Group Reccomendations in a routine clinical practice confirmed its feasibility and utility in the optimal workout of MM pts. We obtained diagnosis of RI within 4 days, both in known and in de novo MM pts, with a positive impact on reduced hospitalization, uncessary dyalisis and steroids overtreatment.

PB2013

NOCARDIOSIS PROVOKED BY NOVEL AGENTS AT RELAPSED MULTIPLE MYELOMA:CASE SERİES

Z. Bolaman[1,*], A. Turgutkaya[1], E. Ceylan[2], B. Gültekin Korkmazgil[3], M. Telli[3], C. Karaman[4], I. Yavasoglu[1]
[1]Adult Hematology, [2]Pulmonology , [3]Microbiology, [4]Radiology, Adnan Menderes University Medical Faculty, Aydin, Turkey

Background: The proteosome inhibitors and immunmodulatory drugs which are used in MM treatment enhance the risk of infection by several mechanisms.Nocardial infections are rare in Turkey.
Aims: Here,we present three relapsed myeloma cases which developed nocardia pneumonia.
Methods: Case-1 :66 year old man, who has a history of autologous SCT 4 years ago and lenalidomide usage because of IgG kappa type myeloma, has been prescribed bortezomibe for the relapse of the disease.He was immunocompromised not only because of the myeloma, and also because of the diabetes and renal failure without dialysis. He was admitted to the hospital because of the productive cough.His lymphocyte count was 1290/mm3 and flow-cytometric analysis showed CD5:%68 and CD20:%2. Thorax CT showed 39x39x45 mm mass like lesion.Broncoscopic lavage examination showed branched bacillus via modified acid-fast and Gram stain.This typical morphological appearence was defined as Nocardia spp. Imipenem/cilastatin treatment started and control CT was performed after ten days and it showed regression of the infiltration.He was discharged with oral TMP/SMX antibiotherapy. Case-2:71 year old woman,who has a history of two auotologous SCT 12 and 5 years ago because of IgG kappa type myeloma;admitted to the hospital with productive cough during pomalidomide treatment.Her lymphocyte count was 2300/mm3 and flow-cytometric analysis showed CD5:%88 and CD 20:%1.HRCT showed a 7x6x6 cm sized mass like lesion with a cavity.Branched Gram positive bacillus (Nocardia sp.) was detected from broncoscopic specimen analysis,so imipenem-cilastatin therapy has been started.She responded well to therapy and was discharged with TMP/SMX antibiotherapy. Case-3:72 year old man,who has a diagnosis of IgG kappa type myeloma and a history of autologous SCT 4 years ago following bortezomibe treatment,relapsed 5 months ago. He has been admitted to the hospital with nonproductive cough complaint under the treatment of lenalidomide and dexamethasone.His lymphocyte count was 520/mm3.Flow-cytometric analysis couldn't be performed.Thorax CT showed 4 cm sized cavity and sputum microscopy showed acid rezistant branched bacillus thought to be consistent with nocardiosis.The imipenem/cilastatin and TMP/SMX treatment have begun and 12 days later, a control CT was performed and showed regression.He was discharged with oral TMP/SMX antibiotherapy.
Results: See Table 1 and Figure 1.

Table 1.

Genereal features of the cases	Case -1	Case-2	Case-3
Age	66	71	72
Gender	Male	Female	Male
Lymphocyte Count(/mm³)	1290	2300	520

Recent Treatment Before Nocardiosis	Bortezomibe	Pomalidomide	Bortezomibe-Thalidomide-Dexamethasone

Case-1: A mass like infiltration at right lung superior lobe posterior segment suggesting Nocadia

Figure 1.

Summary/Conclusions: The proteosome inhibitors and immunmodulatory drugs which are used for the treatment of MM;make T cell disfunction and considering B cell disfunction is also present because of the nature of the disease;this situation tends to provoke rare opportunistic infections such as nocardiosis.Thus,in these patients;it is significant to follow the lymphocyte count closely and to keep in mind that kind of rare microorganisms.

PB2014

LENALIDOMIDE IN PATIENTS WITH DIALYSIS-DEPENDENT END STAGE RENAL FAILURE (ESRF) AND MULTIPLE MYELOMA

P. Di Ciaccio[1,*], S. Ling[1]
[1]Department of Haematology, Liverpool Hospital, Sydney, Australia

Background: Lenalidomide is an oral immunomodulatory medication with clinical efficacy in relapsed/refractory and treatment naïve multiple myeloma (MM), 5q- myelodysplasia and lymphoma. Lenalidomide is eliminated predominantly unchanged by urinary excretion. Renal impairment is common in MM (15-40%) and approximately 10% of MM requires dialysis. However, there is a paucity of clinical safety data of Lenalidomide in ESRF. There is evidence that Lenalidomide can be safely used in patients with moderate and severe renal dysfunction with dose adjustment. However, published data in hemodialysis-dependent patients is limited to a handful of patients across small retrospective analyses and case reports. Patients with ESRF have generally been excluded from clinical trials investigating Lenalidomide. Phase III trials in the relapsed setting (MM-009, MM-010) excluded patients with a serum creatinine >221µmol/L. The FIRST trial (MM-020), investigating upfront use, excluded patients dependent on dialysis. There is no accepted clinical standard on the most appropriate dosing of Lenalidomide in dialysis. The manufacturer has provided guidelines, being 5mg daily, day 1-21, every 28 days (equivalent to 105mg per cycle). There is alternate well-cited pharmacological data that the more appropriate starting dose is likely 15mg, three times per week, given post-dialysis (equivalent to 135mg per cycle). **Aims:** To provide real-world evidence of an institutional experience of the use of Lenalidomide in dialysis-dependent MM.
Methods: We performed a retrospective audit of our in-centre experience with treating dialysis-dependent MM with Lenalidomide and included patients who completed at least one cycle of therapy. Patients were assessed for haematological toxicity, significant infective complications, thrombosis, disease response and progression-free survival. Best response was stratified by IMWG criteria. Patients' baseline characteristics, prior therapies, cytogenetics and FISH data were collected.
Results: We identified 5 patients treated between 2010 and 2017, aged between 54 to 73 years old. All patients had relapsed/refractory MM and dialysis dependent ESRF. The median number of prior therapies was two. One patient had t(11,14) on FISH and died from progressive disease. Dose schedules are shown in the Table 1. Almost all patients experienced grade III-IV haematological toxicity and 60% had grade III-IV infection. There was a positive correlation between dose and toxicity, and furthermore there appeared to be an inverse relationship between age and tolerated dose. Haematological toxicities and infection were ameliorated by dose adjustment in most instances. There was no drug related mortality, however one patient died of progressive disease. Four of the five patients were prescribed aspirin thromboprophylaxis, with no proven thrombotic complications seen. Where possible to assess, the ORR was 75% (3/4), with 2 patients achieving a very good partial response (VGPR), 1 partial response and 1 progressive disease. The lowest starting dose in this cohort was 10mg twice/week and the maximum dose was 25 mg three times/week.

Table 1.

	Age	Dose Schedule	Cumulative Dose/cycle	Number of Cycles	Grade III/IV Neutropenia	Grade III/IV Anaemia	Grade III/IV Thrombocytopenia	Clinically Significant Infection	PFS (months)	Response
Patient 1	63	15mg three times weekly	135mg	12	Yes	No	No	No	9	VGPR
Patient 2	54	i) 25mg three times weekly ii) 25mg twice weekly iii) 25mg three times weekly	225mg 150mg 225mg	26 36 8	No No Yes	No No No	No No Yes	Yes No Yes	85	VGPR
Patient 3	67	i) 25mg twice weekly ii) 10 mg twice weekly	150mg 60mg	13 21	Yes No	Yes No	Yes No	Yes Yes	48	Partial Response
Patient 4	73	10mg twice weekly	60mg	2	Yes	No	No	Yes	2	Disease Progression
Patient 5	46	5mg daily	105mg	1	§	§	§	No	¶	¶

§ Disease-related pancytopenia ¶ Too early to assess

Summary/Conclusions: Our experience builds on the emerging evidence that reduced dose of Lenalidomide can be safely prescribed for dialysis-dependent MM, with clinical efficacy. In our cohort most patients took Lenalidomide on days of dialysis only. There was significant variation of dose-related tolerability between patients. However, toxicity was manageable with diligent monitoring and dose adjustment.

PB2015

STUDY USE OF 18-F FDG PET / CT SCANNING INTO THE FIRST FOLLOW UP OF PATIENTS WITH MULTIPLE MYELOMA AND ASSOCIATION WITH BIOCHEMICAL RESPONSE

K. Vallejo Luna[1], M. Simó[2], J. Montoro[3], C. Palacio[3], M. Junquera[4], M. Gironella Mesa[4,*]
[1]Hematology, Vall d'Hebron Institute of Oncology, [2]Department of Nuclear Medicine, [3]Department of Clinical Diagnostic, [4]Department of Hematology, Hospital Universitario de Vall d' Hebron, Barcelona, Spain

Background: Positron computed tomography (PET / CT) with ^{18}F fluorodeoxyglucose-labeled glucose (FDG) is a reliable technique with high sensitivity and specificity for assessing skeletal involvement and recent studies propose it as a method for predicting treatment response in multiple myeloma. Conventionally, the response is measurable by the monoclonal component in both serum and urine and Minimal residual disease (MRD) by flow cytometry has been established as a mandatory tool. The studies are aimed at combining the measurement of paraprotein with imaging tests that help to promptly define response or failure to the treatment.
Aims: The primary endpoint was the correlation of the biochemical response with the FDG PET/CT in a second evaluation after first line treatment. The secondary endpoint was the correlation between MRD and with second FDF PET/CT.
Methods: We included in this retrospective and observational study at Universitary Hospital of Vall d' Hebron, all patients with newly MM and PET/CT before to start a first line treatment and a second PET/CT when completing treatment. PET/CT were analyzed by the department of Nuclear Medicine with experience to grade the lesions in MM, were evaluated and categorized into positive or negative according to the criteria proposed by Zamagni, *et al.* The biochemical response was defined according to the standard IMWG response criteria.
Results: Eighteen patients (8 males and 10 females) with untreated MM entered, seven patients were classified with ISS III, fifteen had a good performance status, none presented renal lesion, only 16% had hypercalcemia and 66% showed immunoparesis. Ten patients were IgG isotype, six were classified as light chains myeloma and two patients were oligosecretors. Seventeen patients had bone marrow infiltration with a median of 42% plasmatic cells. Two patients had a extramedullary plasmocytoma and nine had an anormal ratio of light chains. Seventeen patients were treated with bortezomib-based regimens, (median 5.5 cycles) included VTD, MPV, VLD and VD. After treatment fourteen patients achieved completed response, two partial response and two had progressive disease. PET/CT was positive in all patients pretreatment, 15 focal lesions, 2 diffuse bone marrow involvement plus focal lesions and 1 involvement of bone marrow alone. Twelve patients had more than 3 focal lesions and two had extramedullary disease. At the end of first line treatment, PET/CT was negative in eight patients (44%) and fourteen had complete biochemical response (78%). 62% of the patients with negative PET/CT showed negative flow minimal residual disease (MRD) and biochemical complete response . Two patients had PET/CT with progression disease and corresponded to a biochemical progression.
Summary/Conclusions: The correlation between PET/CT and biochemical response obtained after treatment was positive in patients with complete response. We found discordant data in two patients with oligosecretory myeloma. No correlation was shown between PET/CT and flow MRD.
Are necessary more long term studies that include greater number of patients to confirm that the PET/CT negative is an image technique that could be a tool to follow up patients after the first line treatment added to the evaluation of the biochemical response.

PB2016

MULTIPLE MYELOMA IN BORNEO SARAWAK: A DEVELOPING WORLD'S EXPERIENCE

T.S. Leong[1,*], L.P. Chew[1]
[1]Hematology Unit, Medical Department, Sarawak General Hospital, Kuching, Malaysia

Background: Sarawak, is the largest state of Malaysia situated on the island of Borneo. Sarawak General Hospital is the tertiary referral center of Sarawak (serving a population about 1 million people). It is 980 km away from its main hematology/transplant referral center in Kuala Lumpur, Malaysia, which is accessible only by airplane. Hence, treatment of patients with multiple myeloma in this part of the state is a big challenge due to its geographical constraint.
Aims: To identify demographics and clinical characteristics of patients with multiple myeloma; To establish treatment and outcome of patients with multiple myeloma.
Methods: This is a retrospective study examining basic characteristics and clinical outcomes of patients diagnosed with multiple myeloma between 2010 and 2016 in Sarawak General Hospital. Patients' case notes were traced and the relevant information was entered into a pre-designed data collection form. Data was analysed and interpreted via IBM SPSS Statistics version 24.0.
Results: There were a total of 63 patients with the male to female ratio of 3:2. The median age for patient was 61 years old (range 31 to 86 years old). Majority of them are local natives of Iban or Bidayuh descendants (n=32, 50.8%) followed by Chinese (n=20, 31.7%) and Malays (n=11, 17.5%). Most common type of multiple myeloma is of IgG variant (n=27, 42.9%). The most common myeloma related organ or tissue impairment (ROTI) are anaemia (n=54, 85.7%) followed by bone lesion (n=48, 77.8%), renal impairment (n=27, 42.9%) and hypercalcaemia (n= 18, 28.6%). More than half presented late with Durie Salmon stage III disease (n=34, 54%). Majority of patients were treated with dexamethasone/thalidomide (n=25, 39.7%). Sixteen patients (25%) received bortezomib based treatment. Three patients (n=3, 4.8%) undergone bone marrow transplant. Thirty five patients died (n=35, 55.6%). Median survival time was 21 months (95% CI: 16,26). One year, two years and five years survival rate was 67.4%, 43.6%, 31.6%. Patients who were 60 years old and above have lower median overall survival (20 months) compare to patients who were 60 years and below (36 months) even though they are not statistically significant (p=0.565).
Summary/Conclusions: Baseline characteristics of patients with multiple myeloma in Borneo Sarawak are similar to the rest of Asia. However, our median overall survival was comparatively lower to our counterparts. Limitation wise, due to logistic and economic reasons, we do not have good access to cytogenetic and genetic profiling that enables us to prognosticate patients accordingly.

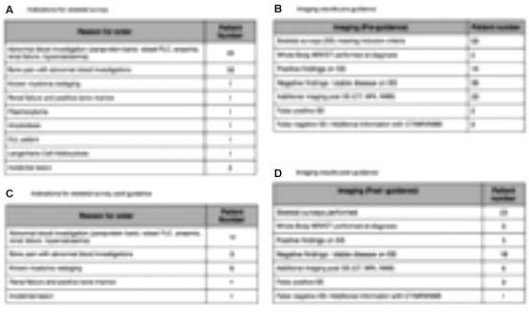
PB2017

A RETROSPECTIVE AND PROSPECTIVE AUDIT OF RADIOLOGICAL INVESTIGATIONS FOR SUSPECTED CASES OF PLASMA CELL DYSCRASIAS/MYELOMA IN THE ALTNAGELVIN AREA HOSPITAL

G. Baker[1,*], N. Cunninghmam[1]
[1]Haematology, Western trust, Londonderry, United Kingdom

Background: The updated NICE guidelines for diagnosis and management of myeloma (2016) suggests whole-body MRI as first-line imaging for people with suspected myeloma and consideration of MRI/CT/PET in newly diagnosed myeloma to assess for bone disease or EM plasmacytoma.
Aims: Our aims were to ascertian; 1) Our current practice regarding radiological investigation for myeloma (2) Whether additional diagnostic information was gained using CT/MRI imaging (3) Since its release, is the trust compliant with the NICE guidance (4) The estimated cost of meeting the current NICE guidance
Methods: This retrospective and prospective audit included all patients having a skeletal survey performed for suspected multiple myeloma within the Altnagelvin Area Hospital (AAH). Retrospectively from 10/2/15 until 9/2/16 data was collected using the advanced search feature of the Sectra IDS7 PACS system. The 'Reason for examination' for each study was then analysed and those ordered for reasons other than suspected myeloma were excluded. Each case was analysed individually and any follow up MRI/CT/NMB imaging performed in the 6 month period following the skeletal survey were included in the data collection. The same information was gathered prospectively from 10/2/16-30/5/16 following the NICE guidance. 54 skeletal surveys where performed for suspected/restaging myeloma pre guidance.
Results: The indications for requesting imaging is shown in Table 1A. No WB MRI/CT was performed in this period. 26% patients had new lytic lesions on skeletal survey. 23 patients had further imaging in the form of MRI or CT following skeletal surveys. All the positive MRI findings offered additional diagnostic information - including examples of missed multiple spinal deposits. The results of imaging are summarised in Table 1B. The false negative rate for skeletal surveys was 39% and the false positive rate was 22%. Following NICE guidance publication 23 patients had skeletal surveys performed for suspicion of myeloma between 10/2/16 and 30/5/16. The indications are summarised in Table 1C. No WB imaging was performed. 5 patients had positive skeletal surveys. 6 patients had subsequent CT/ MRI imaging. A skeletal survey was reported normal with a subsequent MRI showing multiple spinal deposits. The imaging results are summarised in Table 1D.

Table 1.



Summary/Conclusions: The expected cost of implementing WB imaging for 60 patients per year in the AAH is £18,240. In comparison the cost of performing skeletal surveys would be £4200 per annum. NICE guidance 2016 offers an

economic model for imaging with WB MRI. In addition it reviews evidence which links time to diagnosis to survival and myeloma related complications. The NICE guidance offers clear evidence that WB-MRI should be the investigation modality of choice for suspected myelomatous disease. It offers a diagnostic and cost-effective strategy that will ensure health improvements for myeloma patients. This audit offers further evidence of the diagnostic accuracy of MRI imaging. At present failure to comply with NICE guidance will lead to delayed diagnosis of myeloma in certain patients and potential patient harm. Therefore I offer a business and health improvement case for the Western Trust to instigate WB-MRI imaging for all suspected myelomatous bony disease.

PB2018

TONI DEBRE FANCONI SYNDROME DURING MYELOMA, ABOUT 8 CASES

R. Cherif[1,*], B. Salah Eddine[1]
[1]Hematology, Central Hospital Mohammed Seghir Nekkache , Algiers, Algeria, Algiers, Algeria

Background: The cast nephropathy with cylinders is the most frequent renal complication of the myeloma, which results from a catabolism of the light chains by the tubular cells and can lead a tubular chronic suffering showing itself by a syndrome of acquired Toni-Debré-Fanconi marked by a glycosuria, a phosphaturia, an aminoaciduria, a sometimes severe and sometimes revealing hypokalemia.
Aims: We reporting some observations informed by Multiple Myeloma complicated with a Fanconi syndrome.
Methods: From January 2000 till December 2010: 78 cases of Multiple Myeloma were brought together, whose circumstance of discovery 22 cases with renal failure, it's was a evolutes complications in 12 cases; and in 10 cases it's discovered at diagnosis. The renal achievement is dominated by Tubule disease in 11 cases, Randall syndrome 8 cases, and Nephrotic syndrome in 3 cases. The tubule disease of Fanconi is suspected at only 8 patients: in front of the presence of a renal glycosuria (without associated diabetes) and a frank proteinuria in the majority of the cases, with a hypophosphatemia and a fickle hypokalemia.
Results: The clinico-epidemiological and immuno-biological characters of these 8 patients are the following ones: - The median age is of 64 years (39-76), sex ratio=3. The osseous pains and the muscular cramps dominate the clinical presentation with constant diffuse demineralization in the radiology. - The patients were classified (according to the Salmon-Durie classification): IIIB (3 cases) and IIB (5 cases). ISS 3 in majority of the cases. - The monoclonal immunoglobulin observed: IgG kappa: 4cases, IgA kappa: 2cases, light chain kappa: 2cases. With a Bence Jones proteinuria isotype kappa and a glycosuria in the majority of the cases. - The gravity of the renal faillure, based on the clearance of the creatinine: with an average clearance of 16,19 ml/min (4-37): several in 5cases, terminal in 3cases. - We note more of hypocalcaemia while the hypercalcaemia is noted in a single case, the hypophosphatemia is found in half of the cases. The therapeutics is double: - Symptomatic: alkaline hydration, correction of the metabolic disorders and sometimes the renal extra purge (indicated in 3cases). - Specific: chemotherapies VAD 7cases, a patient died by cardio-vascular complication. Under treatment the recovery of the renal function is obtained in 3 cases, to the rests of the patients persists a stable renal failure.
Summary/Conclusions: The Syndrome of Fanconi is a frequent and often formidable complication during Myeloma, observed to 30-40% of the patients in an autopsique series. It is necessary to think to it in front of any renal achievement in myeloma of kappa light chain with renal glycosuria, a generalized amino-aciduria and a hypophosphatemia resulting respectively from a defect of the transport of the glucose, from amino acids and from phosphates by the renal proximal tubule. To improve the osseous and renal appearances, it is necessary to realize a calcic supplementation, phosphorous and by the vitamin D active, as well as the correction of the acidose and a specific treatment reducing the excretion renal of the light chains.

PB2019

DEPP RESPONCES WITH CARLFIZOMIB-LENALIDOMIDE-DEXAMETHASONE IN RELAPSED/REFRATORY MULTIPLE MYELOMA PATIENTS: A REAL LIFE EXPERIENCE

V. Federico[1], B. Rossini[1], D. Carlino[1], A. Mele[1], P. Curci[2], A. Giordano[2], S. Citiso[1], G. Specchia[2], V. Pavone[1,*]
[1]Haematology and TMO, Hospital Card. G. Panico, Tricase (LE), [2]Haematology and TMO, Policlinico di Bari, Bari, Italy

Background: Carfilzomib is a new proteasome inibitor with in contrast to the reversible binding of bortezomib, binds irreversibly and selectively to its target: the chymotrypsin-like activity of the 20S proteasome. The phase IB/II PX-171-006 study was the first study in which carfilzomib was combined with lenalidomide and dexamethasone. In the phase I dose-escalation part the maximum planned dose was established as well tolerated and in the phase II part the study focused the efficacy and toxicity in the subgroup treated with maximum planned dose. The ASPIRE trial showed superior response rates and progression free survival for carfilzomib-lenalidomide-dexamethasone compared with lenalidomide-dexamethasone in relapsed/refractory Multiple Myeloma patients.
Aims: The aims is explorer the efficacy and tolerability of carfilzomib-lenalidomide-dexamethasone in relapsed/refractory Multiple Myeloma patients in real life.
Methods: All patients received carlfilzomib 20/27 mg/m2 days 1,2,8,9,15 and 16; lenalidomide 25 mg days 1-21 and daxamethasone 20 mg days 1,2,8,9,15,16, 22 and 23, according to post approval access protocol. After 2, 4, 6 and 8 cycles the responses, disease progression and toxicity were assessed using the International Myeloma Working Group Uniform Response Criteria and WHO score respectively.
Results: From January 2016 to February 2017 in hematology "Cardinale G.Panico Hospital" and "Bari Policlinico", treated 15 relapsed/refractory Multiple Myeloma patients with carfilzomib-lenalidomiode-dexamethasone. Six patients male (40%), 9 female (90%), mean of age 62 years (range 38-79); 10 (66%) and 5 (34%) relapsed/refractory multiple myeloma respectively. Median time from diagnosis to carfilzomib-lenalidomiode-dexamethasone was 46 months (range 12-92); median of prior therapy was 3 (range 1-6); 9 (60%) received autologous transplantation while 1 (6%) allogeneic; 11 (73%) prior therapy with lenalidomide; 15 (100%) prior therapy with borthezomib; 2 (14%) prior therapy with pomalidomide (Table 1). Eleven (73%) patients achieved after 2 cycles a response rate ≥PR, of these 3 VGPR. After 4 cycles, 5 (33%) and 1 (7%) have obtained at least a VGPR and CR respectively (Figure 1). Three patients were not evaluated for treatment discontinuation because of rapid progression disease and died during first cycle with a median of 5 prior lines therapy. Most grade 3-4 adverse events were haematological and well manageable, 10 (80%) trombocitopenia and 5 (35%) neutropenia grado 3-4. Dyspnea, fatigue and pyrexia were higher but were mostly grades 1 and 2. Only 2 patients developed respiratory failure and pneumonia while cardiac failure, ischemic heart disease and hypertension not were detected.

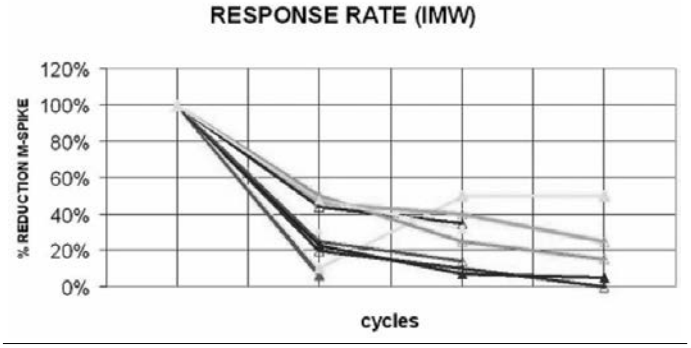

Figure 1.

Summary/Conclusions: Carfilzomib-lenalidomide-dexamethasone is a powerful and efficacy association in relapsed/refractory Multiple Myeloma patients, which allows the achievement of deep responses from the first cycle of therapy. Non haematological adverse events of grade 3 or higher were reported in only 2 patients.

PB2020

CARFILZOMIB-LENALIDOMIDE-DEXAMETHASONE IN THE MANAGEMENT OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A REAL-LIFE EXPERIENCE

C. Cerchione[1,*], K. Ferrara[1], I. Peluso[1], D. Nappi[1], M. Di Perna[1], I. Zacheo[1], A. E. Pareto[1], F. Pane[1], L. Catalano[1]
[1]Hematology, Ematologia e trapianto/au federico ii, Napoli, Italy

Background: Carfilzomib is an epoxyketone proteasome inhibitor of second generation, proved to be effective in relapsed and refractory Multiple Myeloma (rrMM).
Aims: In this retrospective observational trial, it has been evaluated efficacy and tolerance of Carfilzomib, in combination with lenalidomide-dexamethasone (KRD) as salvage regimen in patients with relapsed and refractory MM (rrMM), whose prognosis is particularly severe.
Methods: 21 patients (12 M/9 F, Table 1), with rrMM, median age at diagnosis 62 years (r. 47-75), median age at start of treatment 65 years (r. 53-81) treated with several lines of treatments (median 3, r. 2-10), included 2 patients refractory to Bortezomib, underwent to KRD regimen (ASPIRE trial schedule: Carfilzomib starting dose 20 mg/sqm on days 1,2 of cycle 1, target dose 27 mg/sqm thereafter; Lenalidomide 25 mg on days 1 through 21; Dexamethasone 40 mg on days 1,8,15 and 22, every 28 days) for a median treatment cycles of 2 (r 1-8). ISS was equally distributed, and cytogenetic was evaluable in 8 patients, and in particular one del13q14 1qgain, one del 13q14 and one t(11;14). 86% of patients had previously been treated with schedule containing bortezomib and IMIDs, and 33% had also received radiotherapy. 57% of them had undergone at least to a single auSCT.
Results: Carfilzomib was well tolerated, with grade 2 anemia in 28% of patients, without necessity of blood transfusions; 5% grade 1 and 9.5% grade 3 neutropenia (no ospedalization was required, no septic shocks were observed); 33% grade 2, 19% grade 3 and 5% grade 4 thrombocytopenia, without hemorrhagic events and necessity of transufsions. Concerning severe extrahematologic toxicity, it was observed grade 1 pneumonia in 47% of patients, treated by common antibiotic drugs; grade 2 Hypertension in 24% of patients; grade 3 arrhythmias in 5% of patients; grade 2 dyspnea in 5% of patients; grade 1 fatigue in 9.5% of patients. According to IMWG criteria, after a median follow-up of 3 months (r.1-13), ORR was 66,7% (14/21 : 8 VGPR, 6 PR) with 3 progressive diseases and 2 patients in stable disease, which can be considered as an impressive result in this subset of rrMM patients. In particular, for 1 patient, KRD was, after having achieved at least a PR, a bridge to second auSCT. Median time to response was 2 months (r.1-4), median OS from diagnosis was 47 months (9-170 range), median OS from start of Carfilzomib was 3 months (range 1-13).

IMWG ´14 DIAGNOSTIC CRITERIA TO INITIATE TREATMENT IN NEW DIAGNOSED MULTIPLE MYELOMA: REAL-WORLD STADISTICS

P. Gonzalez[1,*], B. Ballina[1], S. Cerdá[1], M. Fuertes[1], L. Villalobos[1], V. Martínez-Robles[1], J.A. Rodríguez-García[1], F. Escalante[1]
[1]Hematología, Complejo Asistencial Universitario de León, LEON, Spain

Background: Diagnostic criteria for Symptomatic Multiple Myeloma (MM) Published in 2003 by the International Myeloma Working Group(IMWG'03) established for the presence of a bone Marrow infiltration by plasma cells (BMPC) in any percentage And / or the presence of a monoclonal component of any amount Along with the presence of signs or symptoms of organ damage (CRAB) attributable to the proliferation of plasma cells. These criteria have not changed in the last decade until the Recent revision of diagnostic criteria and treatment that IMWG Published by the end of 2014, which proposes an initial Pathologic condition (>10% BMPC or demonstration of a Plasmacytoma) as a preliminary condition before starting treatment. Due to "CRAB redefined" and / or the presence of markers of Rapid progression to "classical-symptomatic" MM criteria.
Aims: There are few information about real-life statistics in NDMM according to new criteria to initiate treatment.
This 2year analysis shows a percentage of patients (22%) who have initiated new treatments superior to those described in the literature
Methods: We have performed a retrospective analysis with all new MM cases diagnosed from Dec-2014 (after new criteria were published) to Feb-2017 (28 months). 55 patients were diagnosed of MM. 26 were male and 29 female. The median age at diagnosis was 74 years (52-87), 11 were under 65 (U65) and 44 were over 65 (O65).
Results: 3 were diagnosed after biopsy of plasmacytomas. None of them have Bone Marrow (BM) infiltration but with criteria of MM after PET-CT multitopic involvement. 7 of these NDMM were smoldering MM (sMM). All of then completed initial staging with more sensitive imaging tests than conventional radiology (MRI and / or PET-CT) 2 of these sMM were under 65 years old and were included in a clinical trial. The other 5 were older than 65 and after a median of 16 months of follow-up did not meet criteria in initiate treatment. Of the 41 patients who started treatment, 10 of them were new criteria, the rest met criteria for classic organic disease (CRAB) Figure 1. 6 patients were diagnosed after performance of PET-CT (3 of them after plasmacytoma biopsy; initial diagnosis: solitary plasmacytoma), 1 after PET-CT negative but MRI positive, 2 with FLC ratio criterium and the last one with BM Plasmatic Cell (BMPC) >60%, MRI image and FLC criteria. Although these data are quite different from those reported previously, accurate diagnosis in initial stages may increment the proportion of real-active MM. We don´t observe increments in incidence rate in these period *vs* pre´2014 (reported to 22nd EHA abstract). We observe that the early mortality is decreasing in the last 5 years (from 2013). The effect of early diagnostic may contirbute to get these improvement of survival.

	1	2	3	4	5	6	7	8	9	10
CRAB	-	-	-	-	-	-	-	-	-	-
FLC	-	-	-	-	-	-	+	+	+	-
BMPC	-	-	-	-	-	-	-	-	+	-
PET-CT/MRI	+	+	+	+	+	+	-	-	+	+

Characteristics of the 10 patients who got treatment due to new criteria

Figure 1.

Summary/Conclusions: One of the hypotheses for introducing new criteria for initiating treatment was that the initiation of adequate and early treatment may improve the prognosis of patients with symptomatic NDMM. In an aging population such as the one we present, we believe that these new criteria to initiate treatment can improve the medium- and long-term prognosis of this group of people with few chance to start intensive or a lot of lines of treatment because of increasingly comorbidities by age. Further follow-up and evaluation of survival comparing the "classical" group *vs* new-criteria group are guaranteed to assess if these early treatment will improve survival.

PB2022

POMALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE: A CHANCE FOR RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA. A REVIEW OF A CASE SERIES DIAGNOSED IN A SINGLE CENTER

A. Gil Pérez[1,*], D. de Miguel [1], D. Subirá[1], H. Guillén[1], A. Vázquez[1], M. Díaz[1], N. Golbano[1], D. Morales[1], S. Herrero[1], J. Arbeteta[1], B. Pinedo[1]
[1]Hospital General Universitario de Guadalajara, Guadalajara, Spain

Background: The treatment of patients with multiple myeloma (MM) has dramatically changed over the past decade due in part to the development of new agents and myeloma-specific targets. Nowadays, new effective treatments exist for patients with RRMM not responding to bortezomib and lenalidomide. Pomalidomide alone has shown limited efficacy in patients with RRMM, but synergistic effects have been noted when combined with dexamethasone.
Aims: To show our experience with the use of 28-day cycles of pomalidomide (4 mg/day on days 1–21, orally) plus low-dose dexamethasone (40 mg/day weekly, orally) (Pom/dex) in RRMM.
Methods: This is a retrospective study performed between May 2014 and January 2017 in the Hospital of Guadalajara (Spain). Eight patients (3M, 5F), with a median age of 67 years (range, 40-81), diagnosed with MM were included. Four were classified as high-risk myeloma (Patients 1-4). Patient 1 (P1) had plasma cell leukemia and received Pom/dex plus bortezomib; Patient 2 (P2) presented complex karyotype and received Pom/dex after three previous regimens and an autologous transplantation; Patient 3 and Patient 4 (P3 and P4) had extramedullary plasmacytoma and received Pom/dex±local radiotherapy. The eight patients of this study had failed to bortezomib and lenalidomide-based therapy, and received Pom/dex until disease progression or unacceptable toxicity. Pom/dex was associated with ciclophosphamide in two patients, and with bortezomib in another two patients. The primary endpoint was progression-free survival (PFS).
Results: The median number of prior regimens was 2 (range, 1-4) and five of eight patients (62.5%) had previously received autologous transplantation. Median time from diagnosis to Pom/dex was 51.5 months (range, 28-155). Patients received a median of 6 cycles of Pom/dex (range, 2-16). In the whole series, the median follow-up was 60.5 months (IQR: 56.0-80.25), and median PFS was 11 months; 75% of patients had not progressed after 5 months, and 50% of patients after 11 months. The overall response rate was 87.5% (only one patient discontinued therapy for non-response). In standard-risk MM patients, median follow-up was 61 months (IQR: 46.25-140.25), and median PFS was 13 months; 75% of patients had not progressed after 2 months, and 50% of patients after 13 months. Regarding the high-risk group of patients, P1 achieved complete response after 6 cycles of Pom/dex+bortezomib; P2 achieved PFS of 11 months; P3 achieved plasmacytoma resolution after 6 cycles of Pom/dex plus local radiotherapy; P4 abandoned Pom/dex after 3 cycles because of severe neutropenia and sepsis. In this group median follow-up was 60.5 months (IQR: 56.3-79.8), and median PFS was 6 months; 75% of patients had not progressed after 5 months, 50% of patients after 6 months, and 25% of patients after 11 months. Regarding adverse events, they were present in two patients: one had neutropenia, and the second one pneumonia plus pulmonary venous thromboembolism. Both of them died (Figure 1).

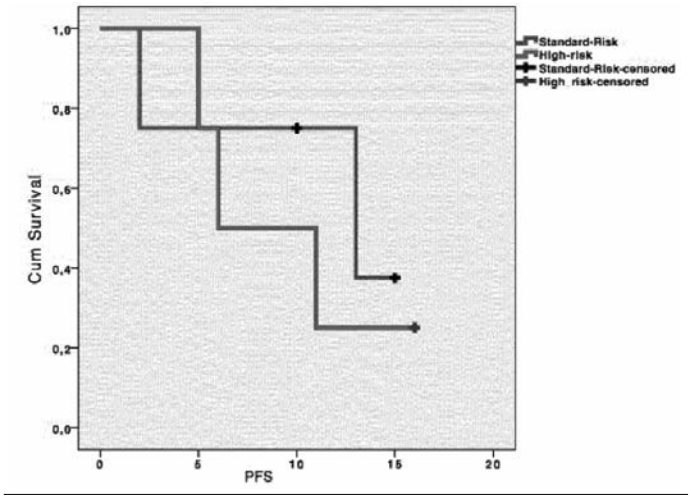

Figure 1.

Summary/Conclusions: In our experience, Pom/dex regimen has prolonged PFS of patients with RRMM, with an improvement of health-related quality of life. This regimen has been even valuable in high-risk patients who received Pom/dex after ≥2 treatment regimens. Pomalidomide plus low-dose dexamethasone, an oral regimen, could be considered a new treatment option as a standard of care for patients with RRMM who have poor prognosis and a high need for effective treatments.

ROUTINE SCREENING FOR KIT M541L IS NOT WARRANTED IN THE DIAGNOSTIC WORK UP OF PATIENTS WITH HYPEREOSINOPHILIA

N. Cross[1,*], Y. Hoade[1], G. Metzgeroth[2], J. Schwaab[2], A. Reiter[2]
[1]University of Southampton, Southampton, United Kingdom, [2]Universitätsmedizin Mannheim, Mannheim, Germany

Background: The role of the KIT M541L variant in patients with hypereosinophilia (HE) is controversial. On the one hand, this variant is a recognised inherited single nucleotide polymorphism (c.1621 A>C; rs3822214) with a minor allele frequency of 0.08 in the ExAC database and classified as benign/likely benign on ClinVar. On the other hand, it has been suggested that KIT M541L increases the sensitivity of the KIT receptor to stem cell factor (Foster R *et al.*, Br J Dermatol. 2008;159:1160-9) and may be somatically acquired in imatinib responsive CEL-NOS patients negative for PDGFRα/β abnormalities (Iurlo A *et al.*, Oncotarget. 2014;5:4665-70). Consequently it has been suggested that HES patients should be screened for KIT M541L, as positive cases may benefit from imatinib treatment.
Aims: We aimed to (i) compare the KIT M541L allele frequency between patients referred for investigation of HE and normal healthy controls (ii) investigate the variant allele frequency (vaf) to determine if KIT M541L mutations may be acquired somatically and (iii) investigate the KIT M451L status in cases negative for PDGFRα/β abnormalities who responded to imatinib.
Methods: We screened healthy controls (n=214) and patients referred for investigation of *FIP1L1-PDGFRA* negative HE (n=220) for KIT M541L using an amplification refractory mutation system (ARMS) PCR designed to amplify allele specific products of different sizes, and able to detect KIT M541L down to 5% vaf. Fishers exact two tailed test was used to compare the allele frequency between the control and HE groups. Digital droplet PCR (ddPCR) was used for patients heterozygous for KIT M541L by the ARMS assay to determine whether the KIT M541L mutation burden was close to 50% (consistent with a constitutional polymorphism) or <50% (suggestive of a somatic mutation). We also studied pre-treatment DNA from 3 patients with hypereosinophilic syndrome who were treated with imatinib (400 mg/day) and showed normalization of eosinophil counts at a median of 0.8 months (0.4-5.0) after treatment for a duration of 13.6 months (range, 3.7-44.8).
Results: Forty two (19%) of HE cases tested positive for KIT M541 compared to 38 (18%) of healthy controls. The KIT M541L allele frequency was no different between cases and controls (0.095 *versus* 0.098; P=0.91). Of the 42 KIT M541L heterozygous HE cases, 40 had sufficient DNA for analysis by ddPCR. The mean allele burden was 50.4% (range 48.3%>56.0%), consistent with all instances being constitutional. None of the three imatinib responders tested positive for KIT M541L prior to treatment.
Summary/Conclusions: Whilst we cannot exclude the possibility that KIT M541L may be acquired somatically in very rare cases, we conclude that there is no clinical value in screening for this variant on a routine basis for patients with HE or HES.

MUTATIONS OF THE JAK2 GENE AND CYTOGENETIC ABNORMALITIES ARE PREDICTIVE OF PROGRESSION TO HEMATOLOGICAL NEOPLASMS IN PATIENTS WITH IDIOPATHIC LEUKOCYTOSIS

N. Mori[1,2,*], K. Yoshinaga[3], M. Ohwashi-Miyazaki[3], M. Shiseki[3], H. Sakura[4], J. Tanaka[3]
[1]Hematology, Tokyo Women's Medical University, [2]Internal Medicine, Tokyo Women's Medical University Medical Center East, [3]Hematology, Tokyo Women's Medical University, [4]Internal Medicine, Tokyo Women's Medical University Medical Center East, Tokyo, Japan

Background: Idiopathic leukocytosis and erythrocytosis are hematological disorders without specific causes. Frequent V617F mutations on the *JAK2* gene have been reported in patients with polycythemia vera (PV), essential thrombocythemia, and primary myelofibrosis. We also found *JAK2* V617F mutations in one of 11 patients with idiopathic erythrocytosis. Mutations of the *CSF3R, SETBP1,* and *ETNK1* genes have been found in chronic neutrophilic leukemia and atypical chronic myeloid leukemia (CML). Furthermore an autosomal mutation was found in the *CSF3R* gene in a family with chronic neutrophilia. However, little is known about mutations associated with idiopathic leukocytosis.
Aims: We previously analyzed the *JAK2, CSF3R, CALR*, *SETBP1,* and *ETNK1* genes in 10 patients with idiopathic leukocytosis (EHA20). To elucidate the relevance of genetic alterations, we extended the analysis with 17 genes known to be involved in hematological neoplasms in 16 patients with idiopathic leukocytosis.
Methods: Leukocytosis is defined as a total white blood cell count more than two standard deviations above the mean, or a value greater than 11,000/μL. Those patients who satisfied the following criteria were included in the study: leukocytosis (predominantly neutrophils); the absence of apparent causes of leukocytosis; and documentation of the leukocytosis over a prolonged period

of time. The period of observation was 1 year or longer in most patients. Sixteen patients with idiopathic leukocytosis were analyzed in the study. Neutrophils or mononuclear cells were collected after obtaining written informed consent from the 16 patients. Neutrophils from peripheral blood were purified by dextran sedimentation followed by hypotonic lysis and centrifugation with Ficoll-Conray. Mononuclear cells were isolated from bone marrow by Ficoll-Conray gradient centrifugation. Genomic DNA was extracted using the QIAamp DNA blood mini kit (Qiagen, Valencia, CA, USA). Mutations within hot spots of the *CSF3R, JAK2, CALR, SETBP1, ETNK1, CBL, TET2, ASXL1, EZH2, IDH1/IDH2, DNMT3A, U2AF1,* and *CEBPA* genes were analyzed by direct sequencing in both directions using a 3730xL DNA Analyzer (Life technologies, Carlsbad, CA, USA) and/or allele specific polymerase chain reaction analysis. Total RNA extraction and reverse transcriptase polymerase chain reaction (RT-PCR) were performed between the *ETV6* and *ABL1* genes in 10 patients. *BCR/ABL1* gene was analyzed by RT-PCR or fluorescence *in situ* hybridization in 8 patients. The current study was conducted within the guidelines and with the approval of ethical committee.
Results: *JAK2* V617F mutations were found in one of the 16 patients with idiopathic leukocytosis. No mutations were found in the other genes in the 16 idiopathic leukocytosis patients. *ETV6-ABL1* fusion gene was detected in one of the 10 patients. No *BCR/ABL1* fusion gene was detected in the 8 patients. One idiopathic leukocytosis patient with *JAK2* V617F mutation has developed PV. Another patient with sustained leukocytosis for 20 years showed cytogenetic abnormalities during observation and has developed Philadelphia chromosome negative CML (Ph-CML). *ETV6-ABL1* fusion gene was detected in this patient. Another patient with normal karyotype progressed to blast crisis of Ph-CML accompanied by cytogenetic abnormalities. Of the remaining 13 patients with idiopathic leukocytosis, one resolved the disease and twelve had a stable disease.
Summary/Conclusions: Idiopathic leukocytosis comprises heterogeneous conditions. *JAK2* mutations and cytogenetic abnormalities are predictive of progression to hematological neoplasms.

EVALUATION OF EXPRESSION OF MIRNAS ISOLATED MICROVESICLES OF PATIENTS WITH MYELOFIBROSIS ASSOCIATED WITH DISEASE
L. Rodrigues[1], J. Barros[1], A. Nonino[1], C. Mascarenhas[1,*]
[1]Biotecnologia, Universidade Católica De Brasília, Brasília,, Brazil

Background: Myelofibrosis is a hematological disease inserted in the group of myeloproliferative neoplasias. It has as main characteristic fibrosis of the bone marrow, consequence of a variety of histological changes presented in the medullary microenvironment. The development of the disease is related to the clonal expansion of myeloid stem cells, abnormal expression of cytokines, hypercellularity of myeloid lines and also extramedullary hematopoiesis. The pathophysiology of myelofibrosis involves the activation of signal transduction pathways, which may occur due to genetic rearrangements and mutations that alter the structure of protein tyrosine kinases, making hematopoietic progenitor cells independent or hypersensitive to cytokines, generating anomalous cellular behavior. Myelofibrosis is a hematological disease inserted in the group of myeloproliferative neoplasias. It has as main characteristic fibrosis of the bone marrow, consequence of a variety of histological changes presented in the medullary microenvironment. The development of the disease is related to the clonal expansion of myeloid stem cells, abnormal expression of cytokines, hypercellularity of myeloid lines and also extramedullary hematopoiesis. The pathophysiology of myelofibrosis involves the activation of signal transduction pathways, which may occur due to genetic rearrangements and mutations that alter the structure of protein tyrosine kinases, making hematopoietic progenitor cells independent or hypersensitive to cytokines, generating anomalous cellular behavior.
Aims: Recent studies have shown that microvesicles produced by cells of the organism may be associated with the cellular communication process due to their intravesicular content and that miRNAs also found in this content are able to regulate diverse cellular processes. The expression of some microRNAs is associated with hematopoietic processes such as the transformation of myeloid, erythroid and megakaryocytic progenitors. These can regulate the hematopoiesis of normal stem cells and also of compromised progenitors, having an important role in the pathogenesis of some acquired hematological malignancies. The objective of this work is to investigate the presence of specific miRNAs in microvesicles excreted in peripheral blood plasma of patients with myelofibrosis, which may be related to cellular communication.
Methods: Microvesicles were isolated from the plasma by ultracentrifugation method and through molecular biology techniques it was possible to validate their presence. Assays by qPCR were performed to evaluate the presence of specific miRNAs.
Results: We used the miRNAs described in the literature as influential in the process of hematological disorders. They are: mir146b, mir 150, mir 29a and 155. After analysis of miRNA differential expression, miR-29a and miR-155 were less expressed in MF patients compared to healthy donors (P <0.02 and P <0.03), and miR-223 did not Presented a statistically significant difference. Data on miR-29a corroborate in part with the literature, since the data presented here relate to miRNA carried by VEs rather than serum / plasma. However, low levels of miR-29a expression are related to aberrant auto-renewal of hematopoietic progenitor cells, thus indicating that VEs may contribute to this mechanism. As for miR-155, the data obtained do not corroborate with the literature and, possibly, the VEs do not participate in the mechanism of regulation of Megacariopoiese by miR-155. We used the miRNAs described in the literature as influential in the process of hematological disorders. They are: mir146b, mir 150, mir 29a and 155.After analysis of miRNA differential expression, miR-29a and miR-155 were less expressed in MF patients compared to healthy donors (P <0.02 and P <0.03), and miR-223 did not Presented a statistically significant difference. COMPREHENSIVE STUDY OF BCR/ABL GENE EXPRESSION IN PROGRESSION OF "CLASSIC" MYELOPROLIFERATIVE DISORDERS
L. Kesaeva[1,*], A. Misyurin[2], V. Tikhonova[1], Y. Finashutina[2], H. Mkrtchyan[3], V. Misyurin[4], N. Kasatkina[5], A. Krutov[3], I. Soldatova[3], E. Misyurina[3]
[1]N.N.Blokhin Russian Cancer Research Center, [2].N.Blokhin Russian Cancer Research Center, [3]GeneTechnology LLC, Moscow, Russian Federation, [4]Kashirskoe shosse, 24, GeneTechnology LLC, [5]N.N.Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Classic myeloproliferative disorders (MPDs) also known as chronical MPDs, include several clonal hematologic diseases (such as polycythemia vera (PV), essential thrombocythemia (ET), primary myelofibrosis (PMF)), which are negative for t(9;22) translocation, result to BCR/ABL chimeric gene expression . Characterization of JAK2V617F mutation, deletion in 12 exon of JAK2 gene, MPL W515L/K, mutation in calreticulin gene (CALR) contributed a lot to understanding of molecular pathogenesis of MPDs. However, detailed molecular mechanism underlying the progression of MPD remains unclear. Several cases of MPDs with detected BCR/ABL expression were described repeatedly in previons publications. The phenomen of simultaneous coincidence of mentioned molecular markers in each clinical case requires comprehensive study.
Aims: The aim our work was to investigate BCR/ABL expression in therapy resistant MPD patients with disease progression.
Methods: Peripheral blood samples 175 patients with progressive MPD and 67 patients with primary MPD was used as a biological material for experiments. Qualitative and quantitative analysis of BCR/ABL gene (p190, p210, p230) was performed by two-step PCR and real-time PCR. Jak2, Jak2-e12, MPL, CALR mutations were determined by direct sequencing and allele-specific PCR. RAG1 and RAG2 expression was analyzed by real-time PCR.
Results: 175 patients with progressive MPD were analysed: 35(20%)- PV, 38(22%)- ET, 102(58%)-PMF. BCR/ABL gene expression was identified in 47 cases (32,83%). We found 44 cases with BCR/Abl /p210, 3 cases with BCR/Abl/p190, and no cases of BCR/Abl/p230. We have observed hepatomegaly (17/43- 40%) and elevated WBC in BCR/ABL positive cases. JAK2V617F mutation was identified in 139 patients, deletion in 12 exon of JAK2 gene was found in 2 patients. One case with MPL W515L mutation and 11 cases with CALR mutation were identified. Group of primary MPD patients (N= 67)- 26(47%)-PV, 21(38%)-ET, 8(15%)-PMF, contained 55/67(82%) patients with JAK2V617F mutation. Expression of BCR/ABL/p210 was detected only in 2/55(3,6%). We also found that expression levels of key components of V(D)J recombinase RAG1 and RAG2 in granulocytes is higher in Jak 2V617F-positive MPDs patients(46/49- 94% cases) compared to heathy donors (3/42- 7%).
Summary/Conclusions: The normal rearrangement of immunoglobulin receptors in maturing B-lymphocytes depends on JAK-kinases activation. Therefore we suppose that activation of key components of V(D)J recombinase (RAG1/RAG2) could lead to appearance of additional clone with chimeric BCR/ABL due to increased tension of Jak-STAT pathway.. The expression of BCR/ABL gene could be the possible reason for MPD progression and should be considered as an indication for complementary therapy.

IMMUNOHISTOCHEMICAL ANALYSIS OF CALRETICULIN MUTATIONS IN PRIMARY MYELOFIBROSIS (PRMF) PATIENTS: RESULTS OF OUR INSTITUTION IN THE JAK2V617F MUTATED AND JAK2V617F WILD TYPE PRMF PATIENTS
S.U. Bozkurt[1,*], F. Geçgel[2], I. Atagündüz[2], Y. Ağyol[3], K. Türköz[1], T. Tuğlular[2]

[1]Pathology, [2]Hematology, [3]Internal Medicine, Marmara University, Istanbul, Turkey

Background: Myeloproliferative neoplasms (MPNs) are a group of chronic myeloid cancer characterized by overproduction of mature hematopoetic cells. Mutations in one of three genes; Janus kinase 2 (JAK 2), myeloproliferative leukemia protein (MPL) and calreticulin (CALR), have been found in most patients with BCR-Abl negative MPNs. JAK2 mutations are present virtually all cases of Polycythaemia Vera and 50-60% of prMF and Essential Thrombocythemia (ET). Recently, mutations in CALR gene were found in 50-80% of JAK2 and MPL mutation negative ET and prMF patients.
Aims: To evaluate immunohistochemical results of CALR gene mutation in the bone marrow samples of the JAK2V617F mutated and JAK2V617F wild type Primary Myelofibrosis (prMF) patients.
Methods: Material: Bone marrow biopsy samples from 32 patients previously diagnosed as primary myelofibrosis with known JAK V617F mutation status were obtained from archives of Marmara University Pathology Laboratory. Bone marrow samples of two patients were already known as CALR mutated by PCR analysis. Bone marrow samples of three JAK2 wild type and CALR mutated ET, two JAK2 wild type, CALR mutated prMF patients and two CALR wild type ET patients were used as positive and negative control tissues for CALR immunohistochemistry. Immunohistochemistry: 4-µm unstained sections of each bone marrow biopsy specimens were cut onto electrostatically charged glass slides. Immunohistochemistry was performed on an automated immunostainer (Ventana BenchMark Ultra; Ventana Medical Systems, Inc). CALR antibody (clone CAL2, Dianova, Germany) staining used a 1:100 dilution.Any cytoplasmic staining of the cells with CAL2 antibody was considered positive immunostaining.
Results: We studied 32 bone marrow specimens of primary myelofibrosis with 15 (47%) of them having JAK2 V617F mutation and 17(53%) of them lacking JAK2 V617Fmutation. CALR immunoreactivity was seen in 8 (25%) of all pr MF patients. CALR immunoreactivity was seen in 8 (47%) of patients with PMF myelofibrosis who are negative for JAK2V617F mutation. CALR immunoreactivity was not seen in patients with PMF myelofibrosis who are positive for JAK2V617F mutation. CALR immunoreactivity was seen in 3 (100%) of patients with ET and 2 (100%) of patients with known CALR mutation. CALR immunoreactivity was not seen in patients with CALR wild type ET patients. We observed that CAL2 immunostaining was seen mainly in the cytoplasm of the small and large megakaryocytes, and atypical megakaryocytes as found in fibrotic PrMF. Pale immunostaining was seen in myeloid and erytoid cell precursors. This immunostain also stained some small cells appearing as micromegakaryocytes.
Summary/Conclusions: An immunohistochemical stain easily detects the CALR mutation by staining of megakaryocytes in formalin-fixed bone marrow biopsy specimens . This method would be a easy, rapid, and cost effective way to detect CALR mutations in daily routine hematopathology biopsy evaluation of the myeloproliferative patients.

PB2028

THE HIF1A/2A MRNA INDEX HAS A SIMILAR TREND AS THE CHANGES OF EXPRESSION MRNA CALR AND MDR1 GENES IN WHOLE BLOOD SAMPLES OF PATIENTS WITH JAK2 V617F POSITIVE MPN

A. Gorbenko[1], M. Stolyar[1,2,*], M. Mikhalev[1,3], E. Vasiliev[1,4], V. Khorzhevskyi[5], I. Olkhovskiy[1,6]
[1]Department of Health, Krasnoyarsk branch of the Federal State budgetary Institution «Hematology Research Center», [2]Siberian Federal University, [3]Krasnoyarsk city Clinical Hospital № 7, [4]Krasnoyarsk regional hospital, [5]Krasnoyarsk State Regional Bureau of Pathology , [6]Krasnoyarsk Scientific Center SB RAS, Krasnoyarsk, Russian Federation

Background: Various groups have reported that isoforms of hypoxia-inducible transcription factor 1a (HIF-1a) and 2a (HIF-2a) can regulate both overlapping and distinct target genes. HIF-1a and HIF-2a have been shown to play opposite roles in the regulation of macrophage function [Takeda N. e.a., 2010]. HIF-index incorporated as a strong prognostic biomarker of renal cell cancer [Szendrői A. e.a., 2016]. Only HIF1a was known as regulator expression of multidrug resistance gene (MDR1) and response to chemotherapy [Comerford K.M. e.a., 2002]. New data have shown exclusive role of HIF-2α in regulates the proliferation and glucose metabolism in erythroleukemia cells [Xu Q.Q. e.a., 2016]. No any information about relations between index of HIF and mRNA gene expression level MDR1 or CALR in patients with myeloproliferative neoplasms (MPN).
Aims: Investigate the mRNA expression levels of HIF-1a and HIF-2a, MDR1 and CALR genes in whole blood samples from patients with JAK2 V617F positive MPN.
Methods: Real-time PCR was performed to detect of HIF1a, HIF2a, MDR1 and CALR mRNA transcripts levels in white blood cells 14 healthy volunteers (median age 22 years, range 21-58 years, 57% males) and 11 (median age 44 years, range 20-77 years, 45% males) patients with JAK2 V617F-positive MPN, median of allelic burden is 36%, range 9-87%. Venous blood were collected in tube with RNAse inhibitor. Total RNA was isolated using "RIBO-zol-D" (Aplisens) and were transcribed using "Reverta-L" (Aplisens). PCR was optimized for the thermocycler CFX96 (Bio-Rad). The results were calculated utilizing the delta Ct method in the software package of "R". The threshold cycles (Ct) genes and housekeeping genes (TBP, GUS, ABL) determined using Cy0 method. The results was normalization with this reference genes. Mann-Whitney U test was used to evaluate significant difference between the groups, the degree of correlation (r) was assessed using Spearman test.
Results: We observed a lower mRNA expression MDR1 and CALR in whole blood samples of patients with MPN compared with a group of healthy volunteers (Figure 1). The expression level of mRNA HIF2a not changed and for HIF1a it should be noted a tendency for statistical significance. It found no correlation between allelic burden and mRNA expression level. Index HIF 1a/2a more clearly showed a correlation with the fall of MDR1 and CALR mRNAs (r= -0.64 in control and r= -0.7 in MPN group, p<0.05). CALR gene unlike MDR1 gene is not known among the target HIF regulation, but their unidirectional change indicates the possible metabolic links.

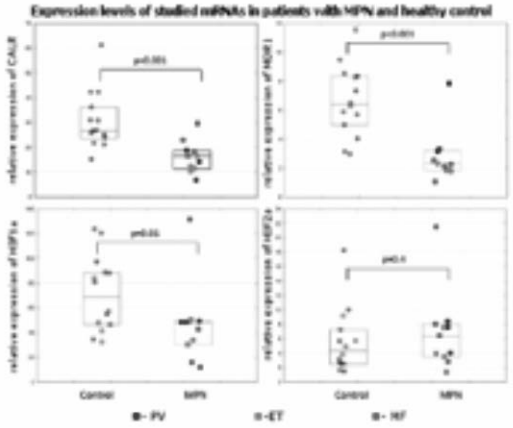

Figure 1.

Summary/Conclusions: We assume that the studied gene expression changes reflect the metabolic processes in the bone marrow progenitor cells. Probably JAK2 V617F mutation leads to more favorable microenvironment and reduced willingness to autophagy, causing the index shift HIF1a/2a. We found reduced of mRNA CALR expression in blood cells at MPN and this fact require further investigation.

PB2029

CD177 EXPRESSION IN PERIPHERAL BLOOD NEUTROPHILS IN HEALTH AND DISEASE STATES

A. Arafat[1,*], S. Rizk[1], R. Samy[1], N. Al-Husseiny[2], R. El-Hawary[1]
[1]Clinical and chemical pathology, [2]Internal medicine, Cairo university, Cairo, Egypt

Background: Objective and specific assays are required in the identification of both chronic myeloproliferative disorders and myelodysplastic syndromes.
Aims: Exploration of the possibility of using the CD177 expression in the peripheral blood neutrophils for the diagnosis of either entity.
Methods: The 213 subjects were organized into 4 main groups; benign neutrophil leukocytosis group, secondary erythrocytosis group and clonal myeloid neoplasms group together with a haematologically normal group as controls. All cases were subjected to clinical assessment as well as the flow cytometry determination of the percentage (%) and mean fluorescent intensity (MFI) of peripheral blood neutrophils expressing CD177.
Results: Skewed high peripheral blood neutrophil CD177 MFI was significantly associated with Philadelphia-negative cMPDs patients (2.9-37.4; median 14.1) compared to controls (0.8-20.5; median 8.8). The MDS patients did not show a significant difference in either CD177% or MFI compared to the controls. Polycythemia Vera (PV) patients had similar results of CD177 expression (% and MFI) compared to Essential Thrombocytosis (ET) patients. However, they had higher CD177 MFI levels compared to the secondary erythrocytosis patients and controls (4.8-37.4; median 16.5, 1.58-25.7; median 5.81, 0.85-20.5; median 8.8 respectively). CD177 MFI showed statistically significant higher values in ET patients compared to the haematologically normal control group (2.9-34.5; median 13.4 *versus* 0.85-20.5; median 8.8 respectively). No correlation between CD177 expression and JAK2 V617F allele burden could be detected in either PV or ET patients. With a 20 p.d.u cutoff, the specificity of neutrophil CD177 MFI in Philadelphia-negative cMPDs patients' diagnosis and differentiation of PV from secondary erythrocytosis was 93% and 85% respectively. The CD177% had a low accuracy of in the diagnosis of MDS patients. The CD177 patterns observed were one positive peak and bimodal pattern (Figure1).
Summary/Conclusions: The CD177 expression is highly associated with Philadelphia-negative cMPDs. It could reliably represent a useful potential marker in detecting those disorders and differentiating them from reactive cases.

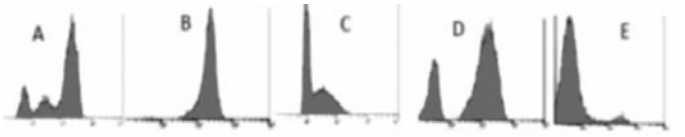

Figure 1. Patterns of peripheral blood neutrophil CD177+ve cells expression observed in flow cytometry. A) Bimodal pattern. B, C, D, E) CD177 single positive peak varieties.

PB2030

DETECTION OF THE MUTATIONS IN GENES JAK2 AND MPL IN THE DIAGNOSIS OF CHRONIC MYELOPROLIFERATIVE DISORDERS

K. Boboev[1,*], K. Karimov[1], A. Mohammad[1]
[1]institute of hemotology and blood transfuzion, tashkent, Uzbekistan

Background: Chronic myeloproliferative diseases is a group of clonal Ph-negative hematological diseases, which include erythremia (polycythemia Vera, PI), chronic megakaryocytic leukemia (essential thrombocythemia, ET) and subleukemicmyelosis (primary myelofibrosis, PMF, chronic idiopathic myelofibrosis). The origin of these diseases is linked to transformation of hematopoietic stem cells, the result is the excessive production of mature cells of erythroid, granulocytic and megakaryocyte shoots with relatively long course of the disease. The frequency of occurrence of mutation V617F of gene JAK2 exon 12 and MPL gene varies in different literature.
Aims: Determination of the frequency of occurrence of mutations in genes JAK2 and MPL and identifying the importance of the verification of these diseases.
Methods: The study included 350 patients with chronic myeloproliferative diseases — with polycythemia Vera 150 patients, with essential thrombocythemia 78, with chronic idiopathic myelofibrosis 55 and 67 patients were examined with the purpose of differential diagnosis with Ph(-) Chronic myeloproliferative diseases. The age of patients ranged from 20 to 70 years, median age was 54 years. Isolation DNA of patients was carried out using a set of reagents "AmpliPrep RIBO-prep" (OOO Interlabservice, Russia). The concentration and purity of isolated DNA was determined by Nano Drop 2000 instrument (USA). Detection of gene mutation JAK2V617F and MPL gene was carried out by standard polymerase chain reaction on a thermal cycler 2720 "Applied Biosystems" (USA), using a set of "Litech" (Moscow).
Results: The result of the research showed that the incidence of the V617F mutation in JAK2 was varying in patients depending on the type of disease. In polycythemia Vera the mutation V617F in the JAK2 gene was identified in 147 patients of 150 (98,3%), with essential thrombocythemia in 42 patients of the 78 (54,2%), with chronic idiopathic myelofibrosis in 27 patients of 55 (49.1%). In 67 patients with no hematological profile, wich examined with the purpose of differential diagnosis with Ph(-) chronic myeloproliferative diseases, V617F in JAK2 was detected in 6 (8,6%), which allowed to confirm Ph(-) Chronic myeloproliferative diseases. A mutation in exon 12 of the JAK2 gene was detected in 2 of 33 (2,9%) of those surveyed V617FJAK2-negative patients exclusively diagnosed with polycythemia Vera. The MPL W515L mutation gene was detected in polycythemia Vera and chronic idiopathic myelofibrosis 2.2% (1 of 41) and 2% (1 of 52) of patients.
Summary/Conclusions: Thus established, our data confirm that mutations in the genes JAK2 and MPL are highly specific diagnostic markers in patients with Ph-negative chronic myeloproliferative diseases.

PB2031

ASSOCIATION OF MYELOPROLIFERATIVE NEOPLASM AND LYMPHOPROLIFERATIVE DISORDER IN 3 PATIENTS

B. Foucher[1,*], M. Dudez[2], M. Daniel[2], S. Girard[2], C. Froelich[2], F. Mestrallet[2], I. Tigaud[3], S. Hayette[4], A. Belhabri[5], M.P. Pages[2], L. Vila[6,7]
[1]Laboratoire, Hopital d'instruction des armées Desgenettes, [2]Laboratoire, Groupement Hospitalier EST, [3]laboratoire, Groupement hospitalier Sud, [4]department of cytogenetics and molecular biology, Groupement Hospitalier EST, [5]department of oncology and hematology, Centre Leon Berard, [6]laboratory, Groupement Hospitalier EST, [7]laboratoire, Centre Léon Bérard, Lyon, France

Background: Lymphoproliferative disorders (LPD) and myeloproliferative neoplasms (MPN) are two very different sets of hematological pathologies. However, several studies have shown that the risk for LPD onset in patients with MPN is higher than in the general population (1)(2). No single LPD seems to be more at cause and all MPN are likely to present the onset of an associated LPD.
Aims: We present 3 cases diagnosed in the Department of Hematology, « Groupement Hospitalier Est », Lyon, France, of patients bearing an association of MPN and LPD: an essential thrombocythemia (ET) with myeloma, ET with marginal zone lymphoma and a chronic myeloid leukemia with chronic lymphoid leukemia.
Methods: Diagnosis have been made thanks to cytology of peripherical blood, bone marrow aspirate and biopsy and confirmed by cytogenetic and molecular biology techniques.
Results: *Case number 1.* A 68 year old woman known to have essential thrombocythemia as a MPN, with V617F mutation of the JAK2 protein kinase. After 19 years of treatment by Hydrea, she developed a splenomegaly , anemia and slight lymphocytosis of 4.77 G/L. The blood smear, the bone marrow aspirate and biopsy examination revealed myeofibrosis evolution and an infiltration by 30% of a small sized clonal lymphoid population CD20+, CD5-.Medullar karyotype was normal: 46, XX[10].In conclusion the ET has evolved into myelofibrosis and is associated with a lymphoproliferative syndrome, possibly marginal zone lymphoma.No additional treatment has been implemented. *Case number 2.* A 64 year old woman know to have ET with V617F mutation of the JAK2 protein kinase treated by acetic salicylic acid. 5 years after, she presented with IgG kappa type monoclonal gammopathy up to 28 g/L, without any associated clinical manifestation nor cytopenia. Medullar blood was diluted but showed slightly atypical plasmocytes remaining under 10%.Myeloma was diagnosed anyway and the patient received 5 cures of Velcade-Melphalan-Prednisone which resulted in complete remission. The MPN remains stable to this day. *Case number 3.* A 62 year old man with chronic lymphoid leukemia, treated by six cycles of R-FC. While in remission since 2 years, hemogram shows hyperleucocytosis (WBC: 18.3 G/L) with thrombocythemia (platelets: 1886 G/L) without anemia (Hb: 13.7 g/dL).Blood smear examination reveals 3% of myelemia and basophilia (3,66 G/L).BCR-ABL transcript is positive in 43% and karyotype points out a 9;22 translocation. (46, XY, t (9 ;22) (q34 ;q11)[1] nuc ish (BLX3, BCRx3,ABL.con BCRX2)[48/100].) Before starting Nilotinib, cytoreductive treatment by Hydrea was decided. Treatment is under way.
Summary/Conclusions: The three cases described highlight the diverse situations observed in cases of combined MPN/LPD pathologies. MPN with secondary onset of LPD are most frequently encountered, as was the case with patients 1 and 2. Cases of preexisting LPD and late onset MPN are rare (1), and cases of simultaneous discovery of both pathologies even more so (3). Several hypotheses have been formulated to explain the frequency of onset of these pathological associations: genomic instability due to JAK2 protein kinase activation, or due to BCR-ABL mutation, or exposure to cytotoxic chemotherapy or radiations (3).

Myeloproliferative neoplasms - Clinical

PB2032

CLINICAL AND ANALYTICAL DIFFERENCES BETWEEN CALR TYPE-1 AND CALR TYPE-2 MUTATION IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS: A SINGLE CENTER STUDY

M. Sobas[1,*], M. Olejniczak[1], I. Andrasiak[2], M. Kruszewski[3], B. Jazwiec[1], J. Rybka[1], T. Wrobel[1], K. Kuliczkowski[1]
[1]Department of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Wroclaw Medical University, [2]WroMedica Research Center, [3]Wroclaw Medical University, Wrocław, Poland

Background: The JAK2V617F is a main molecular marker in myeloproliferative neoplasms (MPN) and is harbored in about 50-60% of essential thrombocythemia (ET) and primary myelofibrosis (PMF). Recently, CALR mutation was described in ET and PMF JAK2V617F negative patients. There are two main variants of CALR mutation: type 1 (a 52-bp deletion) and type 2 (a 5-bp insertion).
Aims: To compare clinical and analytical data of ET and PMF patients with CALR type-1 vs CALR type-2 mutation.
Methods: We performed a single center study on 471 patients: 87 PMF and 384 ET. The JAK2V617F mutation was analyzed in DNA from peripheral blood leukocytes by PCR ARMS method. In all JAK2V617F negative patients detection of CALR mutation was performed by fragment length analysis and the results were confirmed by sequencing. Statistical data analysis was performed using Statistica 12.5 software for Windows.
Results: From 384 ET patients 254 were JAK2V617F positive (66%), 80 were CALR positive (21%) and 51 were JAK2V617F and CALR negative (13%). From CALR positive patients: 36 (51%) had type-1, 34 (45%) type-2 mutation, and 10 (12%) type-3 mutation. From 87 PMF patients 56 were JAK2V617F positive (64%), 18 were CALR positive (21%) and 13 (15%) were JAK2V617F and CALR negative. From CALR positive groups: 13 (72%) had type-1 and 5 (28%) had type-2 mutation. Compared with ET carrying JAK2V617F mutation, patients ET CALR positive (type-1 plus type-2) had lower hemoglobin (13.3 *vs* 14.5 g/dl, p<0.001) and leukocyte (8.2 *vs* 9.7 G/L, p<0.001), higher platelet counts (1067 *vs* 800 G/L , p<0.001) but with no significant differences in frequency of thrombosis. In ET, CALR mutation was associated with increased odds of myelofibrotic transformation (odds ratio [OR]=2.61; 95% CI: 1.28 - 5.34; p=0.009) comparing with JAK2V617F positive patients. Patients ET CALR type-1 had higher leukocyte counts than ET CALR type-2 mutation (9.6 *vs* 7.3 G/L, p= 0.008), but we did not find significant differences in hemoglobin, platelet counts, frequency of thrombosis or myelofibrotic transformation. Within PMF, no significant differences were observed. Moreover in PMF, there was no significant differences between the JAK2V617F, CALR type-1 and type-2 mutation status respect to the International Prognostic Score System (IPSS).
Summary/Conclusions: 1. In our population, the frequency of JAK2 and CALR mutation was similar to previously described. 2. Compared patients with ET JAK2V617F positive, ET CALR positive (type-1 plus type-2) had higher platelet count but no higher frequency of thrombosis was observed. 3. Myelofibrotic transformation was more frequent in ET CALR positive *versus* JAK2V617F positive patients. 4. ET patients CALR type-1 *versus* type-2 had higher leukocyte count but there were no more significant differences between these two groups. 5. There were no significant differences within PMF group (to small number of patients). 6. In PMF patients, there was no relations between IPSS and mutational status (JAK2V617F, CALR type-1 and type-2).

ESSENTIAL TRHOMBOCYTHEMIA: STUDY OF TREATMENT LINES REQUIRED. EXPERIENCE OF A SINGLE CENTER

M. Berenguer[1,*], R. Pérez López[2], V. Cabañas-Perianes[2], M. Moya-Arnao[2], N. Ortega-López[3], E. Salido-Fiérrez[2], A. Martínez-Marín[2], E. Fernández-Poveda[2], J.M. Moraleda-Jiménez[2]
[1]Hematology, [2]Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain, [3]Internal Medicine, Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain

Background: Essential thrombocythemia (ET) is a chronic myeloproliferative neoplasm that shows similar survival prognosis as general population, with a very low rate of transformation to myelofibrosis and acute leukemia.
There are different treatments for these patients with optimal responses at first. For the first line, it is usually threated with hydroxyurea, although in young patients it is usually replaced by anagrelide / interferon.
There are publications of hydroxyurea side effects, especially cutaneous, but there are not many studies about how many lines of treatment are needed to control the disease.
Aims: Study type and lines of treatment needed in patients with ET in a cohort of patients from January 1997 to January 2017.
Methods: We studied patients diagnosed of essential thrombocythemia in one area of the region of Murcia from January, 1997 to January, 2017. Those who started treatment and those who needed change were analyzed, either by resistance or by intolerance.
Results: In our area we have registered a total of 152 patients diagnosed with ET. Of these, 71% (108 patients) have required at least one treatment line. Table 1 shows the number of treatment lines required for the control of the disease. As it is shown in the Table, more than 20% of treated patients needed a second line and 6,5% required more tan 2 lines. At last, Table 3 shows current treatment of ET patients.

Table 1. Number of line treatmentes required for disease control.

Treatment lines	N (%)
1	76 (70,3)
2	23 (21,2)
3	7 (6,48)
4	1 (0,92)
5	1 (0,92)

Table 2. Drugs used in patients with ET.

Treatment	N
Hydroxiurea	99
Anagrelide	31
Interferon	10
Busulfan	4
Melphalan	1
Danazol	1

Table 3. Current treatment of ET patients.

Current treatment	N
No treatment	34 (29 never treated, 5 no currently)
in treatment	108
Hydroxyurea	76
Anagrelide	22
INF	6
Busulfan	1
Danazol	1
Hydroxyurea + Anagrelide	2

Summary/Conclusions: This study highlights that, although ET has a very good prognosis, there is a significant percentage of patients that will need a change of treatment, either because of resistence or intolerance.

THROMBOTIC AND BLEEDING RISK FACTORS IN ESSENTIAL THROMBOCYTHEMIA

A. Zherniakova[1,*], I. Martynkevich[1], V. Shuvaev[1], L. Polushkina[1], M. Fominykh[1], V. Udal'eva[1], I. Zotova[1], D. Shichbabaeva[1], S. Voloshin[1], S. Bessmeltsev[1], A. Chechetkin[1], K. Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Thrombosis and hemorrhage are the main category of complications, that affects the overall survival (OS), quality of life and therapy option choice in essential thrombocythemia (ET). Molecular marker presence (*JAK2*V617F, *MPL, CALR*) or its absence (triple-negative status (TN)) in ET supposed to impact on the clinical course, thrombosis rate and ET prognosis.
Aims: The aim of this study was to investigate interactions between the presence of molecular marker, thrombosis/bleeding rates and the OS in ET.
Methods: Outpatient's charts of 240 ET patients, who had been diagnosed with ET at our institution according to WHO 2008 criteria. The following data were assessed: complete blood count, bone marrow biopsy results, bone marrow cytogenetic, the restriction fragment length polymorphism (RFLP) results used for *JAK2*V617F detection, in case of *JAK2*V617F-negative status the PCR-RFLP (*MPL* detection) and the direct sequencing (*CALR* detection) results. Different thrombotic/bleeding complications rates were analyzed. The OS in ET patients was compared according to molecular markers revealed.
Results: According to their mutational status 182/240 (75.9%) patients (pts) were *JAK2*V617F-positive (*JAK2*+); 30/240 (12.5%) – *CALR*-positive (*CALR*+): type 1 (*CALR1*+) – 13/30 pts (43.3%), type 2 (*CALR2*+) – 17/30 pts (56.7%). Only two pts were *MPL*-positive (*MPL*+) (0.8%), TN were 26/240 pts (10.8%). Among 240 pts 183 (76.3%) hadn't any thrombotic complication or bleeding event (no complications/NC), 57/240 (23.7%) had complications: 49/57 (85.9%) reported arterial or/and venous thrombosis, stroke or heart failure (thrombosis+) and 11/57 (19.3%) had bleeding events (hemorrhage+). Thrombotic complications in *JAK2*+ had 27.4% (50/182) pts, in TN – 30.7% (8/26) pts, in *CALR1*+ – 18.2% (2/11) pts and no cases of thrombosis were detected in *CALR2*+ and *MPL*+ subgroups (p<0,001). There were significant statistical differences in

median platelet count as follows: 742x10^9/l (thrombosis+) and 937x10^9/l (hemorrhage+) (p=0.003). No significant statistical differences in median hemoglobin and leukocyte count (p=0.75 and p=0.47) were detected. There were more than a half pts older than 60 years in groups NC (51%) and thrombosis+ (59%) and in group hemorrhage+ only 36% (p<0,001). Cardiovascular risk factors were reported in 24% pts (NC), 69% pts (thrombosis+) and 36% pts (hemorrhage+) (p<0,001). There were no significant statistical differences in follows risk factors as thrombosis >1000x10^9/l and leukocytosis >11x10^9/l (p=0.85 and p=0.72). No significant differences in OS among groups NC, thrombosis+ and hemorrhage+ (p=0.12) were found (Figure 1).

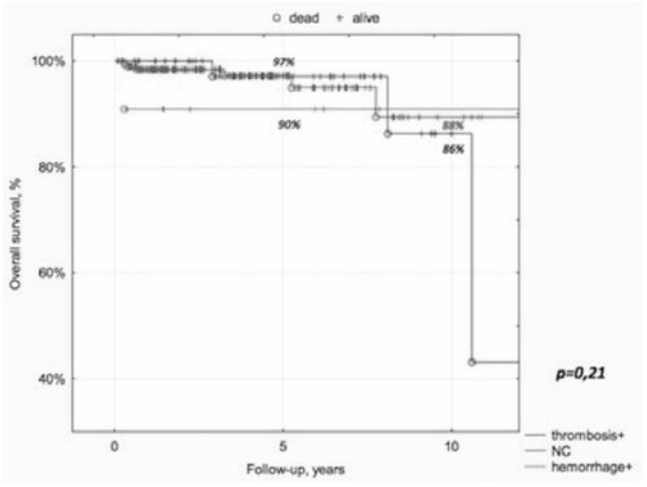

Figure 1.

Summary/Conclusions: Leukocytosis >11x10^9/l and thrombocytosis >1000x10^9/l cannot be assessed as independent thrombosis risk factors in ET. *JAK2*V617F mutation was associated with increased risk of thrombotic complications in ET. *CALR* mutations were correlated with lower thrombosis risk and better OS rate, comparing to *JAK2*+ and TN status despite the fact of *CALR*+ patients had higher platelets level. Along with common thrombosis risk factors (age >60 and cardiovascular risk factors) mutational status may help to identify ET course and to optimize individual therapy option choice.

PB2035

DETECTION OF JAK2 EXON 12 MUTATIONS BY HETERODUPLEX ANALYSIS AND PYROSEQUENCING

T. Subbotina[1,2,*], E. Dunaeva[3], K. Mironov[3], A. Kharsekina[1], E. Vasiyliev[2,4], M. Mikhalev[2,5], M. Osadchaya[6], M. Smelyanskaya[4], V. Khorzhevskyi[2,7], I. Olkhovskiy[2,8], G. Shipulin[3]

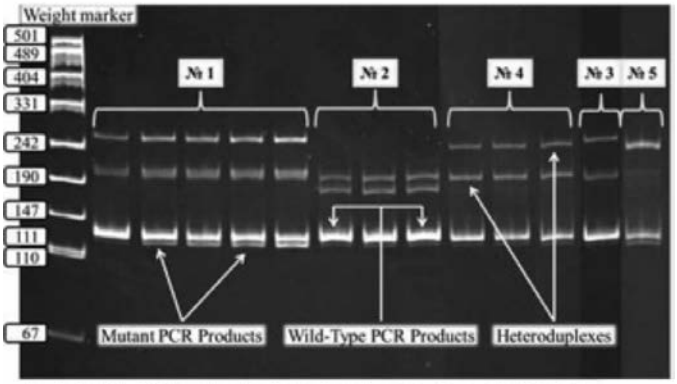
[1]Department of Medical Biology, Siberian Federal University, [2]Krasnoyarsk branch of the Federal State budgetary Institution «Hematology Research Center» Department of Health, Krasnoyarsk, [3]Federal Budget Institute of Science «Central Research Institute for Epidemiology», Moscow, [4]Krasnoyarsk regional hospital, [5]Municipal Budget Health Service Institution «City Clinical Hospital № 7», [6]Krasnoyarsk Territory Department of Health Regional state budget health facility «Krasnoyarsk interdistrict clinic №1», [7]Krasnoyarsk State Regional Bureau of Pathology, [8]Krasnoyask Scientific Center of the Siberian Branch of the Russian Academy of Sciences, Krasnoyarsk, Russian Federation

Background: Somatic mutations in codons 533-547 of JAK2 exon 12 are highly specific to confirm the diagnosis of polycythemia vera (PV). We have previously proposed techniques for the detection and quantification of JAK2 exon 12 allele burden using a pyrosequencing method (Subbotina T et al, Haematologica 2014). However, due to the high cost of sequencing, developing a two-stage algorithm for detect mutations in JAK2 exon 12 using inexpensive screening is of immediate practically necessity.

Aims: The aim of this study was to demonstrate the feasibility of using heteroduplex analysis with separation of the PCR product by electrophoresis on non-denaturing PAGE as the preliminary screening test for detection of JAK2 exon 12 mutations.

Methods: 274 patients with PV or unclear erythrocytosis and with a low JAK2V617F allele burden or unmutated JAK2V617 (51 women, mean age 52.2±15.7 years and 223 men, mean age 43.6±15.6 years) were included in this study. The informed consents from these patients were obtained. The PCR with the additional stage of formation heteroduplexes was performed using the Real-time PCR kit (Syntol, Russia) and CFX 96 Real Time System (Biorad, USA). PCR products were analyzed by electrophoresis in 8% PAGE. The presence of the mutations was identified and confirmed by pyrosequencing method with PyroMark Q24 (Qiagen, Germany). To verify the presence of mutations, the DNA sequences extracted from the clinical samples were cloned into pGem-T vector using standard protocol («Promega», USA), and obtained clones were sequenced using reagents and equipment of the «Applied Biosystems» (USA). JAK2 exon 12 variance^{MUT} was calculated as a measure of relative changes in allele burden between the baseline and follow-up sample (Theocharides A et al, Haematologica, 2008).

Results: We detected JAK2 exon 12 mutation in five out 274 patients. The results of electrophoresis on non-denaturing PAGE are reported in Figure 1. The type of №1-5 patient mutations was determined by pyrosequencing: N542-E543del (c.1624_1629delAATGAA); I540-E543delinsKK (c.1619_1627 TCAgAAATgK (c.1622_1627delGAAATG) and p.H538_K539>L (c.1612_1616CACAA>TT). These mutations have been already described. Main characteristics of 5 patients with JAK2 exon 12-mutated PV are reported in Table 1. The PV diagnosis of №1, 2, 3 and 5 patients was confirmed by bone marrow trephine biopsies histological examination. All five patients with JAK2 exon 12-mutated PV have an increased number of red blood cells, along with an accompanying increase in the concentration of hemoglobin and hematocrit level in the peripheral blood. Some of them had increase number of leukocytes and platelets in the disease dynamics. №1-4 patients was treated phlebotomy only and did not received any cytoreductive treatment to date. Patient №5 receives hydroxyurea (HU). Importantly, two out five patients with JAK2 exon 12-mutated PV also have a mutation JAK2V617 (<1%). JAK2 exon 12 allele burden in sample from №1 patient is significantly increased in the disease dynamics.



Analysis of the PCR product by electrophoresis on non-denaturing PAGE (in the disease dynamics for the №1, №2 and №4 patients).

Figure 1.

Table 1.

Characteristics of 5 patients with JAK2 exon 12-mutated PV.

№	Age of manifestation (years)	Sex	Disease	HU	JAK2 V617F mutation	JAK2 12 exon mutation	% JAK2 12 exon mutation baseline	% JAK2 12 exon mutation last sample	JAK2 12 exon variance MUT	Time between two assessments (mo)
1	61	M	PV*	No	Neg	N542_E543 del	15	50	+233	41
2	48	M	PV*	No	<1%	I540_E543 delinsKK	11	13	n.s.	15
3	27	M	PV	No	Neg	N542_E543 del	15	11	n.s.	43
4	~72	F	PV	No	Neg	R541_E543 >K	21	26	n.s.	36
5	29	M	PV	Yes	<1%	H538_K539 >L	30	-	-	-

* – The allele burden was determined at the primary address to the doctor with MPN symptoms

Summary/Conclusions: The proposed variant of the heteroduplex analysis with separation of the PCR product by electrophoresis on non-denaturing PAGE can be recommended for use as the preliminary screening test which is carried out before the confirming pyrosequencing. The two-stage approach allows to optimize the algorithm of the JAK2 exon 12 mutation detection and to improve the efficiency of testing for patients suspected of having PV in whom a JAK2V617F mutation is not detected or detected in a low allele burden. In five out 274 patients we detected JAK2 exon 12 mutation and confirmed the diagnosis of PV.

PB2036

INTRODUCTION OF AN NGS GENE PANEL INTO CLINICAL SERVICE FOR MYELOPROLIFERATIVE NEOPLASMS

A. Skowronska[1,*], J. Bryon[1], S. Clokie[1], Y. Wallis[1], J. Mason[1], K. Reay[1], M. Griffiths[1]

[1]West Midlands Regional Genetics Laboratory, Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom

Background: In the West Midlands region of the UK, all patients with a suspected myeloproliferative neoplasm (MPN) have access to quantitative analysis

of *JAK2* V617F by droplet digital PCR as standard of care. The British Committee for Standards in Haematology recommends that suspected MPN cases have investigation of *JAK2* exon 12, *CALR* and *MPL* genes if *JAK2* V617F is negative.
Aims: The aim of the project was to improve the MPN service by substituting sequential analysis of individual target regions within the *JAK2*, *CALR* and *MPL* genes with a single assay, and to increase the number of genes available for analysis.
Methods: A commercial next generation sequencing (NGS) gene panel (Oxford Gene Technology, SureSeq Myeloid Panel), coupled with the Illumina MiSeq platform was validated and implemented. The gene panel utilises hybridization based enrichment technology and consists of 25 MPN–related genes. During the validation stage the following were enriched and analysed: 29 positive control samples with 30 known pathogenic variants, 30 negative control samples without known pathogenic variants in the *JAK2, CALR and MPL* genes, and 24 MPN samples of unknown mutational status. Thus so far over 200 clinical samples have been analysed and reported since the service was introduced in October 2016.
Results: The panel has successfully identified: a large range of known pathogenic variants at high sensitivity (*JAK2* V617F variant allele frequency 1%, *CALR* Type I frameshift variant allele frequency 3%), a potential alternative driver mutation in a known low level *JAK2* V617F positive patient, a rare *MPL* exon 4 pathogenic variant and also the detection of low level *CALR* pathogenic variants, which would not have been detected by Sanger sequencing analysis. In one patient the panel identified the presence of two different *JAK2* exon 14 pathogenic variants in cis (*JAK2* V617F and *JAK2* C618R). The *JAK2* C618R prevented the hybridization of the probe binding site of the *JAK2* V617F ddPCR assay which had led to a false negative result by ddPCR. The validation procedure also explored coverage and limits of sensitivity, potential chemistry specific artefacts and identified common polymorphisms for all 25 genes.
Summary/Conclusions: The panel has replaced the current sequential analysis of *CALR, MPL* and *JAK2* exon 12 in *JAK2* V617F negative patients and reduced turn-around-times with increased accuracy and sensitivity compared to Sanger sequencing and fragment analysis. Our current clinical service operates on a two tier system whereby clinicians can request analysis of the full 25 gene panel or a 4 gene subset (*JAK2, CALR, MPL, CBL* as an *in silico* analysis).

PB2037

IN JAK2V617F POSITIVE MYELOPROLIFERATIVE NEOPLASMS, BLEEDING RISK CORRELATES WITH ALLELE BURDEN
I. Bertozzi[1,*], E. Cosi[1], C. Santarossa[1], G. Bogoni[1], F. Fabris[1], M.L. Randi[1]
[1]Dep. Internal Medicine - DIMED, University of Padova, Padova, Italy

Background: Myeloproliferative neoplasms (MPN) are characterized by the presence of JAK2V617F mutation that is almost invariably associated with polycythemia vera (PV), but also occurs in the majority of patients with essential thrombocythemia (ET) or primary myelofibrosis (PMF). JAK2V617F-positive patients display different laboratory and clinical features from JAK2-wild type, but no clear correlation was found between the JAK2V617F allele burden and natural history of the disease. The most common causes of morbidity and mortality in MPN are thrombotic and hemorrhagic complications, albeit bleedings are less frequent than thrombosis and mostly represented by minor hemorrhages (ecchymosis, epistaxis, menorrhagia and gingival hemorrhage). The impact of different allele burden on bleeding risk is uncertain.
Aims: Aim of our study is to explore whether there is an association between JAK2V617F allele burden and hemorrhagic complications in a large cohort of MPN diagnosed and followed in a single center.
Methods: We selected 253 MPN (121 ET= 47.8%, 124 PV=49% and 8 PMF=3.2%) carrying JAK2V617F mutation. The median follow-up of patients was 8.8 years (0.1 – 37.3 y). Complete medical history and anti-thrombotic drugs use were recorded. Hemorrhagic complications were classified as "major" or "minor" in agreement with ISTH criteria. The patients were categorized into four groups according to the amount of JAK2 mutant allele, (1st quartile 1-25%, 2nd quartile 26-50%, 3rd quartile 51-75% and 4th quartile 76-100%). Nominal variables were compared with X^2 test or Fisher's exact where indicated. Survival has been evaluated only for groups with different prevalence of events during follow-up and were calculated with the Kaplan Meier method and compared with the Log Rank test.
Results: Three patients (1.2%) bleed at diagnosis (1 major and 2 minor hemorrhages) while 27 (11.8%) suffered for hemorrhages during follow-up (10 major and 17 minor). Prevalence of hemorrhages results higher in 4th quartile compared both to 2nd (p=0.003) and to 1st (p<0.001) quartiles. Hemorrhages-free survival is confirmed lower in 4th quartile compared both to 2nd (p= 0.004) and to 1st (p<0.001). The incidence rate of hemorrhages are respectively 0.7/100 pats /y for 1st quartile, 0.65/100 pats /y for 2nd quartile, 1.26/100 pats /y for 3rd quartile and 3.23/100 pats /y for 4th quartile with a IRR of 5 and of 4.6 for the 4th quartile respectively *versus* 2nd and 1st one. No statistically significant difference has been demonstrated in the use of anti-thrombotic drugs among patients of the different quartiles.
Summary/Conclusions: Risk factors for hemorrhage in MPN are not well defined, and there is no risk estimation model for this outcome. Acquired von Willebrand disease, entity of platelet increased count and aspirin use have been implicated in bleeding occurrence. Previous reports fail to demonstrate a correlation between JAK2 mutation and bleeding risk. In contrast, in our cohort we found a significantly higher incidence of bleeding manifestations during follow-up in patients with higher allele burden. Interestingly no differences were seen in administration of anti-thrombotic drugs among quartiles, suggesting an independent role of JAK2 allele burden in the different distribution of hemorrhagic events.

PB2038

JAK2 ALLELE BURDEN IN PATIENTS WITH PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS
M. Napolitano[1,*], S. Siragusa[1], S. Mancuso[1], M. Santoro[1],
M.R. Lanza Caricio[1], M. Bono[2], F. Di Piazza[2], A. Russo[3], V. Accurso[1]
[1]UO Ematologia, [2]Laboratorio di genetica e oncologia molecolare, [3]UO Oncologia, University Of Palermo, Palermo, Italy

Background: The JAK2V617F allele burden (JAK-AB) plays a central role in chronic myeloproliferative neoplasms (cMPNs); its presence has also been advocated in the differential diagnosis of cMPNs and as independent risk factor for venous thromboembolic complications. New treatment with Ruxolitinib may decrease JAK-AB but at the present, it is not clear the clinical advantage of such reduction
Aims: Primary aim of the current study was to evaluate at diagnosis the JAK-AB in patients with Philadelphia negative cMPNs, in order to evaluate any association with standard demographic, clinical and laboratory parameters with particular reference to thrombotic risk.
Methods: Peripheral blood samples from patients with Ph-negative cMPNs were collected, DNA from leucocytes was analysed for Jak-2 (V617F) gene mutation with amplification-refractory mutation system (ARMS) PCR, subsequently a real-time quantitative polymerase chain reaction (qRT-PCR) for JAK2V617F allele burden measurement was applied. A multivariate analysis was than performed to evaluate any association of AB with demographic and clinical data.
Results: One hundred and twelve patients with Philadelphia negative cMPNs were investigated: 52 females with a median age at diagnosis of 69 years (age range: 18-95 years), 60 males with a median age of 68 years (age range: 18-82 years). Thirty-four patients had Essential Thrombocythemia (ET), fifty-two had Polycythaemia Vera (PV) and twenty-six had primary myelofibrosis (PMF). JAK2-AB of patients with an age of <69 years and ≥69 years, was respectively evaluated. Patients older than 69 years showed a significantly higher JAK2-AB . JAK-AB was significantly reduced in ET, when compared to PV and PMF. No correlation was found between median values of allele burden and IPSS and DIPSS scores. In patients with PV (n=52), a significant correlation was observed between allele burden and WHO2008 scoring system. No significant correlation was found between allele burden and thrombotic risk according to IPSET-t and IPSET-ET for PV and ET, respectively. Patients with a previous history of thrombosis had the highest JAK2-AB. In PMF, a positive correlation between JAK-AB and grading of fibrosis was found only for the highest grades (PMFIII and IV). JAK-AB had a positive correlation with splenomegaly in PMF.
Summary/Conclusions: Our report cannot confirm any correlation between allele burden and thrombotic risk, according to currently adopted scoring systems. A previous history of thrombosis is however associated with the highest AB in all cases.

PB2039

COMPARISON OF CLINICAL AND LABORATORY DATA, INCLUDING JAK-2 46/1 HAPLOTYPE, BETWEEN PATIENTS WITH IDIOPATHIC ERYTHROCYTOSIS AND POLYCYTHEMIA VERA.
M. Napolitano[1,*], S. Siragusa[1], M. Santoro[1], F. Di Piazza[2], M. Bono[2],
S. Mancuso[1], A. Russo[3], V. Accurso[1]
[1]UO Ematologia, [2]Laboratorio di genetica e oncologia molecolare, [3]UO Oncologia, University Of Palermo, Palermo, Italy

Background: Idiopathic erythrocytosis (IE) is a relatively rare finding characterized by an increased red blood cell mass without an identifiable cause. Diagnosis of IE is based on the exclusion of primary and secondary erythrocytosis including JAK2-wild-type polycythemia Vera (PV).
Aims: In the current study, we report clinical features and laboratory data able to discriminate IE from PV, at diagnosis
Methods: We have here analyzed clinical and laboratory parameters, including Jak-2 46/1 haplotype, from patients with a confirmed diagnosis of IE and PV, followed from January 2010 to December 2016. Data were statistically analyzed, nominal variables were compared with X^2 test and continuous variables with the Mann-Whitney test.
Results: Overall, 40 patients with IE and 93 patients with PV were included in the current analysis (Table 1). Splenomegaly and itch were reported only in one patient with IE. History of thrombosis and cardiovascular events was positive in one case with IE. Jak-2 (V617F) and exon 12 mutations were negative in all patients with IE, while Jak-2 46/1 haplotype was found at heterozygous state in 18 patients and at homozygous state in 2 patients with IE.

Table 1.

	PV	IE	p
Patients N.	93	40	
MALE N. (%)	59 (63,44%	38 (95%)	0.0001
FEMALE N (%)	34 (36.56%)	2 (5 %)	0.0001
MEDIAN AGE AT DIAGNOSIS, YEARS	66 (23 - 95)	58 (17 - 83)	0.007
SPLENOMEGALY N° (%)	38 (40,86%)	1 (2,5%)	0.000001
ITCH	36 (38,70%)	1 (2,5 %)	0.00000 1
MEDIAN WBC COUNT X10⁹	9,3 (4,535,2)	8.1 (4,2-14,3)	0.03
MEDIAN HB g/dl	17,5 (15,1-21,0)	17,4 (16,1-19.1)	0.9
MEDIAN HT %	53,3 (48.4 - 64.3)	52,4 (48.2 - 55.3)	0.1
MEDIAN PLTS COUNT X 10⁹	435.0 (270-1013)	216 (178.339)	0.001
V617 F OF JAK2 POSITIVE N. (%)	86 (92,47)	0	
JAK2 EXON 12 MUTATION N. (%)	2 (2,15%)	0	
HAPLOTYPE 46/1 OF JAK2, ETHEROZIGOUS	42 (45,16%)	18 (45,0%)	0,98
HAPLOTYPE 46/1 OF JAK 2, HOMOZIGOUS	25 (26,88%)	2 (5 %)	0.008
PATIENTS WITH CARDIOVASCULAR EVENTS OR THROMBOSIS N %	32 (34,4%)	1 (2,5%)	0.000008

Summary/Conclusions: In the current study, we highlight peculiar clinical and laboratory findings of IE, in comparison with Polycythemia Vera. As shown by available studies, Hb and HCT level do not easily discriminate between the two categories of patients while gene panels may be useful to improve diagnostic accuracy of IE. We have here first observed the presence of Jak-2 46/1 haplotype in approximately half patients with IE, even in absence of JAk-2 mutations; the homozygous status was statistically different among PV and IE patients. The role of such association deserves further specific studies.

PB2040

LABORATORY RESPONSIVENESS OF LOW-DOSE ASPIRIN IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

E. Cacciola[1,*], E. Gentilini Cacciola[2], R. Cacciola[3]
[1]Medical and Surgical Science and Advanced Technolgies, [2]Haemostasis Unit, Catania, Italy, [3]Experimental and Clinical Medicine, Haemostasis Unit, Catania, Italy

Background: The essential thrombocythemia (ET) is a myeloid neoplasm characterized by platelet hyperreactivity and thrombosis. The daily low-dose aspirin (ASA) is a cornerstone in the prevention of the thrombotic events. In the ET an accelerated platelet turnover translates in a renewal of the drug target shortening the duration of cyclooxygenase (COX-1) inhibition and may dictate new dosing strategies particularly in ASA "low-responders" patients.
Aims: Therefore, we evaluated platelet count, β-thromboglobulin (β-TG) and platelet factor 4 (PF4), as markers of platelet activation, the platelet function activity (PFA), as indicator of ASA platelet sensitivity.
Methods: We studied 60 patients (20 men, 40 women; mean age 51 years, range 32-70) with ET according to WHO criteria. The mean duration of disease was 11 years. All patients were on ASA 100 mg once daily. Of the 60 patients, 45 were on anagrelide hydrochloride (daily dose 1.5 mg) (10 men, 35 women), 15 were on hydroxyurea (daily dose 2 mg) (10 men 5 women). None had inherited or acquired thrombotic risk factors. Sixty subjects served as controls. Platelets were measured by automated analyzer. β-TG and PF4 were determined by ELISA. ASA platelet sensitivity was measured by Platelet Function Analyzer (PFA-100).
Results: The mean platelet count was 455±200x109/L. All patients had normal β-TG and PF4 ((12±5 IU/ml and 4±1 IU/ml) and prolonged C/EPI closure time (T, unit: s, n.v. 84-160 s) (249±40 s).
Summary/Conclusions: These findings suggest that in ET patients the daily low-dose ASA represents an optimal dosing strategy and that PFA test may be an useful tool to distinguish between the ASA "normal-responder" and "low-responder" ET patient.

PB2041

CLINICAL AND EXPERIMENTAL CHARACTERISTICS OF MYELOID/ LYMPHOID NEOPLASMS DISPLAYING PDGFRA OR PDGFRB REARRANGEMENT

L. Kou[1], J. Pan[1], H. Qiu[1,2,*], S. Chen[1], D. Wu[1,2]
[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, [2]Institute of Blood and Marrow Transplantation,Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: According to the 2016 revision to the WHO classification of myeloid neoplasms and acute leukemia, the cases with rearrangement of tyrosine kinase (TK) genes PDGFRA, PDGFRB are classified in Myeloid/lymphoid neoplasms with eosinophilia and rearrangement of PDGFRA, PDGFRB, or FGFR1, or with PCM1-JAK2. It is a rare event that patients presented rearrangements with these genes. And in the past decade, the dose of TKI to cases with PDGFRA and B abnormal was inconclusive.
Aims: The goal of the study was to assess the clinical and experimental characteristics and observe the response of Imatinib(IM) therapy of Myeloid/lymphoid neoplasms with PDGFRA or B abnormal.
Methods: Cytogenetic examination of bone marrow cells obtained from patients was performed by 24h culture method. R banding technical was used for karyotype analysis. PDGFRA and B gene rearrangement were detected by FISH using triple-color of 4q12 and dual color break-apart PDGFRB probes. The fusion genes of rearrangements of PDGFRA and B genes were detected by RT-PCR. Immunophenotype analysis was carried out by flow cytometry. Most of all cases were treated with IM and followed up.
Results: The diagnoses included 27 cases of MPN, 1 case of AML-M2 and 1 case of non-hodgkin lymphoma. 21 cases were PDGFRA rearrangement, the other 8 were PDGFRB abnormal, 7 of 8 were EP fused gene, one of which concurrent with DEK-CAN fused gene, and the eighth had MYO18A-PDGFRB. 7 cases of the 8 PDGFRB rearrangement had a primary abnormality with t(5;12)(q33;p13) and the other one had a secondary abnormality of AML-M2. PDGFRA and B genes rearrangement detected by FISH and multiple-RT-PCR were positive. The immunophenotypical analysis showed myeloid or lymphoid. These cases achieve rapid and durable remissions on IM.
Summary/Conclusions: In summary, patients with significantly anemia and eosinophilia should be screened for the presence of PDGFRA and B rearrangements. The dual-colour FISH is a simple approach and should be added into the diagnostic work-up because these patients respond to imatinib therapy, and sustained responses have been observed. The OS of PDGFRA and B abnormal was similar with a previous report in a western population and another Chinese hematology center.

PB2042

PLATELET AGGREGATION STUDY OF ESSENTIAL THROMBOCYTHEMIA TREATED WITH ANAGRELIDE

Y. Hiramatsu[1,*], K. Furukawa[2], K. Mizuhara[1], T. Sakayori[3], Y. Fujiwara[1], N. Mochizuki[1], S. Kubonishi[1], Y. Komiyama[3]
[1]Department of Hematology and Oncology, [2]Department of Pathology and Clinical Laboratory, Japanese Red Cross Society Himeji Hospital, Himeji, [3]Hemostasis Product Engineering, Sysmex Corporation, Kobe, Japan

Background: Essential thrombocythemia (ET) is a myeloproliferative neoplasm characterized by thrombocytosis and abnormal megakaryocyte proliferation. Patients with elevated platelet count are considered to be a high-risk group for thromboembolic and/or hemorrhagic complications. In Japan, anagrelide treatment was recently approved for the 1st line as a cell reduction therapy on ET. Even now, there are few study whether the risk of thrombosis has decreased after anagrelide treatment. Moreover, the platelet count problem uncertainty remains what is the best practice to follow when the platelet count in platelet-rich plasma (PRP) exceeds about 600 x10⁹/L, in the recent recommendations for the standardization of light transmission aggregometry by the platelet physiology subcommittee of Scientific and Standardization Committee /International Society of Thrombosis and Hemostasis.
Aims: The aim of this study was to characterize the platelet aggregation (PA) in patients with ET. We would also clarify whether there were any changes of hemostatic side effect and platelet aggregability before and after treatment with anagrelide.
Methods: This study has been conducted with blood sample obtained from six healthy subjects, compared to 18 consecutive patients with ET. None of the patients was taking anticoagulants or cytoreductive agents. We also studied six anagrelide-treated patients with ET. Whole blood aggregometry (WBA) and LTA using PRP were performed. ADP-induced PA or collagen-induced PA used natural count PRP and platelet count adjusted PRP with platelet-poor plasma. Data were compared in the groups using the Tukey-Kramer test. This study was approved by the Ethical committee of our hospital. All study procedures were performed in accordance with the Declaration of Helsinki.
Results: The result of WBA was not obtained, because the filter was obstructed by giant platelets. In the natural PRP, even over 900x10⁹/L, the platelet aggregability was markedly increased compared with the control (ADP-induced PA: p=0.023, collagen-induced PA: p=0.001), but, was not significantly different (ADP-induced PA: p=0.703, collagen-induced PA: p=0.986) in the count adjusted PRP. These results were not confirmed in cases with platelet counts of less than 600x10⁹/L. There was no decrease in platelet aggregation before and after treatment with anagrelide (ADP-induced PA: p=0.3403, collagen-induced PA: p=0.514).
Summary/Conclusions: In the ET patients with platelet counts more than 900x10⁹/L, the platelet aggregation by LTA with natural count PRP was remarkably accelerated and this data seemed to reflect the disease state. Although treatment with anagrelide showed cyto-reductive effect without any hemorrhagic complication in patients with ET, it did not fully reduce platelet aggregability.

PB2043

A SINGLE CENTRE EXPERIENCE OF MASTOCYTOSIS

G. Özkan[1,*], Ö. Tepe[2], N. Demir[1], Ö. Arslan[1], S. Erdem[1], Ö. Doğan[2], N. Büyükbabani[2], C. Baykal[3], R. Tanakol[4], M. Nalçaci[1], A.S. Yavuz[1]
[1]Hematology , [2]Pathology, [3]Dermatology, [4]Endocrinology and Metabolism, Istanbul Medical Faculty, İstanbul, Turkey

Background: Mastocytosis considered as a subcategory of myeloid neoplasms based on World Health Organization (WHO) 2016 classification, is characterized by expansion and accumulation of abnormal clonal mast cells in

one or more organs. KITD816V mutation and other KIT mutations play as driver mutations in the pathogenesis of disease. KITD816V mutation is positive in%80 of systemic mastocytosis patients. Recent studies show that high allele burden of KITD816V and high serum tryptase levels correlate with aggressive disease. Recently the importance of CD30 expression on neoplastic mast cells has been confirmed. CD30 is expressed aberrantly on neoplastic mast cells in patients with advanced systemic mastocytosis.

Aims: In this study we aimed to present demographic data, clinical follow-up and treatment of patients with mastocytosis and identify the impact of KIT D816V allele burden and expression of CD30 by mast cells in systemic mastocytosis.

Methods: We performed a retrospective study on 54 adult patients with mastocytosis (24 female, 30 male; mean age:44±13) who fullfilled WHO criteria between 2006 and 2016. These patients comprise cutaneous mastocytosis (CM) (n=10), ındolent systemic mastocytosis (ISM) (n=30), smoldering systemic mastocytosis (SSM) (n=2), aggressive systemic mastocytosis (ASM) (n=4) , systemic mastocytosis associated hematologic neoplasm (SM-AHN) (n=3), mast cell leukemia (MCL) (n=4) and mast cell activation syndrome (MCAS)(n=1).

Results: At diagnosis, age of patients with advanced disease was higher than ISM and SSM group (p=0.001). Most frequent symptom of disease was skin lesion (urticaria pigmentosa) (%64). Skin lesions were significantly higher in patients with ISM and SSM than with advanced disease (p=0.009). But B symptoms were significantly higher in advanced disease variant (p=0.013). Anemia, trombocytopenia, elevation of ALP and GGT, hypoalbuminemia were significantly higher in advanced disease than in ISM and in SSM. Osteopenia was higher in patients with ISM and SSM than with advanced disease,%56 and%18 respectively. KITD816V mutation was detectable in peripheral blood in 33 of 40 mastocytosis patients (%82) with a median Ct value 36±4. Median Ct value was significantly lower in advanced SM (Ct: 32±5) than in SM and SSM (Ct: 36±4)(p=0.028) showing a significantly higher allele burden. Expression of CD30 on mast cells in bone marrow biopsies with immunohistochemistry investigation was detectable in 20 of 32 systemic mastocytosis patients (%62). There was no significant difference expression of C30 on mast cell between patients with ISM (%65) (13/20) and advanced SM (%87) (7/8) (p=0.371). There was no significant correlation between elevated serum tryptase level and CD30 expression (p=0.114).

Summary/Conclusions: The definition of disease subcategories in systemic mastocytosis is important for choosing the treatment modality (cytoreduction or allogeneic stem cell transplantation *vs* treatment of the mediator symptoms) for the individual patient. CD30 is a diagnostic marker and also a possible therapeutic target.

PB2044

JAK2 PSEUDO-KINASE AND KINASE MUTATIONS IN THE ETIOLOGY OF THROMBOCYTOSIS

M. Coucelo[1,*], J. Azevedo[1], A.L. Pinto[1], A.T. Simões[1], S. Marini[1], T. Magalhães Maia[1], J.C. Almeida[1], A.I. Espadana[1], L. Ribeiro[1]
[1]Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Thrombocytosis is defined as an abnormally increased number of platelets (>450x10^9/L) in the blood counts, whose cause can be primary or secondary, hereditary or acquired. Hereditary thrombocytosis is a rare congenital disease due to germ line mutations affecting thrombopoietin signaling genes such as THPO, MPL and, more recently, JAK2.

Aims: To describe five cases of persistent thrombocytosis in young patients with *JAK2* mutations.

Methods: Four children (2F: 2M), median age of 8,8 years and 1 young adult (F) 21 years-old, with sustained elevation of platelet counts. None had previous history of thrombo-hemorragic events. Main causes of secondary thrombocytosis were excluded, and all patients tested negative for *BCR-ABL1*, *JAK2*V617F, *CALR* and *MPL* mutations. Sanger sequencing of exons 12 to 20 of JAK2 was performed in all patients. Family studies were possible in 3 families.

Results: Median CBC values: platelets- 630±90x10^9/L; hemoglobin - 13,3±1,2 g/dl and leukocytes- 9,3±2,3x10^9/L. Four different *JAK2* mutations were identified in the 5 patients (Table 1): *JAK2* S591L/R867Q/T875N/T875I. The patient with the *JAK2* T875N mutations had a discrete splenomegaly Familial studies allowed the identification of *JAK2* T875I mutation in 3 adults previously characterized as essential thrombocythemia (ET) triple negative

Summary/Conclusions: *In vitro* studies performed by other authors have demonstrated that *JAK2* R867Q and *JAK2* S591L, described in familial thrombocytosis, promote JAK-STAT activation. The germline nature of *JAK2* T875N mutation, previously described in an acute megakaryoblastic leukemia primary cell line, was confirmed in DNA obtained from hair follicle. Two patients presented a non-described *JAK2* T875I mutation. Familial studies clarified the etiology of thrombocytosis in 3 adults previously diagnosed as ET triple negative. The identification of different *JAK2* germline pseudo-kinase and kinase domains mutations has settled the etiology of persistent thrombocytosis in 4 children and 1 young adult. Therefore, particularly in children, after excluding the main causes of secondary and acquired thrombocytosis, *JAK2* gene sequencing should be incorporated in the differential diagnosis of this condition. The characterization of these rare forms of thrombocytosis and the follow up of these patients across generations, will improve the understanding of this entity.

COMPARISONS OF PATIENT MANAGEMENT IN MYELOPROLIFERATIVE NEOPLASM PATIENTS IN THE UK *VS* REST OF WORLD: ANALYSIS FROM THE INTERNATIONAL LANDMARK SURVEY

C. Harrison[1,*], Z. Pemberton-Whiteley[2], A. Mead[3], S. Ali[4], J. Mathias[5], C. Thomas[5], M. Campbell-Drew[5], G. Taylor-Stokes[6], J. Waller[6], A. Duces[7], B. Taylor[7]
[1]Guy's and St Thomas' NHS Foundation Trust, Guy's Hospital, London, [2]Head of Campaigns and Advocacy, Leukaemia CARE, Worcester, [3]Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, [4]Queens Centre, Castle Hill Hospital, Cottingham, [5]MPN Voice, London, [6]Adelphi Real World, Bollington, [7]Haematology Franchise, Novartis Pharmaceuticals, Camberley, United Kingdom

Background: Patient (Pts) with myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), experience a substantial disease burden. The international MPN LANDMARK survey evaluated the patient-reported impact of MPNs in pts across 6 countries and identified current treatment strategies in these pts.

Aims: To analyze differences in treatment strategies used by physicians and pts to manage their MPN between the UK and the Rest of Surveyed World (ROSW).

Methods: A cross-sectional survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK. The Internet-based survey was administered separately to MPN patients and treating physicians (the two samples were not linked). Observed differences between the UK and ROSW are described in terms of treatment patterns and patient physician communication.

Results: A total of 699 pts (UK, n=286; ROSW, n=413) and 219 physicians (UK, n=31; ROSW, n=188) completed the survey. UK physicians were more likely to start treatment rather than delay at diagnosis of PV or ET. A greater proportion of ROSW physicians reported they would observe >25% of patients at diagnosis (UK - 54% MF, 30% PV, 37% ET; ROSW – 51% MF, 48% PV, 50% ET). No difference was observed in the most commonly received treatments for each disease, but a greater proportion of UK patients reported receiving treatments than ROSW. This difference was greater in PV and ET than MF. For MF the most commonly received treatments were ruxolitinib (UK 55%, ROSW 50%), aspirin (UK 53%, ROSW 37%), hydroxyurea (HU) (UK 31%, ROSW 28%) and transfusion (UK 27%, ROSW 23%), for PV they were aspirin (UK 83%, ROSW 58%), phlebotomy (UK 76%, ROSW 67%) and HU (UK 63%, ROSW 36%) and for ET they were aspirin (UK 94%, ROSW 52%), HU (UK 62%, 30% ROSW) and anagrelide (UK 14%, ROSW 18%). Physician reported data on treatments prescribed demonstrated a similar pattern as a greater proportion of UK physicians reported using treatments than ROSW. UK physicians reported that their patients were more likely to 'often' disagree with their primary treatment recommendation than ROSW (16% *vs* 7%) but despite this UK patients were more likely to be 'completely' satisfied with their physicians understanding and support of their treatment goals (UK, 51%; ROSW 35%). Patients rated who they thought should be the main decision maker on a scale of 1 (the patient) to 10 (physician). UK patients were slightly more inclined to want to be involved in treatment decisions (mean: UK, 6.25; ROSW, 7.01). UK physicians supported this as more 'agreed strongly' with the statement '*I involve my MPN patients in treatment decisions"* (UK, 39%; ROSW 28%).

Summary/Conclusions: In comparison with ROSW: UK physicians were more likely to prescribe drug treatments for ET/PV. Interestingly, UK patients desired to be more involved in treatment decisions, and this was reflected in the physician's perspective to involve their patient in treatment decisions more. UK patients were also more likely to disagree with their physician on primary treat-

ment recommendations. However, this had no impact on satisfaction suggesting that UK patients welcome an open discussion on treatment options with their physician. These data highlight the importance of maximizing patient physician communication in order to improve patient satisfaction with treatment in the UK.

PB2046

ANALYSIS OF EMERGING MOLECULAR SIGNATURES AND ASSOCIATED CLINICAL FEATURES IN MPN

S. H Al Shemmari[1,*], R. Rajan[2]
[1]Department of Medicine, Kuwait University, [2]Bone Marrow and Stem Cell Transplant Lab, Kuwait Cancer Center, Kuwait, Kuwait

Background: Myeloproliferative neoplasms (MPNs) are a group of clonal hematological disorders that arise from transformation of a multipotent hematopoietic stem cell which includes polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF).Driver mutation's confer growth advantage on the cancer cell and most likely is selected in the tissue microenvironment within which the neoplastic cells arise. Three-quarters of these patients carry the unique JAK2V617F mutation, JAK2 exon 12 mutations are found in 5% of patients with PV, MPL exon 10 mutations are present in about 5% ET/PMF and CALR mutations are found in 50-70% patients with ET/PMF.
Aims: In this study we investigated the prevalence of these so called driver mutations in patients with MPN's from January 2007 – January 2017 reported in our center.
Methods: We analyzed 3000 samples with suspected MPN for JAK2V617F mutation by ARMS-PCR and their allele burdens were reported by RQ-PCR. We have screened a cohort of 500 patients for JAK2/MPL/CALR mutations by a sequential molecular analysis which includes PCR, RT-PCR and fragment analysis.
Results: JAK2V617F mutation is present in 50% of patients with MPN. Among 600 cases submitted for sequential molecular analysis identified 372 cases with JAK2V617F mutation, 70 cases with CALR mutation, and 6 cases with MPL mutations. Allele burden study on JAK2V617F positive patients revealed that patients with ET has the lowest allele burden, those with PV an intermediate one and those with PMF showed the highest burden. Measurement of JAK2V617F allele burden by RQ-PCR for a PMF case after allogeneic transplant (ASCT) reported that allele burden of 2.9% after 20 days of transplant and a negative result after 60 days of transplant *vs* 13% before ASCT.CALR mutation is found in ET and PMF cases that are mutually exclusive with JAK2V617F and MPL exon 10 mutations in ET whereas 2 cases with PMF found to be positive for JAK2V617F and CALR mutations. We found 40 cases with a 52-bp deletion, 4 cases with a 14bp deletion and 26 cases with a 5bp insertion. CALR variants reported in our cohort were 54% type 1 and 46% type 2 mutations. We found a tendency towards older age among type 2 carriers compared to type 1 carriers (median age at diagnosis: 57 years *versus* 52 years) or compared to non-type 2 carriers (median age at diagnosis: 57 years *versus* 53 years). Similarly, platelet count at diagnosis tended to be higher in the subgroup of type 2 mutation carriers than in patients with the type 1 mutation while hemoglobin levels and white blood cell count were lower compared to those with non-type 2 mutation. The mutual allele burden of JAK2V617F /CALR exon indel mutations of two PMF patients found as 10%/65% and 15%/55% respectively. In our cohort, 10% of the patents with CALR mutation had anemia, 21% had splenomegaly, and 43% had megakaryocytes at time of diagnosis. Compared with JAK2 V617F-positive ET and PMF, CALR-mutant ET and PMF are clinically correlated with lower WBC, leukocyte and hemoglobin counts, higher platelet counts, and a reduced risk of thrombosis.
Summary/Conclusions: Analysis of JAK2/MPL/CALR genes as molecular marker's for MPN's, allows the diagnosis of 95% of patients with MPN.As a novel mutation, CALR testing also has a prognostic significance and it was not mutually exclusive with JAK2V617F mutation. Measurement of *JAK2* V617F allele burden early after transplantation is an important predictive parameter in monitoring patients following this treatment.The knowledge of driver mutations can provide valuable information for diagnosis and prognosis, which ultimately can be highly useful for clinical decision making for the management of patients with MPN.

PB2047

IMPACT OF THE TYPE OF CALR MUTATIONS ON THE CLINICAL AND LABORATORY FEATURES OF ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS

E. Lisina[1,*], P. Butylin[1], N. Siordia[1], A. Silyutina[1], E. Lomaia[1], A. Zaritskey[1]
[1]Federal Almazov North-West Medical Research Centre, St. Petersburg, Russian Federation

Background: In 2013, in the majority of JAK2V617F negative patients with essential thrombocytosis (ET) and primary myelofibrosis (PMF) have been identified mutations in the 9 exon of CALR gene. Described more than 30 different mutations, subdivided into two subtypes: deletions (type I) and insertions (type II). There are data on the phenotypic effects, depending on the version of CALR mutations. However, the prognostic significance of mutations CALR is still insufficiently clear.
Aims: To assess the impact of the type I and type II mutations of CALR on the clinical and laboratory features of ET and PM.
Methods: A multicenter retrospective study was carried out. Samples of peripheral venous blood was obtained from 149 patients with ET (n=76) and PMF (n=73). Patients that were negative for JAK2V617F and MPL515L/K mutations were studied for CALR mutations presence as described in original paper (T.Klampf, 2013). CALR Mutations were detected in 34 patients with ET (10 - men, 24 - women) and 25 patients with PMF (13 - men, 12 - women). Statistical data processing was carried out in the program STATISTICA for Windows 6.0.
Results: The frequency of mutations CALR was comparable in patients with ET and PMF (44.7% and 35.6%). Mutations of type II is 2 times more common in ET than with the TFM: 17.1% *vs* 9.6% (p=0.178). Mutations of type I detected in 21 cases in ET, in 18 cases - in PMF, type II in 13 cases - in ET and 7 - in PMF. The median of follow-up period of patients with ET with type I mutation was 36 months (3-87), with type II - 22 months (2-90). In PMF, the median of follow-up in the group with type I mutation was 46 months (3- 133), type II - 77 months (4-115). Hematological parameters in patients with ET showed higher levels of WBC in patients with type I mutation (p=0.043), the level of Hb in this variant was lower (p=0.009). In PMF levels of Hb were similar in the studied groups. Type of mutations had no significant effect on the number of WBC in patients with PMF. However, PLT was higher in PMF patients with type II mutations of CALR (p=0.014). Spleen size in ET patients on the time of the diagnosis date was slightly different: in type I - 106,5mm, type II - 119,6mm (p=0.076). The type of mutation in our study had no effect on the stratification according to the IPSET. Also there were no significant differences in assessing of the effect of therapy. Spleen size on the time of the diagnosis date in PMF patients with type I mutation were slightly larger (180,9mm *vs* 169,9mm). Revealed more pronounced fibrotic changes of the bone marrow (BM) in patients with type I CALR mutations (p <0,005). CALR mutation type had no influence on the distribution of patients with PMF, depending on the risk groups on the scale of IPSS and DIPSS.
Summary/Conclusions: The effect of the type of CALR mutation on the clinical and laboratory features of the ET and PMF has found. Type of CALR mutations in our study had no effect on the number of PLT in ET, but have a value for this index in PMF. Type I mutations in ET accompanied higher WBC level and a lower level of Hb. The published studies have not shown the influence of the type of mutation in the Hb level and the number of WBC in ET. An important observation was the detection of the effect of type I mutations on development fibrotic changes of BM in PMF. Our data are consistent with previously published studies that showed no effect on the stratification of patients according to the scale on the IPSS.

THE UNIQUE CASE OF GERMLINE CEBPA MUTATION IN PATIENT WITH FIP1L1/PDGFRA ASSOCIATED MYELOID/LYMPHOID NEOPLASM WITH EOSINOPHILIA

N. Gabeeva[1,*], E. Zvonkov[1], E. Parovichnikova[2], D. Koroleva[1], O. Gavrilina[2], S. Kusnetsova[3], L. Grebenuk[4], T. Obukhova[4], A. Kovrigina[5], L. Kuzmina[6], V. Savchenko[3]
[1]Scientific and clinical department of chemotherapy for lymphomas, [2]Scientific and Clinical Department of Hemoblastosis Chemotherapy, Hemotopoietic Depression and Bone Marrow Transplantation , [3]National Research Center for Hematology, Moscow, Russian Federation, [4]cytogenetics department, [5]Department of Pathological Anatomy, [6]Department of bone marrow transplantation, National Research Center for Hematology, Moscow, Russian Federation

Background: Myeloid/lymphoid neoplasms with eosinophilia (MLNe) associated with PDGFRA rearrangement are rare disorders. The most frequent PDGFRA abnormalities is FIP1L1/PDGFRA (F/P) fusion gene results from a cryptic interstitial deletion at 4q12 with constitutive activation of tyrosine kinase (TK) activity. Although known since 2003, many questions remain in understanding the biology, disease course and response to therapy. The F/P fusion gene may clinically present as chronic eosinophilic leukemia (CEL), T-cell lymphoblastic lymphoma (T-LBL) or both concurrently. Acute myeloid leukaemia (AML) may also occur at presentation or during the course of the disease. While F/P is the driver mutation, to date there are few data about genetic variants of the disease that may contribute to clinical outcome. CCAAT/enhancer binding protein alpha (CEBPA) gene functions as key regulator of granulocytic differentiation. CEBPA mutations contribute to leukemogenesis by promoting proliferation and blocking differentiation of myeloid lineage in AML. Germline CEBPA mutations is a very rare and account about 1% in AML only.
Aims: We present the first case of detection of familial germinal CEBPA muta-

tion in a patient with F/P MLNe who received related allogeneic transplantation from brother.
Methods: A 26 year-old male patient was presented with a 4-week history of fever, fatigue, difficulty in swallowing. Physical examination revealed generalized lymphadenopathy, splenomegaly, tonsils enlargement, leukocytosis ($20x10^9$/L), with marked eosinophilia ($4,0x10^9$/L). A bone marrow aspirate showed 2% blasts, 21% eosinophils. Histological examination of an cubital lymph node biopsy showed diffuse proliferation of medium-sized lymphoblasts. Immunohistochemistry and flow cytometry showed that the lymphoblastic population expressed CD2, CD5, CD7, CD4, CD99, TdT and CD1a. Polymerase chain reaction (PCR) analysis from samples of the lymph node and bone marrow failed to detect clonal T-cell receptor rearrangement. A diagnosis of T-cell lymphoblastic lymphoma (T-LBL) associated with reactive eosinophilia was rendered. The patient began standard multiagent chemotherapy in accordance with ALL-2009 protocol (ClinicalTrials.gov Identifier: NCTO1193933) and achieved complete clinical remission. As he was planned to conduct autologous hematopoietic stem cell transplantation (HSCT), blood hematopoietic stem cells have been successfully harvested after stimulation of hematopoiesis. However, within 10 days after the discontinuation of G-CSF he developed leukocytosis ($130x10^9$/L) with 21% of eosinophils (absolute number $27,3x10^9$/L) and cubital lymphadenopathy. Histological examination of lymph node showed T-LBL relapse. Bone marrow biopsy revealed the expansion of predominantly eosinophilic cells. The study was carried out to exclude second myeloproliferative disease. Molecular and cytogenetic examinations of bone marrow failed to reveal BCR-ABL, FLT3 and NPM1, but showed CEBPA (TAD2) mutation. FISH probe revealed deletion 4q12 (F/P rearrangement), confirmed by RT-PCR. The same changes were also found in the lymph node cells. So, in accordance with 2008 WHO classification, he was diagnosed as «PDGFRA-associated MLNe». The patient was subsequently treated with imatinib mesylate at the dose 100mg daily and showed a good clinical response. After 4 months minimal residual disease still persisted in bone marrow (RT-PCR positive for F/P and PCR for CEBPA mutation) and he received an allogeneic HSCT from his brother. Routine testing of chimerism at 2 months after HSCT revealed the recipient DNA less than 5% and positive probe for F/P and CEBPA. We hypothesized the germinal origin of CEBPA mutation.
Results: The same N-terminal (TAD2) CEBPA mutation was found in the patient`s skin, lymph node and bone marrow, and in the patient's brother bone marrow samples. Unfortunately, no materials from parents was available for analysis at that time.
Summary/Conclusions: Germline CEBPA mutations is very rare event and have been identified as causative gene mutations in familial AML. For the first time to our knowledge this mutation was detected in patient with PDGFRA-associated MLNe. This observation is of particular interest because it will provide novel insight about the genetic basis and the additional events responsible for the course of the disease.

DEVELOPMENT AND DESIGN OF A RANDOMIZED CONTROLLED TRIAL USING ONLINE YOGA FOR SYMPTOM MANAGEMENT IN MYELOPROLIFERATIVE NEOPLASM PATIENTS

J. Huberty[1,*], R. Eckert[1], K. Gowin[2], B. Ginos[2], H. Kosiorek[2], A. Dueck[2], L. Larkey[3], R. Mesa[2]
[1]School of Nutrition and Health Promotion, Arizona State University, [2]Mayo Clinic, [3]College of Nursing and Health Innovation, Arizona State University, Phoenix, United States

Background: Patients with myeloproliferative neoplasms (MPNs) suffer from symptom burdens (*i.e.* fatigue, weight loss, night sweats, insomnia, sexual dysfunction, and pruritus) often not alleviated by JAK inhibition. We previously demonstrated feasibility of an online, home-based yoga 12 week intervention, in MPN patients on stable medical therapy. Specifically, online yoga was feasible in MPN patients (N=38) (*i.e.*, 68% satisfied with study, 75% felt it was helpful for symptom management and weekly yoga participation averaged ~51 min/week) and effective to alleviate residual MPN symptom burden (effect size [ES]=-0.36, p=0.004), anxiety (ES=-0.67, p=0.002), depression (ES=-0.41, p=0.049), sleep (ES=-0.58, p<0.001), and fatigue (ES=-0.33, p=0.04).
Aims: To conduct a randomized controlled pilot study further investigating the preliminary effects of online streamed yoga to improve MPN patient symptom burden compared to a wait-list control and to determine the feasibility (*i.e.*, implementation, practicality) of collecting biomarkers that are potentially related to MPN symptoms and disease (*i.e.* inflammatory cytokines and cortisol) in a national study. The study is underway with early feasibility data reported herein; efficacy results to be reported at conference upon study completion.
Methods: MPN patients (on stable medications including JAK inhibition) were recruited (via online MPN organizations) and randomized to a yoga group (intervention - 12 weeks, 60min/week at Udaya.com) or wait-list control (usual care). The yoga "intervention" was developed with MPN-specific concerns in mind (*i.e.*, enlarged spleen/liver, older adult population) and based on feedback received from our feasibility study. Weeks 1-2 were introductory (5-6, 5-10 min videos), with weeks 3-12 progressing in video duration and intensity (2-3, 20-30 min videos). All participants completed weekly activity logs, symptom burden questionnaires (MPN-SAF TSS and NIH PROMIS) at weeks 0,7,12, and 16 (follow-up), and wore a Fitbit Flex (objective activity and sleep monitor) through week 12. The yoga group only was also asked to receive a blood draw (*i.e.*, CBC, TNF-a, IL-6) and to provide saliva samples (*i.e.*, salivary cortisol) at baseline and will be expected to do so at post-intervention. Control group participants are asked to maintain usual levels of activity and will have access to the same videos as the yoga group after follow-up (week 16).
Results: A total of 260 MPN patients completed the eligibility questionnaire, of which 96 were eligible. Of those, the first 62 eligible were enrolled into the study (completed an informed consent). Thirty-four participants were randomized to the intervention group and 28 to the control group. Of those enrolled (n=62), 31% were diagnosed with PV (n=19), 37% with ET (n=23), and 32% with MF. The mean age of participants is 57.8 years (±10.3), 87% female (n=54), 95% Caucasian (n=59), and the mean BMI is 26.8 kg/m^2. A total of 85% (n=29/34) of yoga group participants completed the baseline blood draw and 83% (n=15/18 eligible for saliva samples) completed the baseline saliva sample. Of those that completed their blood draw (distance travelled to receive blood draw ranged from 1.2 miles – 91.6 miles, avg. 16.3 miles). To date, seven participants have dropped out of the study due to: 1) study too time consuming/laborious (n=1), 2) Fitbit device being too difficult to use/wear (n=1), 3) non-study personal issue (n=2), or 4) never responding after completing the informed consent (n=2). Outcomes will be complete by May 8, 2017 with results to be presented at EHA.
Summary/Conclusions: Data presented here will inform next steps for a RCT investigating the effectiveness of online yoga for symptom management in MPN patients.

PB2051

COMPARISONS OF SYMPTOM BURDEN IN MYELOPROLIFERATIVE NEOPLASM PATIENTS IN THE UK *VS* REST OF WORLD: ANALYSIS FROM THE INTERNATIONAL LANDMARK SURVEY

C. Harrison[1,*], Z. Pemberton-Whiteley[2], S. Ali[3], A. Mead[4], J. Mathias[5], C. Thomas[5], M. Campbell-Drew[5], G. Taylor-Stokes[6], J. Waller[6], A. Duces[7], B. Taylor[7]
[1]Guy's and St Thomas' NHS Foundation Trust, Guy's Hospital, London, [2]Head of Campaigns and Advocacy, Leukaemia CARE, Worcester, [3]Queens Centre, Castle Hill Hopsital, Cottingham, [4]Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, [5]MPN Voice, London, [6]Adelphi Real World, Bollington, [7]Haematology Franchise, Novartis Pharmaceuticals, Camberley, United Kingdom

Background: Patients with myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), experience a substantial disease burden. The international MPN LANDMARK survey evaluated patient-reported impact of MPNs across 6 countries.
Aims: To analyze differences in disease and symptom burden of MPN patients between the UK and the Rest of Surveyed World (ROSW).
Methods: A cross-sectional survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK. The internet-based survey was administered separately to MPN patients and treating physicians (the two samples were not linked). Observed differences between the UK and ROSW are described in terms of symptom burden.
Results: A total of 699 pts (UK, n=286; ROSW, n=413) and 219 physicians (UK, n=31; ROSW, n=188) completed the survey. UK patients reported more symptoms than those in ROSW (9.02 *vs* 5.95 respectively). A higher proportion of UK patients reported experiencing symptoms compared with ROSW (*e.g.* fatigue and tiredness UK - 87% MF and PV, 86% ET; ROSW – 64% MF, 39% PV, 45% ET). This pattern was observed for 28 of the 31 symptoms recorded. A similar difference was seen when physicians were asked about frequency of patient-reported symptoms (*e.g.* fatigue and tiredness UK – 90% MF, 67% PV, 70%; ROSW – 71% MF, 55% PV, 48% ET). Patients rated symptom severity from 1 (not severe at all) to 10 (worst possible). The UK was higher than ROSW for the three most common symptoms; fatigue and tiredness (mean: UK 6.73, ROSW 6.18), difficulty sleeping (mean: UK 6.09, ROSW 5.38) and loss of concentration (mean: UK 6.01, ROSW 5.67).This difference was not observed when physicians were asked to rate symptom severity. An overall symptom burden was calculated as a function of all patient-reported symptoms. UK patients were disproportionately represented in the high symptom burden group (UK 35% *vs* ROSW 16%) and had an average overall symptom burden score of 40.1 compared with 24.1 among ROSW patients. UK patients were also more likely to have been classified with a high risk score at diagnosis (UK 22% *vs* ROSW 9%). Despite the consistently greater symptom burden experienced by UK patients, little difference was observed in patient satisfaction with their physician's communication (UK 81% satisfied *vs* ROSW 90%) and disease management (UK 87%, ROSW 90%). However, UK patients were more likely to disagree with the statement '*My doctor understands how much my condition impacts my life*' (UK 39% *vs* 22% ROSW). UK physicians had more MPN patients under their care than ROSW (mean patients under care in last 12 months; UK - 25 MF, 46 PV, 47 ET; ROSW - 15 MF, 31 PV, 20 ET) and were also more likely to agree with the statement '*There is not enough time during the appointment to discuss all of the symptoms a patient is experiencing'* (UK 74% *vs* ROSW 54%).

Summary/Conclusions: UK patients perceive a higher symptom burden than ROSW in terms of frequency and severity. While UK physicians agree with regards to frequency, they didn't perceive a greater symptom severity in their patients compared to ROSW physicians. Patient/physician disconnect was unlikely to be the cause as satisfaction was high and similar to that in ROSW. However, UK physicians not only have more patients under their care than their ROSW counterparts, they are also more likely to feel they don't have enough time to discuss all symptoms. This is likely to be impacting on the ability of patients and physicians to communicate fully on symptoms and to agree on the best disease management plan.

PB2052

MPN10 SCORE AND SURVIVAL OF MOLECULARLY ANNOTATED MYELOPROLIFERATIVE NEOPLASMS PATIENTS; A FIRST REPORT ON AN EGYPTIAN COHORT

Y. Elnahass[1,*], H. Mahmoud[1], M. Mattar[2], O. Fahmy[2], M. Abdelmoaty[1], R. Abdelfattah[1], F. Elrefaey[1], W. Elmetenawy[2]
[1]Haematology, National Cancer Institute- Cairo University, [2]Haematology, Faculty of Medicine- Cairo University, Cairo, Egypt

Background: The vast majority of myeloproliferative neoplasms (MPNs) patients are characterized by a molecular genetic background and by variable symptoms reflecting disease burden that may correlate with prognosis.
Aims: To study the impact of driver gene mutations: Janus kinase 2 (JAK2), calreticulin (CALR) and myeloproliferative leukemia virus oncogene (MPL) on disease burden and correlating mutational status with symptom severity calculated by MPN10 score, degree of bone marrow (BM) fibrosis, clinical characteristics and survival in MPNs patients.
Methods: MPN Symptom Assessment Form Total Symptom Score (MPN-SAF TSS) was assessed as mean/median of 10 items: fatigue, concentration, early satiety, inactivity, night sweats, itching, bone pains, abdominal discomfort, weight loss and fever. $JAK2^{V617F}$and exon12 mutations were performed by allele-specific oligonucleotide polymerase chain reaction (ASO-PCR) while $CALR^{exon9}$ insertion/deletion and MPL $W515^{exon10}$ mutations were assessed by high-resolution melting (HRM).
Results: 93 MPNs patients (48 males and 45 females): 18 polycythemia vera (PV), 41 essential thrombocythemia (ET), 24 primary myelofibrosis (PMF), 10 Post-ET/PV-myelofibrosis (post-ET/PV-MF) were included. Median age at diagnosis was 55 years (17-75) and was lower in ET than PV and PMF patients; 44 (19-75) years *vs* 56 (34-70) years and 56 (20-75) years, respectively (p<0.001). JAK2 mutation was positive 53/93 (57%); 16 (90%) PV patients, 14 (34%) ET patients, 15 (62%) PMF patients, 8(80%) post-ET/PV-MF patients (p<0.001). CALR mutation was positive in 14/93 (15%); 10 (24%) ET patients, 4 (17%) PMF patients, zero (0%) Post-ET/PV-MF patients (p=0.050). MPL mutation was positive in 3/93 (3%); 2 (5%) ET patients, 1(4%) PMF patients, zero (0%) Post ET/PV-MF patients. 23/93 (25%) patients were triple negative; 15 ET, 2 PV, 4 PMF and 2 post ET-MF. Median MPN10 score was 21 (4-45) in ET *versus* 37.5 (25-56) in PV, 54 (15-80) in PMF and 59 (45-75) in Post-ET/PV-MF (p<0.001). From 39 patients with BM fibrosis, 6 (15%) were triple negative *vs* 33 (85%) mutant patients (p=0.007). Among 52 patients with splenomegaly; 7 (13.5%) patients were triple negative *vs* 45 (87%) patients with a positive mutational status (p<0.001). Median MPN10 score was 48 (5-76) in JAK2 positive patients *vs* 25 (4-80) in JAK2 negative (p<0.001) and was 22.5 (4-65) in CALR mutants *vs* 35 (5-80) in CALR negative (p<0.050). Median MPN10 score was 21 (10-48) in triple negative patients *vs* 40 (4-80) in MPNs JAK2/CALR/MPL mutants (p<0.001).After a median follow-up period of 36 months (6.6-102), progression free survival (PFS) and overall survival (OS) of the whole cohort was 85% and 95%, respectively. PFS of JAK2 positive *vs* negative patients was 62% *vs* 100% (p<0.001). PFS of CALR positive *vs* negative patients was 100% *vs* 78% (p=0.067). PFS of triple negative *vs* mutant patients was 100% *vs* 75% (p=0.004). OS of JAK2 positive *vs* negative patients was 85% *vs* 100% (p=0.011). OS of CALR positive *vs* negative patients was 100% *vs* 92% (p=0.197). OS of triple negative *vs* mutant patients was 100% *vs* 90% (p=0.015) (Figure 1).

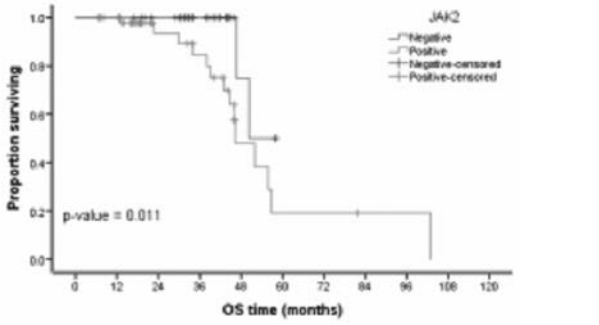

Figure 1.

Summary/Conclusions: MPN10 score is directly affected by JAK2 and CALR positivity and can be used as a major predictor of survival in MPNs patients. Triple negative ET patients in our cohort have significantly lower MPN10 score, show lower incidence of BM fibrosis and splenomegaly which may indicate a more indolent disease course.

Background: Interferon-alpha (IFNa) based therapies have been successfully used in myeloproliferative neoplasms for over thirty years. A known burden for long-term therapy applying IFNa in otherwise fit outpatients is the necessity of frequent hospital visits for product administration. Ropeginterferon alfa-2b (AOP2014) is a novel long-acting monopegylated IFNa allowing initially bi-weekly and, in long-term maintenance, monthly administration. To further improve on convenience and compliance, a pre-filled, dose-adjustable pen was developed for patient self-administration at home.
Aims: Open-label, single arm, multicenter phase III trial assessing the self-administration of AOP2014 using a pre-filled, dose-adjustable pen (NCT: 2014-001356-31).
Methods: The study was performed in 18 sites in 8 European countries. Patients were eligible who completed the AOP2014-arm in the PROUD-PV study (12 months of treatment). A total of 7 visits was scheduled within 3 months (two supervised self-administrations at site, followed by four self-administrations in the home-setting, and a final assessment visit at study site).
Results: A total of 36 patients were enrolled and received the AOP2014 pen for self-administration. The mean age was 58.5 years (range 37 to 77 years), 23/36 (63.9%) were male patients and a large proportion of patients (15/36 [41.7%]) entering the study received a baseline dose of 500 µg AOP2014. 72.2% (26/36) used 2 pens (dose >250 µg) and 27.8% of patients (10/36) used one pen (dose up to 250 µg) to administer the appropriate dose. At the first supervised visit, 80.6% (29/36) of patients had achieved full success, defined as no technical problems with the pen experienced by the patient during the injection, and no early withdrawal of the pen (before injection was complete), both observed by the investigator. At the second supervised visit the full success rate was 91.7% (33/36). The majority of observations resolved after the second supervised visit. Only 5 patients (13.9%) needed one additional supervised visit prior using the pen correctly in a home-setting. All patients had achieved full success at Visit P7 (supervised assessment visit at study end).
The patients responded favourably to the use of the pre-filled pen for the administration of AOP2014 and the accompanying instructions. Based on the Investigator's assessment, no patients exhibited any visible pain or physical discomfort, appeared to be dissatisfied when using the pen or exhibited any frustration using the pen, nor did the patient report any pain arising from the use of the pen. The majority of patients (32/36 patients) rated the instructions for the AOP2014 pen (*i.e.* scope and structure of the leaflet, clarity and comprehensibility of the text, clarity of the images and design of the leaflet), and the AOP2014 pen itself (*i.e.* setting the dose, user-friendliness, injection procedure) as "very good" or "good". The haematological parameters and spleen size remained stable throughout the study, and the rate of responders (haematological response with and without spleen size) was maintained during the entire study, suggesting that the use of the pen device did not affect drug activity. Of the 47 adverse events (AE) reported during the study, 19 were related. Most AEs were mild to moderate in intensity. One serious AE (mild atrial fibrillation, unrelated), one pen-related AE (mild nervousness reported prior first administration in the home setting), and one Grade 3 TEAE (pain in extremity, related) were recorded, but none led to a dose reduction.

Summary/Conclusions: The AOP2014 pen was well accepted and no major difficulties were reported. The study drug performed as expected and there were no safety concerns arising from the administration of AOP2014 using the pen device. The AOP2014 pen allows for individual dosing and a patient-convenient mode of self-administration of ropeginterferon alfa-2b at home and is expected to support adherence and compliance in the long-term treatment of PV patients.

PB2054

JAK2, CALR AND MPL MUTATIONS: CORRELATION WITH PHENOTIPE DISEASE AND HISTOPATHOLOGICAL FEATURES OF BONE BIOPSY

H. J. Campo Palacio[1,*], M.J. Ramírez Sánchez[1], A.M. Rodríguez Fernández[2], L. Hermosín Ramos[1], B. Bellosillo Paricio[3], E. Carrillo Cruz[4]
[1]Haematology, [2]Pathology, Jerez De La Frontera Hospital, Jerez De La Frontera, [3]Pathology, Hospital del Mar, Barcelona, [4]Haematology, Hospital Virgen del Rocío, Sevilla, Spain

Background: Drivers mutations JAK2, CALR and MPL are mutually exclusive in Essentials thrombocytemia (ET) and these are included in the diagnostic criteria of mieloproliferative neoplasms (MPNs). Consistent with know literature, the molecular characterisation have implications in the phenotipe disease and it might be interesting to study if these are associated with the histopathological characteristics of bone marrow biopsy
Aims: The purpose of this work is analyse the correlations between clinical-biological and histological characteristics of bone marrow biopsy and the mutational status (JAK2, CALR, MPL).
Methods: The study included 76 patients with ET diagnosed according to WHO criteria at the Haemathology Departament from Hospital de Jerez from January 2005 to December 2015. We examined the prevalence, and clinical and laboratory correlations of JAK2/CALR/MPL mutations. To evaluated the histology, one pathologist with expertise in haematopathology review the bone marrow biopsies corresponding to 44 patients with ET. We incluyed only bone marrow biopsies of at least 10 mm in length and/or minimun 8 inter-trabecular areas. The pathologist only had access to age and gender data. Mutations JAK, CALR and MPL were analysed by PCR real time and sanger sequencing.
Results: There where 55 (72%) patients JAK2, 12 (15.5%) patients CALR, one patient MPL and 9 (11.8%) patients triple-negative (TN). The main clinical and laboratory features of the patients are show in Table 1A. As can be seen, a 75% of patients belonged a high risk group, 18 (23%) patients presented thrombotic events before diagnosis and only 4 (5.3%) during the evolution. Clinical and molecular characteristics of patients as age, sex, hemoglobin level and stratification of risk were statistically significant. (Table 1A). Thromboembolics events seemed to be more frequent in patients with JAK2 mutation, although statistical significance was not achieved. The correlation between histopathological characteristics and mutational status are shown in Table 1B. We observed differences between the presence of laxes groups of megacaryocytes according with the mutational status and there were more frecuently in patients with CALR mutation (p= 0.01). With a median of follow up of 4 years (ranger 0.3-11 años) a total of 6 patients had died. Two patients evolved to overt, one of them to acute leukaemia and the other one to myelofibrosis at 66 and 44 months from ET diagnosis respectively.

Summary/Conclusions: In our study we can confirm that there are differences between clinical and laboratory finding according with mutational status, as shown in previus studies. The most consistent finding of this study was the presence of laxes groups of megacaryocytes significantly higher in those with CALR mutations. The major limitations of this study include a small number of patients and biopsies, available to analysed, this might be the mayor causes for the lack of the data demostrating clinical and histologycal relevance. But our results should not be underestimated because, to our knowledge, this is the second study thas has investigated this relation.

PB2055

CLINICAL IMPLICATION OF QUANTITATIVE JAK2 V617F ANALYSIS WITH DROPLET DIGITAL PCR IN MYELOPROLIFERATIVE NEOPLASMS

E. Lee[1,*], K. J. Lee[2], H. Park[2], J. Y. Chung[2], M.-N. Lee[3], M.H. Chang[4], J. Yoo[5], H. Lee[1], S.-Y. Kong[6], H.-S. Eom[1]
[1]Hematology, [2]National Cancer Center, Goyang, [3]Green Cross Laboratories, Yongin, [4]Oncology-Hematology, [5]Laboratory Medicine, National Health Insurance Service Ilsan Hospital, [6]Laboratory Medicine, National Cancer Center, Goyang, Korea, Republic Of

Background: JAK2 V617F is the most common genetic mutation in myeloproliferative neoplasms (MPN) and included in the major diagnostic criteria. Beyond the description of existence, quantification of mutational load is proposed as a useful information to classify subgroups of MPN and to predict prognosis. Droplet digital PCR (ddPCR) is a novel assay which has an advantage in accurate and reproducible quantitative analysis.
Aims: This study was planned to verify the correlation of ddPCR with pyrosequencing in diagnosis of MPN and to investigate clinical implication of the mutation burden in disease course.
Methods: Between 2012 and 2016, peripheral blood or bone marrow samples were obtained from 56 patients at diagnosis and every 3 months after enrollment. Inclusion criteria were 1) older than 20 years, 2) who were newly diagnosed with MPN and 3) diagnosed with MPN before, not met the indication of JAK2 inhibitor treatment yet. JAK2 V617F mutation was detected by pyrosequencing as diagnostic work-up. The ddPCR was performed using the same samples with pyrosequencing to prove correlations between assays and to establish a detection sensitivity cutoff. Clinical aspects and hematologic profiles of enrolled patients were reviewed.
Results: The lowest value of measured JAK2 V617F allele by ddPCR except negative samples in our study was 0.01%, which was approximately 0.07 copies/uL of mutant allele. Some discrepancies were observed from 0.0001% to 0.01% concentration between the expected and measured values in ddPCR detection sensitivity assay, 0.1% was determined as the cutoff. Forty-two patients (75%) were positive for JAK2 V617F by pyrosequencing and 46 (82.1%) were positive by ddPCR. The mean mutated allele at diagnosis was 37.5%±30.08%. With ddPCR, the mean was 40.7%±31.2%. Pyrosequencing and ddPCR were highly correlated (r=0.9712, P<0.001). JAK2 V617F burden measured with ddPCR was significantly different by subgroups (P<0.001). In comparison of one disorder with another, polycythemia vera (PV) had more amount of mutant allele than essential thrombocytosis (ET) (P=0.001), however, differences between PV-myelofibrosis (MF) and ET-MF were not statistically significant. Follow-up samples were available in 12 patients and 8 were JAK2 V617F positive. Among them, reduction of mutant burden after treatment was observed in 6 patients (75%). JAK2 V617F burden showed initial reduction in a MF patient treated with JAK2 inhibitor, however, after dose reduction for toxicities, the JAK2 V617F mutation increment with hematologic aggravation was discovered. Mutation burden decrease showed a tendency consistent with hematologic improvement.Hematologic characteristics and JAK2 V617F load at the initial diagnosis and follow-up after treatment (Table 1, Figure 1).

Table 1.

Pt. No	Sex/Age	Subgroup	Initial JAK2 V617F allele (%)	Follow-up JAK2 V617F allele (%)	Difference	Initial CBC (WBC-Hb-Plt)	Follow-up CBC (WBC-Hb-Plt)	Treatment

* Data from the first follow-up sample.
† Data from the next follow-up sample in the same patient.

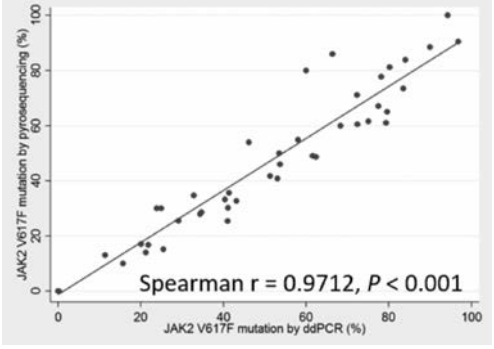

Figure 1.

Summary/Conclusions: Quantitative analysis of JAK2 mutation using ddPCR was highly correlated with pyrosequencing and might reflex clinical treatment response.

PB2056

CLINICAL IMPACT OF JAK2 AND CARLETICULIN GENE MUTATIONS ON PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

M. Napolitano[1,*], S. Siragusa[1], S. Mancuso[1], M. Santoro[1], V. Leone[2], C. Marino[2], F. Di Piazza[3], A. Russo[4], V. Accurso[1]
[1]UO Ematologia, University Of Palermo, Palermo, [2]Oncoematologia, ASP Local Hospital, Trapani, [3]Laboratorio di genetica e oncologia molecolare., [4]UO Oncologia, University Of Palermo, Palermo, Italy

Background: JAK2 (V617F) gene mutation is found in approximately 60% of patients with Essential Thrombocythemia (ET), while 5-10% of JAK2 (V617F) negative ET patients carry MPL gene mutations involving codon 515. Recently, mutations at the exon 9 of calreticulin (CALR) gene have been identified in approximately 50% of patients with ET, unmutated for Jak2 and MPL.
Aims: Primary aim of the current study was to analyze the prevalence of JAK2, MPL and CALR gene mutations in patients with ET; secondary aim was to evaluate the impact of gene mutations on clinical features of ET at diagnosis.
Methods: A cohort of consecutive patients with a diagnosis of ET followed between January 2013 and June 2016 were considered. JAK2 (V617F) gene mutation was detected by PCR testing; MPL and CALR mutations were analyzed by direct sequencing methods. Thrombotic risk score was calculated according to European Leukemia Net recommendations. Data were statistically analyzed.
Results: Overall**,** 148 patients were included: 107 (72, 30%) had JAK2 (V617F) gene mutation (JAK2+), 12 (8, 10%) carried a mutation at exon 9 of CALR gene (CALR+), 3 (2, 02%) carried a mutation at codon 515 of MPL gene, 26 (17.58%) patients were not mutated for JAK2, CALR and MPL genes (triple negative).CALR+ subjects, compared to JAK2+ patients, had a younger age at diagnosis: median 48 year (25-92) in CALR+ patients *vs* 72 years (18-93, respectively. Patients with MPL mutation had a median age of 82 years while triple negative subjects had a median age of 59 years (23-89). The mean score for thrombotic risk was 0 in CALR+ patients and 1 in JAK2+, MPL+ and triple negative patients. The distribution of International Prognostic Score for Essential Thrombocythemia (IPSET) categories was also statistically significantly different (p=0.003) for the three groups. The percentage of high-risk patients was 0 in CALR+ (0/12) group, 25, 60% (27/107) in JAK2+ group, and 18, 30% (5/26) in the triple negative group. The IPSETt model also stratified patients with statistically significant difference (p=0.001) among the three groups: the percentage of high-risk patients was 16, 66 (2/12) in the CALR+ group, 82, 35% (88/107) in the JAK2+ group, and 33, 33(9/29) in triple negative group. CALR+ patients belonged more frequently to the low /intermediate risk group than JAK2 +patients (80% *versus* 17, 5%, p=0.05). The incidence of thrombotic events at diagnosis of ET was 0 in the CALR+ group, 28,03% (30/107) in the JAK2+ group and 23,07% (6 /26) in the triple negative group. The median overall survival was not reached in any group.
Summary/Conclusions: CALR+ patients with ET are phenotypically distinct from JAK2+and triple negative patients. We can speculate a potential protective role of CALR mutation given the absence of thrombosis in IPSS and IPSETt high-risk patients.

PB2057

RUXOLITINIB IN MYELOFIBROSIS: A MULTICENTRE EXPERIENCE FROM THE EAST OF ENGLAND

J. Russell[1,*], D. Sparksman[2], A. Dicu[3], K. Maw[2], C. Gomez[2], M. Mangi[2], I. Whalley[4], A. Collins[3], S. Sadullah[2]
[1]Department of Haematology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, [2]James Paget University Hospital, Great Yarmouth, [3]Norfolk and Norwich University Hospital, Norwich, [4]Ipswich Hospital, Ipswich, United Kingdom

Background: Ruxolitinib, an oral Janus Kinase (JAK)1/JAK2 inhibitor, was approved in the EU in August 2012 for treating disease-related splenomegaly and constitutional symptoms in adults with primary myelofibrosis (PMF), post-polycythaemia vera myelofibrosis (PPV-MF), and post-essential thrombocythaemia myelofibrosis (PET-MF).
Aims: We present a retrospective multicentre analysis of MF patients treated with ruxolitinib from August 2012 to December 2016 at 3 centres in the East of England to assess its efficacy, safety, and tolerability in a 'real-world' clinical setting.
Methods: Retrospective data collection using electronic medical records and cancer registry data identified 49 MF patients treated with ruxolitinib at the James Paget, Norfolk and Norwich, and Ipswich hospitals (28, 14 and 7, respectively) over a 52-month period. Five had less than 3 months' follow-up and were excluded.
Results: The patient group was 61.4% male, with a median age of 71 years (41–91). There were 16 (36.4%) patients with PMF, 13 (29.5%) with PPV-MF, 9 (20.5%) with PET-MF, and 6 (13.6%) with post-myeloproliferative disorder (unclassified)-MF. The indication for treatment was painful splenomegaly in 20 (45.5%) patients, constitutional symptoms in 23 (52.3%), and portal hypertension in 1 (2.3%). Ruxolitinib was first-line therapy in 10 (22.7%) patients, second-line in 24 (54.5%), and third-line or greater in 10 (22.7%). Starting doses ranged from 5mg BD in 2 (4.6%), 10mg BD in 14 (31.8%), 15mg BD in 11 (25%) and 20mg BD in 17 (38.6%), with occasional dose reduction/interruption primarily due to thrombocytopaenia. Fifteen (34.1%) patients were IPSS 3+, 22 (50%) IPSS 2, 6 (13.6%) IPSS 1, and 1 (2.3%) IPSS 0. Mutation analysis was available for 32 (72.7%) patients, of which 29 (90.6%) were JAK2 V617F-mutated, 2 (6.3%) were JAK2 V617F/exon 12-unmutated, and 1 (3.1%) was CALR-mutated. The median duration of treatment was 16.4 months (3–45) and median time to progression was 15.5 months (7–32). Progression-free survival (PFS) was 65.9% and overall survival (OS) 68.2%. Seven patients died from AML, 5 from progressive MF, and 2 from pneumonia. Multivariate analysis showed that 'advancing age' and 'excess peripheral blasts (≥1%)' were predictive of poor outcomes (HR 1.08, 95% CI 1.01-1.16; p=0.024 and HR 4.38, 95% CI 1.12-17.09; p=0.033, respectively). Clinical assessment of spleen size was available for 29 (65.9%) patients and showed a reduction in splenomegaly in 16 (55.2%), an increase in 8 (27.6%) and no change in 5 (17.2%). Weight gain occurred in 32 (72.7%) and demonstrated a strong survival advantage (HR 0.21, 95% CI 0.07-0.65; p=0.006). The most common haematologic adverse events (AEs) were cytopaenias. Forty patients (90.9%) had anaemia and 22 (50%) were transfusion-dependent, compared with 29 (65.9%) and 10 (22.7%) pre-treatment, respectively. Thirteen (29.5%) patients also received an erythropoiesis-stimulating agent. Thirty-one (70.5%) patients had thrombocytopaenia (6.8% grade 4) compared with 13 (29.5%) pre-treatment. The most frequent non-haematologic AEs were minor infections, documented in 17 patients (38.6%), and included lower respiratory tract infections, candidiasis, and HSV/VZV reactivation. One patient died from Aspergillus pneumonia. Twenty-nine patients (65.9%) remain on treatment.
Summary/Conclusions: Ruxolitinib was well-tolerated and effective in improving constitutional symptoms in our 'real-world' study population. Therapeutic response and safety profile was similar to trial data although we observed a higher incidence of minor haematologic AEs that were readily managed with supportive care. Weight gain was associated with a strong survival advantage and could prove a useful clinical marker of response. The majority of patients remain on active treatment.

PB2058

MONITORING OF TRANSIENT MYELOPROLIFERATIVE DISORDER AND LEUKEMIA IN DOWN'S SYNDROME : A SINGLE UNIVERSITY HOSPITAL STUDY

J.E. Park[1,*], I. Hwang[1]
[1]Pediatrics, AJOU University School of Medicine, Suwon, Korea, Republic Of

Background: Children with Down syndrome (DS) have a 10- to 20-fold increased risk of developing leukemia. But some patients don't suffer leukemia even they have significant numbers of blast cell in their peripheral blood. These condition called Transient myeloproliferative disoder(TMD), and it is a disease entity unique to DS newborns and is defined as the morphologic detection of blasts in DS less than three months of age.
Aims: This study gathered DS patients to find some difference between leukemia and TMD, to determine prognosis and risk factors.
Methods: We collect 317 patient's blood lab results in 433 DS patients. 102 patients has leukocytosis, and in 18 case found blast cells in their peripheral blood.
Results: 12 patients have found blast in three months of life, 11 of them finally diagnosed to TMD, and only 1 patient progress to Acute Myeloid Leukemia(AML) in 98 days of his life. Other 6 patients have blast in their blood after three months of life, and underwent chemotherapy due to hematologic malignancy. All patients with leukemia has anemia at diagnosis, which is not found in TMD patients*(p=0.018)*. In 7 Leukemia patients, 3 was acute Lymphoblastic Leukemia(ALL), 4 was AML. All AML patients has clonal change additional to trisomy 21 at their diagnostic point, which didn't found at TMD and ALL patients, even it didn't confirm former examination.
Summary/Conclusions: DS Patient who has blast in their peripheral blood before 3 months of life need closely follow up their Complete Blood Count and Chromosome analysis to find whether TMD progress to leukemia.

PB2059

INFECTIOUS EVENTS IN A COHORT OF PATIENTS WITH MYELOFIBROSIS UNDER TREATMENT COMPARING RUXOLITINIB WITH CONVENTIONAL THERAPY. A MONOCENTRIC EXPERIENCE OF 22 PATIENTS RETROSPECTIVELY ANALYSED

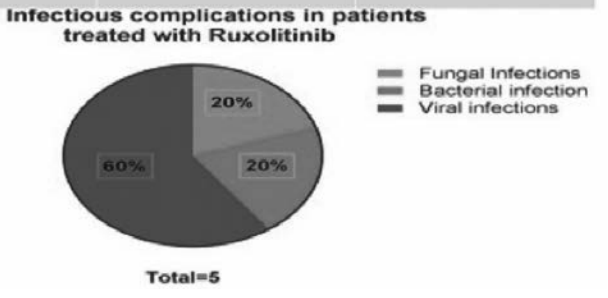
L. Torti[1,*], A. Morelli[1], F. Bacci[2], P. Di Bartolomeo[1]
[1]Department of Hematology and Bone Marrow Unit , Pescara, [2]Section of Hematopathology, Department of Hematology and Oncological Sciences, S. Orsola-Malpighi Hospital, Bologna, Italy

Background: Treatment with the Janus-activated kinase (JAK) 1 and 2 inhibitor ruxolitinib decreases constitutional symptoms and spleen size in myelofibrosis. However accumulating evidences suggest that the drug also exerts substantial immunosuppressive activity. The impressive clinical activity of ruxolitinib is predominatly mediated by its profound anti-inflammatory effects modulating dendritic cell (DC) function resulting in impaired CD4+ and CD8+ activity. Several studies have shown that Ruxolitinib affects different cytokines (IL1, IL6 and TNFalfa) and other immune processes and has been linked to increased incidence of opportunistic and no opportunistic infections. Herein we report our experience at our Centre.
Aims: In our retrospective study we analysed myelofibrosis patients treated with Ruxolitinib and cytoreductive treatment with Hydroxiurea and supportive therapy followed in our Department from 2012 to 2016 to evaluate rate of infections developed.
Methods: We reviewed 22 patients presenting myelofibrosis (median age 72, range 60-86)describing clinical and biological features (Table 1). Our aim was description of documented infections identified with conventional treatment and with Ruxolitinib. They were 11 treated with JAK inhibitors and 11 with Hydroxiurea taken orally, similar for age and clinical features.
Results: A total of 22 patients consecutively diagnosed were included in this analysis. There were 15 primary and 7 secondary myelofibrosis patients. According to the Dynamic International Prognostic Scoring System (DIPSS) 8 were low risk, 10 were intermediate risk and 4 were high. A total of 5 documented infections were identified throughtout the evaluation period, 4 were grade 1 and one grade 2. They are various including oral herpes simplex reactivation, pneumonia, recurrent viral flu syndromes, esophagitis fungal and urinary infections. All of them were present in the subgroup of patients undergoing therapy with Ruxolitinib (45%) after a medium time of 8 months from beginning of therapy (range 3-10). No patients received any anti-infective prophylaxis.
Median total daily dose of ruxolitinib was 10 mg (range 5-20). All of this infectious complications resolved after antimicrobial therapy and did not require hospitalization. None of patients were treated with concomitant immunosuppressive therapy. 3 of this patients presented renal impairment (median cratinine clearance of 46 ml/min).

Table 1.

CLINICAL AND BIOLOGICAL FEATURES OF PATIENTS REVIEWED

Characteristics	Group treated with Ruxolitinib	Group treated with conventional therapy
Gender M/F	8/34	29/13
Median age in years (range)	72 (60-86)	69 (51-88)
Number	11	11
Kind of disease	Primary Myelofibrosis (7), secondary Myelofibrosis (4)	Primary myelofibrosis (8), Secondary myelofibrosis (3)
JAK2V617F mutation	Positive (8), Negative (3)	Positive (6), Negative (5)
MPL mutation	None	1 (W515P)
DIPSS score	Intermediate -2 (7), High (4)	Low (8), Intermediate -1 (3)
Allelic Jak2V617F burden	45%, 65%, 99%, 38%, 88%, 79%, 82%, 65%	32%, 43%, 65%, 87%, 77%, 69%
Antiinfective prophylaxis	None	None
Cytogenetic evaluation	Deletion of chromosome 11 in one patient, rest are normal.	Deletion of chromosome 20 in one patient, rest are normal.
Renal impairment	5 patients	4 patients
Systemic symptoms	Present (11)	Present (7)
ECOG performance status 0-2	0-2 (8 patients), >2 (3)	0-2 (11 patients), >2 (0)



Summary/Conclusions: These data in our small series of patients suggest a higher incidence of ruxolitinib associated infections observed in clinical practice compared to traditional treatment. Immunosuppressive effect of Ruxolitinib is reported and the use of this drug in the transplant setting with beneficial effects on alloreactivity and on graft *versus* host disease is becoming more common. These patients might benefit from receiving prophylactic therapy with antiviral drugs or antibiotics or antifungal therapy or in alternative by careful monitoring. Finally nowadays physicians and patients should be aware of potential risks of using ruxolitinib including the risk of infections.
In summary, infections can occur in patients treated with ruxolitinib but are generally mild. Generally infections were non-life threatening and managed with appropriate supportive care.
Special care probably should be taken for patients older (more than 75 years old), treated with corticosteroid therapy and with renal impairment.
However larger studies are needed to confirm these observations.

PB2060

THE JAK2V617F MUTATION AND LEUKOCYTOSIS AS RISK FACTORS FOR INCIDENCE OF THROMBOTIC COMPLICATIONS IN PATIENTS WITH POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA

E. Simonovic[1,*], V. Colic[1]
[1]Internal Medicine, General Hospital Leskovac, Leskovac, Serbia

Background: Polycythemia vera (PV) is a clonal, chronic, progressive myeloproliferative disease, caused by transformation of pluripotent hematopoietic stem cell. It is a malignant hematological disease that leads to excessive proliferation of erythroid, myeloid and megakaryocytic elements in the bone marrow. Essential thrombocythemia (ET) is a clonal disorder of unknown etiology that affects multipotent hematopoietic stem cell, and it is characterized by enhanced formation of megakaryocytes in the bone marrow and for no apparent cause, by markedly increased platelet counts in peripheral blood. PV and ET belong to a group of Philadelphia chromosome negative myeloproliferative neoplasms. Thrombotic and hemorrhagic complications are the most common cause of morbidity and mortality in patients with PV and ET. It is thought that the *mechanisms* that *lead* to *thrombosis* in *MPN* are the following: *increased blood cell mass, abnormal platelet function* and the *phenomenon* of *spontaneous aggregation*. The contribution to the incidence of thrombosis: increased level of products that are formed in the activation of platelets (thromboxane, p-selectin); increased production of microparticles that are parts of various cell membrane structures of platelet origin; JAK2V617F mutation. In patients with MPN there is increased activity of the coagulation system due to the resistance to the anticoagulant function of thrombomodulin.
Aims: The aim of this study is to monitor JAK2V617F mutations and *leukocytoses* as potential risk factors for the development of thrombotic complications in patients with polycythemia vera and essential thrombocythemia.
Methods: During the five-year period we monitored the occurrence of thrombotic complications in 56 patients (of both sexes, aged between 30 and 78 years), being diagnosed with PV and 22 patients (of both sexes, aged between 38 and 79 years) being diagnosed with ET. We used methods of clinical, laboratory, ultrasound and CT scans. With regard to the risk factors we followed the presence of JAK2V617F mutations and *leukocytoses.*
Results: Leucocyte count ranged from 5,2-27,1 x 10^9/L. The highest leucocyte count was recorded in the group of patients with PV ($p<0,01$). JAK2V617F mutation was also statistically more significantly present in patients with PV. The highest percentage of thrombotic complications (arterial and venous) was found in the group of patients with ET, which was statistically more significant relative to PV. Thrombotic complications in those groups were more frequent in percentage with patients diagnosed with leukocytosis, but statistical significance was present only in the group with PV. Thrombotic complications were in both groups more frequent in percentage with JAK2V617F positive patients, but without statistical significance. It is believed that activated neutrophils bind to platelets by influencing the increased expression of tissue factor activity, as well as the activation and damage of the endothelial cells, especially with JAK2V617F positive patients.
Summary/Conclusions: Leukocytosis and JAK2V617F may be considered as potential risk factors for the incidence of thrombosis in patients with PV and ET. Further follow-up of those patients, as well as a larger number of subjects are needed.

PB2061

RISK FACTORS FOR INCIDENCE OF HEMORRHAGIC COMPLICATIONS IN PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

E. Simonovic[1,*], L. Macukanovic-Golubovic[2]
[1]Internal Medicine, General Hospital Leskovac, Leskovac, [2]Internal Medicine, Clinic of Hematology, Niš, Serbia

Background: Myeloproliferative neoplasms (MPN) are the group of clonal, malignant hematopoietic stem cell disorders, characterized by the proliferation of one or more blood lines with normal or nearly normal maturing in the bone marrow and in extramedullar hematopoietic organs. Hemorrhagic syndrome is a complication that occurs in about a quarter of patients with PV and even 60% of patients with ET. Bleeding may complicate the clinical course of the IMF. It is manifested in the form of petechiae and ecchymoses, or may be life-threatening as uncontrolled esophageal bleeding. Bleeding occurs due to ineffective megakaryocytopoiesis, retention of platelets in the large spleen, qualitative

platelet disorders, acquired deficiency of factors V and vWF, disseminated intravascular coagulation.
Aims: The aim of this study is to monitor the count of erythrocytes, leukocytes and platelets, as well as hemoglobin and hematocrit values as potential risk factors for the incidence of hemorrhagic complications in patients with chronic myeloproliferative neoplasms.
Methods: During the three-year period we monitored the occurrence of hemorrhagic complications in 139 patients of both sexes, aged between 30 and 87 years, being diagnosed with Ph-myeloproliferative neoplasm. Patients were classified into the following groups: 1. Group with polycythemia vera (PV) (61); 2. Group with essential thrombocythemia (ET) (28); 3. Group with idiopathic myelofibrosis (IMF) (25); 4. Group with unclassified myeloproliferative neoplasm (MPNs) (25). The following possible risk factors were monitored: counts of erythrocytes, leukocytes and platelets, as well as hemoglobin and hematocrit values. We used methods of clinical, laboratory, endoscopy, ultrasound and CT scans.
Results: The highest percentage of hemorrhagic complications were in the group of patients with ET and IMF (p<0,01), followed by the group with MPNs (p<0,05). In all three groups, the incidence of hemorrhagic complications in patients older than 65 years of age was higher (p<0,001). The erythrocyte count ranged from 6,45-8,89 x 10^{12}/, leukocyte count 1,2-27,1 x 10^9/L and the platelet count ranged from 10,2 -1986,5 x 10^9/L. Hemoglobin values ranged from 176-210 g/L, and hematocrit from 0.58 to 0.83 L/L. The highest erythrocyte count, the highest hemoglobin and hematocrit values, as well as the highest leukocyte count was recorded in the group of patients with PV and MPNs (p <0,001) and the lowest in the group of patients with IMF (p <0,01). Among the group of patients with ET and MPNs there was no statistically significant difference in those parameters. In the group of patients with PV and MPNs hemorrhagic complications were more frequent in percentage in patients with leukocytosis and erythrocytosis, but without statistical significance. The highest platelet count was found in the group of patients with ET and MPNs (p<0,001), and the lowest in the group of patients with IMF (p<0,01). Among the group of patients with PV and MPNs there was no statistically significant difference with regard to platelet count. Hemorrhagic complications were more frequent both in patients with platelet count below 10x10^9/L (p<0,05) and in patients with platelet count over 1000x10^9/L (p<0,01). The increase in platelet count influences the adsorption of larger von Willebrand multimers on the platelet membrane, thus having an effect on their elimination from circulation and degradation.
Summary/Conclusions: The platelet count can be considered a significant parameter for monitoring the risk of hemorrhagic complications in patients with myeloproliferative neoplasms, particularly with ET and IMF. Deviation from the count of leukocytes, erythrocytes, hemoglobin and hematocrit values may be considered as a potential risk factor for bleeding in patients with myeloproliferative neoplasms, but further follow-up and a larger number of subjects are needed. The age of the patient can also be considered as a risk factor for the incidence of hemorrhagic syndrome in those patients. The follow-up of patients with unclassified myeloproliferative neoplasms has been particularly important, which showed a high prevalence of hemorrhagic complications, and with the purpose of their further differentiation.

PB2062

CLINICAL RELEVANCE OF JAK2V617F MUTATIONAL LOAD IN PATIENTS WITH PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS FROM REPUBLIC OF MACEDONIA (SINGLE-CENTER EXPERIENCE)
M. Popova-Labachevska[1,*], L. Cevreska[1], A. Dimovski[1], M. Ivanovski[1], D. Dukovski[1], B. Kocoski[1], A. Eftimov[1], S. Trajkova[1], I. Panovska-Stavridis[1]
[1]Hematology, University Clinic of Hematology, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Polycythemia vera (PV), essential thrombocytosis (ET, and primary myelofibrosis (PMF) are Philadelphia chromosome negative myeloproliferative neoplasms (MPN) characterized by the expression of an aquired activated JAK2V617F mutation. Up to date, it remains controversial how one mutation can lead to expression of three different clinical MPN phenotypes. However, several studies have shown that the JAK2V617F allele burden may correlate with specific MPN entity.
Aims: In order to further clarify these observations, we evaluated the JAK2 mutational status and its clinical implications in 233 JAK2 V617F+patients with different MPNs from the Republic of Macedonia.
Methods: We conducted a single center retrospective study which included 233 patients with JAK2V617F+MNP diagnosed according to WHO criteria, with median follow up period of 4 years. Quantification of the JAK2V617F mutation was analized with the Real Time PCR method using the Larsen protocol. Based on the mutational load patients were divided in three groups: first with <10% mutational load, second with 10-50% load and third with >50% mutational load. The correation of the allele burden with various clinical parameters was done by Mann-Whitney and student's tests using Statgraphics 4.3 software.
Results: Our study showe that median allele burden was lowest in patients with ET (22.8%), followe by PV patients (37.1%) and PMF pts (49.6%) (p<0.01). A higher mutation burden (>50% *vs* <10%) was associated with advanced age (67.5 *vs* 58,5 years and 65 *vs* 58 years in ET and PMF pts respectively), with higher leucocyte count (10^3 /µL) (9,87 *vs* 8,87, 13.8 *vs* 12.4, and 18.99 *vs* 14,8 in ET, PV and PMF pts respectively), with elevated erytrocyte count (5.76 *vs* 4.85 and 5.59 *vs* 4.52 in ET and PMF pts respectively), and with higher hemoglobin level (g/dL) and platelet count 10^3 /µL (15.45 *vs* 14.35 and 1071.5 *vs* 860.5 in ET patients respectively) (p<0.05 for all comaprisions)
Summary/Conclusions: Our study confirmed that higher allele burden is associated with advanced age, polycythemic features, and increased leucocytes and platelets counts regardless of the diagnosed MPN entity and suggests that implementation of JAK2V617F allele burden in the diagnostic workup of MPN pts could help for choosing the optimal treatment option in this group of patients.

PB2063

CSF3R T618-MUTATED CHRONIC NEUTROPHILIC LEUKEMIA: A RARE CASE SUCCESSFULLY TREATED WITH RUXOLITINIB
V. Calafiore[1], M. Parisi[1], V. Zammit[1], E. Martino[1], M. C. Pirosa[1], A. Spitaleri[1], F. Stagno[1], C. Conticello[1,*], F. Di Raimondo[1]
[1]Division of Hematology, A.O. "Policlinico-Vittorio Emanuele", University of Catania, Via Citelli 6, 95124 Catania, Italy, Catania, Italy

Background: Chronic neutrophilic leukemia (CNL) is a rare BCR-ABL1–negative myeloproliferative neoplasm (MPN) with only 200 patients reported to date according to the WHO criteria. These cases are characterized by a high number of mature neutrophils in peripheral blood (PB), a hypercellular bone marrow due to neutrophilic granulocyte proliferation and hepatosplenomegaly. None standard of care exist for CNL; most patients are palliated with hydroxyurea, interferons, splenic radiation or splenectomy.
In the past years CNL has been often confused with chronic myeloid leukemia (CML), atypical CML (aCML) or chronic myelomonocytic leukemia (CMML), however, this diagnosis has been more defined since the oncogenic mutations in the granulocyte colony-stimulating 3 factor receptor (CSF3R) gene were identified in approximately 83% of WHO-defined CNL patients.
CSF3R T618I mutation is now considered as a highly specific molecular marker for CNL that is sensitive to *in vitro* and *in vivo* inhibition by currently approved protein kinase inhibitors.
Aims: here we report a case of a 76-years old man with diagnosis of chronic neutrophilic leukemia, according to WHO criteria, successfully treated with ruxolitinib.
Methods: On May 2015 a 76 aged male patient presented at our Institution with fatigue, night sweats, neutrophilic leukocytosis (neutrophils 42.080/mmc, immature granulocytes <5%), and symptomatic splenomegaly (277x127x200 mm). Marrow biopsy was hypercellular (100%) with myeloid hyperplasia, mild myeloid dysplasia and profound erythropoietic hypoplasia; reticulin fibrosis was minimally present. Molecular profiling demonstrated no mutations of JAK2 or CALR and polymerase chain reaction (PCR) studies for t(9; 22) and BCR-ABL fusion, was negative.
The patient was initially treated with hydroxyurea with a provisional diagnosis of prefibrotic phase of primary myelofibrosis (PMF), but symptoms worsened and the therapy was interrupted after 9 months for progressive anemia (Hb 9,9 gr/dl) and thrombocytopenia (82.000/mmc); meanwhile polymerase chain reaction (PCR) studies revealed the presence of CSF3R T618I mutation, suggesting diagnosis of CNL. By taking into account the activity of ruxolitinib in overt PMF, we decided to start this drug. The initial dose was 5 mg twice daily with a gradual increase in the dose to 20 mg twice daily when platelet count became normal.
Results: on a follow-up of 6 months after initiation of ruxolitinib therapy, symptoms resolved, hemoglobin and platelet levels improved (PLT 186.000/mmc), leukocytosis persisted (WBC 24.600/mmc), and the patient achieved a dramatic reduction in spleen size (209x119x74 mm).
Summary/Conclusions: Current data suggest that constitutively active JAK-STAT signaling plays a central role in the pathogenesis of BCR-ABL1 –negative myeloproliferative neoplasms (MPNs); our experience suggests that ruxolitinib use in CNL patients can induce partial responses by improving marrow function (normalization of hemoglobin and platelets count), splenomegaly and symptoms.

PERIPHERAL BLOOD CELL STUDY FROM PATIENTS WITH FOLLICULAR LYMPHOMA AND DIFFUSE LARGE B-CELL LYMPHOMA: WHAT SHOULD WE EXPECT?

D. Subirá[1,*], H. Guillén[1], C. Fernández Maqueda[2], Á. Gil[1], D. de Miguel[1], N. Golbano[1], F. Barriopedro[1], M. Morales[1], M. Diaz Morfa[1], J. Arbeteta[1], A. Vázquez[1], S. Herrero[1]
[1]Haematology, Hospital Universitario de Guadalajara, Guadalajara, [2]Haematology, Hospital Universitario Puerta de Hierro, Madrid, Spain

Background: Follicular lymphoma (FL) may evolve to diffuse large B-cell lymphoma (DLBCL) and interactions between neoplastic cells and immune tumour microenvironment have been involved in this process. However, the potential value of the peripheral blood study to identify FL patients at high risk of progression is less known.
Aims: To describe the peripheral blood findings of patients with FL and DLBCL at diagnosis, and to investigate whether a particular lymphoid distribution could be associated with aggressive disease.
Methods: The study (performed between September 2012 and January 2017) included 52 patients (50% female) with a median age of 70.5 years (71% >60 years). Patients were newly diagnosed with *in situ* FL (n=1), Grade 1,2 FL (n=12), Grade 3 FL (n=11), and DLBCL not otherwise specified (n=28). *In situ* FL and Grade 1,2 FL were grouped as low-grade FL. Most patients with FL (11/13 low-grade FL and 8/11 Grade 3 FL) had clinical stages III/IV. Patients with primary or secondary immunodeficiency and those who had already received corticosteroids or chemotherapy were excluded from this study. A whole blood sample was studied at diagnosis of lymphoma and prior to the start of therapy, using multicolour flow cytometry immunophenotyping and a standard stain-lyse-wash protocol. A single monoclonal antibody panel including reagents against CD19, CD20, CD22, kappa, lambda, CD3, CD4, CD8, CD56 and CD45 was used, and a minimum of 300,000 events were acquired on the flow cytometer. Results were expressed as the absolute number/ml of monocytes, lymphocytes, T cells, CD4, CD8 and NK cells. Polyclonal and monoclonal B lymphocytes were also identified.
Results: No difference in the distribution by sex or age was found between patients with FL and DLBCL. A low cell count in at least, one lymphocyte population was detected in 35/52 patients (67.3%); 100% of cases had a low number of polyclonal B cells (<100/ml).Comparison of low-grade FL, grade 3 FL and DLBCL did not show any statistically significant difference regarding monocytes, CD4, CD8 and total T cells. Low-grade FL and DLBCL showed the highest number of differences, involving lymphocytes (2571±2439 *versus* 1495±671, p=0.001), NK cells (381±312 *versus* 204±167, p=0.03), the CD4:CD8 ratio (1.54±0.49 *versus* 2.06±1.44, p=0.002), and circulating monoclonal B cells, for both percentage (15.2±23.23 *versus* 1.94±5.23, p<0.001) and absolute number (869±1758 *versus* 18.75±46.47, p<0.001). Grade 3 FL and DLBCL also showed a different CD4:CD8 ratio (1.16±0.45 *versus* 2.06±1.44, p=0.001), with a trend toward significance regarding CD4 T cells (413±184 *versus* 685±457, p=0.077). Grade 3 FL had a lower number of polyclonal B cells as compared to DLBCL (66±41 *versus* 105±102, p=0.048). The peripheral expression of monoclonal B cells was higher in low-grade FL than in grade 3 FL, in both percentage (15.2±23.23 *versus* 4.58±8.48, p=0.008) and number (869±1758 *versus* 43.36±69.91, p=0.002) of monoclonal B cells. The number of lymphocyte subpopulations (≤1 *versus* ≥2) with low-cell counts was higher in grade 3 FL than in low-grade FL (p=0.03).
Summary/Conclusions: The peripheral lymphocyte profile in patients with FL and DLBCL is heterogeneous, but B-lymphopenia and CD4:CD8 ratio deviations are frequent findings. Regardless of clinical stage, low-grade FL had more circulating lymphoma cells and preserved lymphocyte populations than grade 3 FL. Further studies are warranted to confirm these exploratory findings and determine their clinical implications.

PB2065

POTENTIALITY OF PDPK1 AS A THERAPEUTIC TARGET MOLECULE IN MANTLE CELL LYMPHOMA

S. Maegawa[1,*], S. Tatekawa[1], Y. Chinen[1], T. Tsukamoto[1], K. Tanba[1], Y. Kimoto-Matsumura[1], T. Takimoto[1], Y. Mizuno[1], Y. Shimura[1], T. Kobayashi[1], S. Horiike[1], M. Taniwaki[1], J. Kuroda[1]
[1]Hematology, Kyoto prefectural university of medicine, Kyoto, Japan

Background: The deregulated activation of a Ser/Thr kinase 3-phosphoinositide-dependent protein kinase 1 (PDPK1) has been shown to promote the disease progression in various solid cancers. In hematologic malignancies, we have recently identified that the constitutive activation of PDPK1 and its downstream kinase RSK2 (PDPK1/RSK2 signaling axis) plays pivotal roles in multiple myeloma (MM) pathophysiology by promoting myeloma cell survival and proliferation (Chinen Y, Cancer Res 2014; Shimura Y, Mol Cancer Ther 2012). Mantle cell lymphoma (MCL) is cytogenetically and molecularly characterized by chromosomal translocation t(11;14)(q13;q32) for deregulated cyclin D1 (CCND1) overexpression, and has remained as one of hard-to-treat subtypes of non-Hodgkin lymphomas (NHLs).
Aims: The development of novel therapeutics for MCL has been urgently needed, therefore, this study investigated the potency of PDPK1 as a therapeutic target molecule in MCL cells.
Methods: Four MCL-derived cell lines (MINO, Jeko-1, JVM-2 and Z138 cells), three diffuse large B-cell lymphoma (DLBCL)-derived cell lines (KPUM-MS3, KPUM-UH1 and A3/KAW cells) and a Burkitt lymphoma (BL)-derived cell line (Namalwa) were utilized in this study. Patient-derived biopsied specimens were obtained with informed consent and subjected to the immunohistochemical (IHC) staining of phospho (p-) PDPK1^{Ser241}. Cell proliferation was assessed by a modified MTT assay. Antibodies utilized for Western blotting was performed for evaluating protein expression levels of PDPK1, p-PDPK1^{Ser241}, p-RSK2^{Ser227}, and RSK2. BX-912, a specific inhibitor for PDPK1, was purchased from Selleckchem (USA). RNA interference of PDPK1 was performed by transfecting short hairpin RNA plasmids into MCL cell lines by means of nucleofection (Lonza, Switzerland). This study was approved by the institutional review board of our institute.
Results: By means of IHC examination, our study revealed that PDPK1 was activated through phosphorylation in tumor cells of all 7 MCL patient-derived specimens examined, and this was also the case in all 5 DLBCLs examined and in all 5 follicular lymphomas examined. These indicated that PDPK1 is generally active in various types of B-cell lymphoid neoplasms. The *in vitro* treatment with BX-912 for 48 hours resulted in the dose-dependent inhibition of cell proliferation in all four MCL cell lines (IC_{50} 0.9~2.5 mM), and this inhibitory effect of BX-912 was more profound in MCL cell lines compared with three DLBCL cell lines (IC_{50} 3.7~17.0 mM) and a BL cell line (IC_{50} 2.9 mM). In addition, the flow cytometric analysis revealed that the growth inhibition of MCL cells by PDPK1 blockade with BX-912 was at least partly mediated through the induction of apoptosis. As the molecular sequelae, PDPK1 blockade by BX-912 resulted in dephosphorylation of RSK2-NTKD, while AKT activity or CCND1 expression was unaltered by BX-912 treatment in MCL cells. By gene knockdown of PDPK1 by RNA interference using three different short hairpin RNAs, we further validated that the reduction of PDPK1 protein caused the inactivation of RSK2 and the growth inhibition in MCL cell lines. Finally, when combined with various agents those are utilized for the treatment of MCL, such as doxorubicin, etoposide, fludaraibine, bortezomib, or ABT263, BX-192 showed additive/synergistic growth inhibitory effects in MCL cell lines.
Summary/Conclusions: Collectively, our study suggested that PDPK1/RSK2 signaling axis is the potential therapeutic target in MCL.

PB2066

THE ACQUISITION OF RESISTANCE TO BENDAMUSTINE HYDROCHLORIDE INDUCES MULTIDRUG RESISTANCE IN A NOVEL MANTLE CELL LYMPHOMA-DERIVED CELL LINE KPUM-YY1

T. Takimoto[1,*], H. Nagoshi[1], S. Maegawa[1], S. Tatekawa[1], T. Tsukamoto[1], Y. Chinen[1], Y. Shimura[1], M. Yamamoto-Sugitani[1], T. Kobayashi[1], T. Taki[1], S. Horiike[1], M. Taniwaki[1], J. Kuroda[1]
[1]Kyoto prefectural university of medicine, kyoto, Japan

Background: Bendamustine hydrochloride (BH) has been one of the most promising genotoxic moieties for mantle cell lymphoma (MCL), however, its mechanisms of action and the mechanisms for the acquisition of resistance to BH have not been fully clarified.
Aims: We tried to identify the underlying mechanisms for BH resistance to develop the strategy to overcome BH resistance.
Methods: This study was conducted in accordance with the Declaration of Helsinki and with the approval of the Institutional Review Board. Patient's sample was obtained along with the written informed consent. We firstly established a novel MCL-derived cell line, KPUM-YY1, from circulating lymphoma cells of a 77-year-old male patient with MCL. A BH-resistant subline of KPUM-YY1 (KPUM-YY1R) was established by continuous exposure to BH with gradual escalation of its concentration from 5 μM up to 50 μM for about 8 months. Cytogenetic analysis was performed by double color-fluorescence *in situ* hybridization and spectral karyotyping (SKY). The comparative gene expression profile (GEP) and the ingenuity canonical signal pathway analyses between of KPUM-YY1 and KUPM-YY1R were performed to identify the differential gene expression pattern along with the acquisition of BH resistance. Cell viability was evaluated by a modified MTT assay.
Results: SKY analysis revealed that both primary tumor cells and KPUM-YY1 had complex karyotype including three-way translocation t(8;14;11)(q24;q32;q13), involving the rearrangement of *cyclin D1*. The growth inhibitory IC_{50} to BH was 20 μM in KPUM-YY1 cells, while the cell proliferation was not inhibited by up to 60 μM of BH in KPUM-YY1R cells. When compared with the parental KPUM-YY1 cells, KPUM-YY1R cells showed the partial cross-resistance against doxorubicin, mafosfamide, melphalan, and vincristine. By GEP analyses, total of 472 genes were differentially expressed in KPUM-YY1R compared with KPUM-YY1 cells, including 312 upregulated more than 1.5-folds and 160 downregulated less than 0.67-folds in KPUM-YY1R cells. The ingenuity canonical signal pathway analysis based on the GEP results sug-

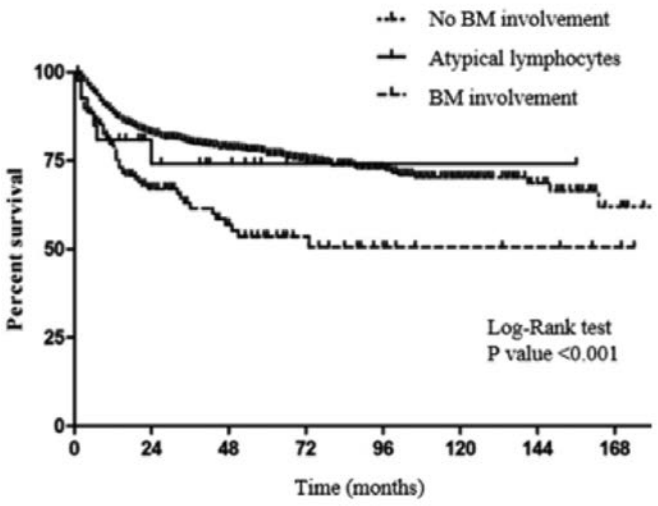
gested that KPUM-YY1R cells harbored the distinct gene expression patterns in *MDR1,* a gene for p-glycoprotein (P-gp) of drug transporter molecule, *MGST1*, a member of glutathione S-transferase (GST) families, and argininosuccinate synthetase 1 (*ASS1*), a rate-limiting enzyme for arginine biosynthesis. The upregulation of MDR1 (P-gp) and MGST1 were confirmed by Western blot or RT-PCR analysis in KPUM-YY1R compared with KPUM-YY1. Importantly, the addition of P-gp inhibitors, such as cyclosporine A, or GST inhibitors, such as ethacrynic acid, at least partly restored the sensitivity to BH in KPUM-YY1R cells, indicating the functional significance of the upregulation of MDR1 and MGST1 in the development of BH resistance in MCL. In addition, BH-resistance cells were also found to express decreased mRNA level of ASS1 which has been reported to play tumor suppressor roles and its loss has been associated with clinical aggressiveness in various cancers.
Summary/Conclusions: This study revealed that the multiple molecular mechanisms overlappingly underlie the development of BH resistance, therefore, the acquisition of BH resistance potentially leads multidrug resistance in MCL cells. The newly developed KPUM-YY1 cells and KPUM-YY1R cells deserve the identification of multiplex mechanisms underlying BH activity/resistance and the future development of strategy which overcomes the treatment refractoriness in MCL.

PB2067

COMPARISON OF OVERALL SURVIVAL ACCORDING TO BONE MARROW ASPIRATION RESULTS IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA

J.Y. Choi[1,*], K.-W. Kang[1], J.H. Kim[1], D.S. Kim[1], E.S. Yu[1], S.R. Lee[1], H.J. Sung[2], S.J. Kim[2], C.W. Choi[1], B.S. Kim[1], Y. Park[1]
[1]Division of Hematology and Oncology, Korea University School of Medicine, [2]Division of Hematology and Oncology, Samsung Medical Center, Seoul, Korea, Republic Of

Background: Bone marrow (BM) biopsy with or without aspiration is usually included in the staging workup for patients with non-Hodgkin's lymphoma (NHL). According to the National Comprehensive Cancer Network guidelines, BM biopsy is mandatory for lymphoma, but aspiration is optional. Moreover, the role of BM aspiration is controversial. Other studies have shown that BM aspiration morphologically or flow cytometry is often inconsistent with biopsy and is less likely to detect lymphoma than biopsy. There are no clear guidelines regarding results that are positive in BM aspiration and negative in biopsy.
Aims: The aim of this study was to establish guidelines through a comparison of the overall survival (OS) of patients with NHL using morphological method.
Methods: We performed a retrospective analysis of BM involvement in patients with newly diagnosed NHL in the Korea University Hospital from January 1991 to December 2016. OS was compared according to the BM groups, which were divided into three groups: the group without BM involvement in both BM aspiration and biopsy, the group with atypical lymphocytes only in BM aspiration, and the group with BM involvement in biopsy regardless of BM aspiration results. Atypical lymphocytes were identified as positive in BM aspiration if they displayed cleaved nuclei, vacuolation, and granulation including lymphoid aggregates, leukemic presentation of mature B-cell neoplasm, and lymphoma associated hemophagocytic lymphohistiocytosis. Reactive changes, or relative lymphocytosis were excluded. OS was assessed using the Kaplan-Meier method, and the log-rank test was used for comparison between the groups. Multivariate analysis were performed using a Cox proportional hazards model.
Results: In total, the data of 1,773 patients, of which 391 patients had indolent NHL and 1,382 patients had aggressive NHL, were reviewed. Of the 1,773 patients, 1,148 (64.7%) yielded negative results on both BM aspiration and biopsy, 30 (1.7%) yielded positive results with atypical lymphocytes only in BM aspiration, and 190 (10.7%) yielded positive results on biopsy. Remaining 405 patients were excluded owing to inadequate results in BM aspiration and/or biopsy. Median follow-up duration was 37.62 months (range, 0-288).
At the time of Kaplan-Meier survival analysis, OS was significantly worse for patients with BM involvement in biopsy compared with those with no BM involvement in both BM aspiration and biopsy (2-year OS, 39.0% v 60.6%; log-rank P<0.001). However, there was no significant difference in OS between patients with atypical lymphocytes only in BM aspiration and those with no BM involvement in both BM aspiration and biopsy (2-year OS, 42.8% *vs* 60.6%; log-rank P=0.184). Patients with atypical lymphocytes only in BM aspiration also had no significant difference compared with those with BM involvement in biopsy (log-rank P=0.291; Figure 1).
Multivariate analysis was performed by adjusting survival related variables such as sex, age, lactate dehydrogenase, Ann Arbor stage, Eastern Cooperative Oncology Group performance status, number of extranodal sites, lymphoma characteristics (indolent *vs* aggressive), and transplantations. The classification according to BM involvement remained a significant prognostic factor for OS (P<0.001). However, in the subgroup analysis, the group with atypical lymphocytes only in BM aspiration showed no significant difference compared to the group without the BM involvement in both BM aspiration and biopsy (Odds ratio, 1.915; 95% confidence interval, 0.940–3.903; P=0.074). Therefore, the detection of atypical lymphocytes only in BM aspiration had no significant difference in the OS even when the relevant factors were corrected.
Summary/Conclusions: This study suggests that the detection of morphologically atypical lymphocytes only in BM aspiration, but not in biopsy, is not significant in predicting the OS of patients with NHL. Therefore, even if atypical lymphocytes are detected during BM aspiration in patients with NHL, it may not be sufficient to judge the BM involvement and predict the OS of these patients.



Kaplan–Meier curves of overall survival according to the BM groups.

***IN VIVO* IMAGING OF LUMINESCENT DIFFUSE LARGE B-CELL LYMPHOMA XENOGRAFTS COMBINED WITH MASS SPECTROMETRY IMAGING IDENTIFY SPECIFIC MOLECULAR ALTERATION DURING R-CHOP RELAPSE.**

C. Côme[1,*], F. Barré[2], F. Dewez[2], R. Heeren[2], B. Cillero Pastor[2], A. Lund[3], K. Grønbæk[1]
[1]Epigenomlaboratoriet, Rigshospitalet Dept. 3733, Bartholin Instituttet, Copenhagen N, Denmark, [2]Division of imaging mass spectrometry, M4I institute, Maastricht, Netherlands, [3]Lund Group, Biotech Research and Innovation Centre , Copenhagen N, Denmark

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common B-cell non-Hodgkin's lymphoma (NHL) throughout the world, comprising 30–35% of all NHLs, with approximately 71 000 new cases and 19 000 deaths estimated for 2014. Currently, R-CHOP, a combination of immunotherapy (Rituximab, targeting the cell surface protein CD20 expressed by B cell lymphoma) and chemotherapy (Cyclophosphamide, doxorubicin, vincristine and prednisone), remains the most commonly used regimens for newly diagnosed advanced DLBCLs. However, as it is a biologically aggressive disease, up to one-third of patients will ultimately become refractory to initial therapy or relapse after treatment and display poor survival outcome, underlying the urgent need for novel therapeutic approaches based upon selective molecular targets. We are combining *in vivo* luminescent/fluorescent DLBCL xenograft models with mass spectrometry imaging (MSI) analysis to study the tumors characteristics during R-CHOP treatment and relapse. The *in vivo* imaging approach allows us to precisely quantify tumoral development and response to therapy, as well as to differentiate tumoral cells from the tumoral micro-environment. On the other hand, MSI technique provides information regarding analyte composition at an almost cellular level. Therefore, we can identify, localize the molecules, proteins, drugs or metabolites. 2 types of analysis are performed: i) comparison between primary untreated tumors and tumors relapsing from R-CHOP therapy. ii) study of the therapy resistant and sensitive areas of each tumor.
Aims: Our aim is to investigate and analyze the various chemical composition of DLBCL xenografts during tumoral development and R-CHOP treatment relapse, in order to identify yet uncharacterized targets that could become alternative targets for therapy.
Methods: 10 millions cells of a U2932 lymphoma cell line were xenografted into 60 athymic nude immuno-deficient mice . Tumoral growth was repeatedly quantified in a non-invasive manner based on tumors' luminescent signal using the *in vivo* imaging system (IVIS) Lumina II. R-CHOP treatment was applied to mice after primary tumoral growth. 2 types of samples are generated: i) untreated tumors, ii) tumors realpsing from R-CHOP
Mass spectrometry imaging is then used to analyze and compare the chemical and biological profiles of DLBCL xenografts at these stages of tumoral growth.
Results: *In vivo* imaging allows us not only to precisely assess primary tumor

development but more importantly, to monitor accurately response to R-CHOP and relapse from this therapy. The tumors at different stages of response to R-CHOP therapy are being analyzed and compared from lipidomics, metabolomics and proteomics point of view. Primary analysis indicate very distinctive metabolomics and lipidomic profiles between relapsed and non treated tumors.
Summary/Conclusions: Combining IVIS and MSI allow us for a better understanding of the disease and the treatment effects and the possible mechanisms allowing tumor cells to escape therapy. We are currently investigating in more details these different lipidomics, metabolomics or proteomics signatures between the different stages of DLBCL response to R-CHOP treatment in order to identify new candidates for alternative therapies.

PB2069

THE PROGNOSTIC ROLE OF INDOLEAMINE 2,3-DIOXYGENASE EXPRESSION IN HODGKIN'S LYMPHOMA.

T. Skrypets[1,*], O. Novosad[1], N. Svergun[2], O. Skachkova[2], O. Gorbach[2], V. Sokolov[3], N. Khranovska[2], I. Kryachok[1]
[1]Oncohematology, [2]Experimental Oncology, National Cancer Institute, [3]Thoracic surgery, Clinical Hospital №18, Kiev, Ukraine

Background: Indoleamine 2,3-dioxygenase (IDO) is an inducible enzyme that catalyzes the initial and rate-limiting step in tryptophan along the kynurenine pathway. IDO is a key factor maintaining immune tolerance and expression and it correlates with poor clinical outcome in different types of cancer and hematological malignancies. It also plays a role in a lot of pathophysiological processes, such as antitumor and antimicrobial defense. IDO causes immunosuppression in the tumor microenvironment by tryptophan breakdown. Although, only several reviews have been made to evaluate IDO prognostic value and its expression value in hematological malignancies.
Aims: The aim of the study was to assess the impact of the IDO expression on clinical outcome in patients with Hodgkin's lymphoma (HL).
Methods: A total number of 35 patients with HL were included in the group (10 males and 25 females; median age: 17-60 years, range: 38.5 years). Early stages (I-II) and advanced stages (III-IV) were diagnosed in 48.5% (17/35) and 51.4% (18/35) of patients, respectively. B-symptoms had 37.1% (13/35) of patients at the time of diagnosis. Patients were treated with ABVD or BEACOPP (14/esc) and radiation therapy. The mRNA expression level of IDO was measured in pre-treatment tumor tissue specimens from HL patients using real-time qPCR analysis.
Results: For 35 patients with HL, the overall response rate after the first-line therapy was 88.6% (31/35). Progression of the disease during the therapy was observed in 11,4% of patients (4/35). Among the patients, who achieved a remission, 9 had relapses. In our study, only 20% (7/35) of HL patients were IDO-positive (IDO^+), while the majority of cases in the group (80%, 28/35) were IDO-negative (IDO^-). There were no significant differences in IDO expression between histological subtypes of HL. We also did not find any association between stage of disease and IDO expression in our study. Patients with the absence of IDO expression tended to have a better response to the 1st line chemotherapy comparing to patients with positive IDO expression. The overall response rate was achieved in 71.4% (5/7) of IDO+ cases and in 92.9% (26/28) of IDO- cases. The relapsed/refractory disease was more frequently found in HL cases with IDO^+compared IDO^-expression (28.5% (2/7) *versus* 7.1% (2/28), respectively, $p<0.05$). We did not register any death of patients in IDO- group, while one patient in IDO+ group died during the follow-up period (median duration – 37 months; range 10–65 months). ROC analysis revealed that the expression of IDO in the tumor is an important marker which is associated with clinical outcome of HL patients (Se=46.2%; Sp=95%; AUC=0.71, p=0.004).). The presence of IDO expression in pre-treated HL biopsies was associated with the reduced event-free survival (EFS) in HL patients. A 4-year EFS rate for IDO^+ HL patients was 50% compared with 73% for IDO-negative HL patients (p=0.002). The prognostic significance of IDO^+ expression in clinical outcome of HL (EFS) was also confirmed by multivariate analysis (HR=2.9; 95%CI 0.8-10.1, p=0.006).
Summary/Conclusions: On the base of the study, our findings suggest that IDO might be a promising marker for HL prognosis as well as represents an attractive target for HL immunotherapy in patients with poor outcome.

PB2070

SECONDARY CHROMOSOMAL ABNORMALITIES AND THEIR IMPACT ON TREATMENT OUTCOME IN PEDIATRIC BURKITT LEUKEMIA.

S.I. Salem[1,*], H. Abdelrahman[2], M. Tantawy[3], S. Talaat[2], R. Hamdy[4]
[1]Clinical Pathology, [2]Pediatric Oncology, NCI, Cairo University and Children Cancer Hospital Egypt-CCHE, [3]Clinical Pathology, [4]Research Department, Children Cancer Hospital Egypt, 57357, Cairo, Egypt

Background: Burkitt leukemia (BL) constitutes around 13.5% of pediatric mature B-cell non Hodgkin's lymphoma. It is characterized by translocation involving the *MYC* gene to one of the immunoglobulin genes. The clinical significance of secondary chromosomal abnormalities associated with this characteristic translocation remains unknown.
Aims: We aim to analyze the impact of secondary chromosomal abnormalities on treatment outcome in pediatric Burkitt leukemia.
Methods: Patients with BL presenting to Children Cancer Hospital in Egypt-57357 (CCHE) from July 2007 till end of December 2015, were reviewed for karyotyping, *cMYC* status by FISH using break apart probes, and secondary chromosomal abnormalities. These results were correlated with survival analysis.
Results: Eighty-seven BL patients were diagnosed and treated during the study period according to the FAB/LMB 96 protocol. Majority were males (77.3%) and above 10 years of age at presentation (42%). Associated central nervous system involvement was diagnosed in 32.9% of the patients. LDH more than 2 times the upper limit was seen in 79.5%, and 52.3% of the patients suffered from tumor lysis syndrome at presentation. Informative karyotype for 66 patients demonstrated translocation of the *MYC* and *IGH* genes in 54 patients (86%) while translocation of the *IGK* and *IGL* were found in 2 (3%) and 7 (11%), respectively. Secondary chromosomal abnormalities were detected in 40 (60%) patients, with 5 or more abnormalities in 4 patients, 3 chromosomal abnormalities in 12 patients, and 2 chromosomal abnormalities in 20 patients. The most common secondary chromosomal abnormality was duplication of chromosome 1q which was found in 16 patients. Other secondary chromosomal abnormalities included structural abnormality of chromosome 14q other than MYC translocation (6 patients), chromosome 6q deletion (4 patients), chromosome 13q deletion (3 patients), marker chromosome (3 patients), loss of chromosome 17p(2 patients), isochromosome 9q (2 patients), translocation of chromosome 13, trisomy 13 and trisomy 9 in one patients each. Relapse or tumor progression on chemotherapy was seen in 16% of the whole group of patients. The 5 year OS was 57.7%, while 5 year EFS was 51.6%. When comparing incidence of relapse in relation to complex karyotype, we found that nine out of 16 (56.2%) patients having complex karyotype experienced relapse whereas relapse occurred in only 6 (12.5%) patients having non-complex karyotype (p-value= 0.005)
Summary/Conclusions: The frequency of secondary chromosomal abnormalities in our series is in concordance with other publications with duplication 1q being the most common. followed by deletion 6q, 13q, and 17p. Complex karyotype was significantly associated with higher incidence of relapse and poor outcome.

PB2071

IGVH SOMATIC MUTATION PROFILE AS PATHOGENETIC SIGNATURE IN SPLENIC MARGINAL ZONE LYMPHOMA AND SPLENIC DIFFUSE RED PULP LYMPHOMA

H.L. Julhakyan[1,*], B. Biderman[1], L. Al-Radi[1], I. Yakutik[1], S. Korzhova[1], A. Kovrigina[1], A. Sudarikov[1], V. Savchenko[1]
[1]National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow , Russian Federation

Background:
Splenic lymphomas (SLs) are rare chronic lymphoproliferative neoplasms with a very indolent clinical course and a non-characteristic phenotype and karyotype. Splenic marginal zone lymphoma (SMZL), a specific type of small B-cell lymphoma and characterized by a peculiar morphology with micronodular pattern of infiltration, biphasic cytology, and the almost constant presence of marginal zone differentiation. Splenic diffuse red pulp lymphoma been introduced as a provisional entity but differential diagnosis with other SLs is needed to be clarified since the therapeutic approaches are distrinct.
Aims: The aim of our study to determine the immunoglobulin variable heavy chain (IgVH) gene usage and somatic mutation patterns in a series of SMZL and SDRP patients.
Methods: We studied 24 patients with SMZL, 40 patients with HCL and 10 patients with SDRPL. Diagnosis was based on standard WHO criteria. In all patients, the diagnosis was based on peripheral blood and BM findings. The baseline clinical and laboratory features as well as follow-up and outcome were recorded for every patient. Rearranged IgVH genes were amplified essentially in reactions that contained only one of the 5' leader region primers for the indicated 6 VH families and a 3'J primer. All PCR reactions were performed using appropriate positive and negative controls. The rearranged VH genes identified for each case seemed to represent functional rearrangements because no stop codons or crippling mutations were identified.
Results: A comparison of the VH genes to reported germline sequences in SMZL revealed that 6 cases used the VH3 family VH gene segments, 2 the VH4 family, 16 the VH1 family segments. The VH1 family genes V1-2 were used in 16 cases. In 4 out of 24 cases (16.67%), IgVH genes were in germline or near germline configuration, whereas in 20 cases (83.33%), IgVH genes were somatically mutated. We have shown no differences in clinical and laboratory characteristics, immunophenotype, outcome or overall survival were found between the mutated and unmutated cases of SMZL. A comparison of the VH genes to reported germline sequences in SDRPL revealed that five cases used the VH3 family VH gene segments and five the VH4 family, one of case with unmutaited IgVH genes.
Summary/Conclusions: Our analysis also showed the selective use of VH1 family genes in a high proportion of SMZL cases (66.67%), while VH4 and VH3 family genes were represented at a lower frequency (8.33% and 25%, respectively). The present study may revealed that SMZL and SDRPL derive from different cellular origin and may use in differential diagnosis.

PB2072

CELL OF ORIGIN ASSIGNMENT USING IMMUNOHISTOCHEMISTRY IS INFLUENCED BY BCL-2 EXPRESSION IN DLBCL PATIENTS TREATED WITH CHEMO-IMMUNOTHERAPY

R. Yassin[1], S. Shieban[2], T. Pasha[1], G. Gmati[1], H. Salama[3], K. Abuelgasim[3], M. Al-Zahrani[1], A. Hejazi[3], A. Ahmed[3,4], M. Damlaj[1,4,*]
[1]Oncology, [2]Pathology & Laboratory Medicine, [3]King Abdulaziz Medical City, [4]King Abdullah International Medical Research Center (KAIMRC), Riyadh, Saudi Arabia

Background: Diffuse Large B-cell Lymphoma (DLBCL) is a heterogenous disease with variable clinical and pathologic presentations. Using gene expression profiling or Lymph2Cx assay, DLBCL can be assigned as germinal center (GCB) or non-germinal center (Non-GCB) subtype. However such assays remain cumbersome or unavailable for routine clinical care. Immunohistochemical (IHC) algorithms, such as the one proposed by Hans *et al.*, are easy to use tools but demonstrated variable concordance to gene expression profiling. Importantly, cell of origin (COO) assignment appears to influence overall survival (OS) but not progression free survival (PFS). Furthermore, antiapoptotic BCL-2 oncogene expression confers prognostic significance in GCB DLBCL but its significance in Non-GCB is unknown.
Aims: To examine the prognostic impact of cell of origin (COO) assignment in conjunction with BCL-2 expression in a cohort of DLBCL patients.
Methods: After due IRB approval, adult patients diagnosed with DLBCL and treated at our institution between 2010 – 2015 were identified. Clinical and pathologic variables were retrospectively abstracted. IHC expression was deemed positive if >30% of staining was observed. Cell of origin analysis was determined by the Hans criteria. All patients were treated with combinational chemotherapy containing rituximb. Patients who died prior to receiving therapy were excluded. Categorical and continuous variables were compared using Chi-squared and Wilcoxon tests, respectively. Time to end point analysis was computed using the method of Kaplan and Meier with log ranks. Relapse, progression or death was considered an event for PFS estimation. Analysis was computed using JMP software, version 11.
Results: A total of 122 patients were identified and analyzed. Median follow up of the cohort was 21.8 (1.47 – 107) months, during which OS was 73.5% and PFS was 59.9%. Stratified by IPI, 2-year OS was 85%, 76.3%, 72% and 49.5% for low, low-intermediate, high-intermediate and high risk patients, respectively (p=0.006). After stratifying patients to GCB and Non-GCB, baseline characteristics between the strata with regards to gender, age, stage, extranodal disease, lactate dehydrogenase (LDH), International Prognostic Index (IPI) and BCL-2 expression were not significantly different.
At 2-years, PFS was significantly higher for GCB *vs* Non-GCB at 72.5% *vs* 48.6%, respectively (p=0.008) but OS was similar at 77.6% *vs* 69.9% (p=0.2) (Figure 1). Interestingly, BCL-2 expression predicted OS irrespective of COO assignment. Patients with BCL-2 expression had a 2-year OS of 55.6% *vs* 56.2% for GCB and non-GCB, respectively. Whereas, patients without BCL-2 expression has a superior 2-year OS at 79.9% *vs* 78.3% for GCB and non-GCB, respectively (p=0.02).

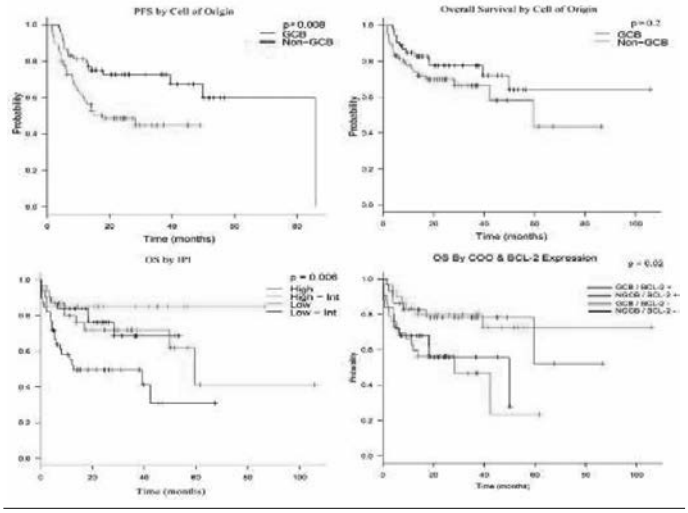

Figure 1.

Summary/Conclusions: COO assignment using IHC demonstrated superior PFS for GCB over non-GCB however this was mitigated by BCL-2 expression. This raises questions regarding the currently presumed pathogenesis of the different subtypes and how to utilize the currently available targeted therapies including BCL-2 inhibitors. These observations warrant further study.

PB2073

ARE DIFFERENCES BETWEEN PEDIATRIC EBV-ASSOCIATED LYMPHOMAS AND CARRIERS REGARDING LATENCY PROFILE AND MICROENVIRONMENT COMPOSITION INVOLVED IN LYMPHOMAGENESIS?

A. Vistarop[1], M. Cohen[1], O. Jimenez[1], F. Huaman [2], E. De Matteo[3], M.V. Preciado[1], P. Chabay[1,*]
[1]Molecular Biology Laboratory, Pathology Division, Ricardo Gutierrez Children Hospital, [2]Histopathological Laboratory, National Academy of Sciences, [3]Pathology Division , Ricardo Gutierrez Children Hospital, Buenos Aires, Argentina

Background: Epstein–Barr virus (EBV) infects more than 90% of the population worldwide. The virus has evolved to persist life-long in B-lymphocytes of infected individuals, but disruption of this tightly regulated B-cell infection could result in EBV-associated B cell lymphomas. In Argentina, primary infection is mostly subclinical and 90% of patients are seropositive by 3 years old. However, EBV presence is statistically associated with Hodgkin lymphoma (HL) and Diffuse Large B cell lymphoma (DLBCL) in patients younger than 10 years, suggesting a relationship between low age of EBV infection and B-cell lymphoma development in children from Argentina.
Aims: Given that viral latent proteins and microenvironment composition play a key role in tumor pathogenesis or control of viral infection, our aim was to compare this scenario in pediatric EBV-associated lymphomas derived from the germinal center (GC) and post-GC with the same areas in tonsils from pediatric EBV carriers, to investigate whether an alteration of microenvironment could be related to lymphomagenesis
Methods: Formalin fixed paraffin embedded (FFPE) pediatric biopsy samples from 26 DLBCL, 55 HL and 41 tonsils from EBV carriers were analyzed. Immunohistochemistry for LMP1, EBNA2, CD4, CD8, Foxp3 and GrB was performed, together with EBERs *in situ* hybridization, and positive cells were counted in the EBV+ milieu.
Results: Latency II pattern (LMP1+ EBNA2-) was predominant in HL (100%), DLBCL (55%), as well as in EBV+ CG in pediatric carriers (90%). CD4+ cell count displayed no differences between EBV+ and EBV- HL or DLBCL (p>0.05, Mann Whitney test), whereas statistically higher CD4+ cells were counted at the EBV+ GC in pediatric carriers (p=0.014, Mann Whitney test). On the other hand, CD8+ cells did not exhibit statistical differences neither in EBV-associated lymphomas nor in benign conditions at the CG, and the same was observed for Foxp3 regulatory cells (p>0.05, Mann Whitney test). In contrast, CD8+ cell count were statistically higher exclusively at EBV+ subepithelial region in tonsils, compared to EBV- counterpart (p=0.0039, Mann Whitney test). Finally, cytotoxic activity evaluated by GrB expression displayed a trend to higher mean in EBV+ DLBCL (p=0.057, Mann Whitney test) but no in HL. Concerning EBV, pediatric carriers did not shown differences in cytotoxic activity according to EBV presence at the CG (p>0.05, Mann Whitney test). In fact, GrB cytotoxic activity was prevalent only at the EBV+ subepithelial region (p= 0.0420, Mann Whitney test).
Summary/Conclusions: Latency II pattern prevails in both pediatric EBV-associated lymphomas and in EBV+ GC from carriers, indicating that LMP1expression may collaborate in the lymphomagenesis process at the GC in pediatric patients from our country. Cytotoxic activity against EBV infection may be only relevant in pediatric DLBCL, and in EBV+ subepithelial regions in pediatric carriers, whereas in EBV+ HL is not increased, in contrast to previously described. CD4+T helper cell response plays a key role at the GC region in EBV carriers, by participating directly as effectors cells, by helping to the overall immune response in the control of viral infection and restrict latency expression to type II pattern, and, ultimately, by limiting the cell outgrowth. Failure in this process may trigger malignant transformation in EBV-associated lymphomas.

PB2074

MICROARRAY EXPRESSION PROFILE OF LONG NONCODING RNAS IN GERMINAL CENTER-LIKE DIFFUSE LARGE B-CELL LYMPHOMA

H. Gao[1,*], Z. Gong[1,2], W. Yang[1]
[1]Hematology, Shengjing hospital of China Medical University, Shenyang, China, [2]Hematopathology, The University of Texas, MD Anderson Cancer Center, Houston, United States

Background: Long noncoding RNAs (lncRNAs) are constantly transcribed and involved in a variety of biological activities. The contributions of lncRNAs to the development of germinal center (GCB)-like diffuse large B-cell lymphoma (DLBCL) remain largely unknown.
Aims: The aim of this study was to investigate the expression profile of lncRNAs in human GCB DLBCL cell lines (OCI-ly1 and OCI-ly19) and normal B lymphocytes by microarray.
Methods: We used Arraystar Human LncRNA Microarray V3.0 for profiling of lncRNAs in our specimens.Sample labeling and array hybridization were performed according to the Agilent One-Color Microarray-Based Gene Expression Analysis protocol (Agilent Technology) with minor modifications. Quantitative

real-time polymerase chain reaction (qRT-PCR) was used to confirm the results of six upregulated and two downregulated lncRNAs. Bioinformatic analysis (gene ontology analysis, pathway analysis and network analysis) was performed to predict the biological functions and potential mechanisms of the differentially expressed lncRNAs in GCB DLBCL.
Results: We demonstrated that 21,539 lncRNAs were expressed in all samples analyzed, of which 1,648 lncRNAs were upregulated and 2,671 lncRNAs were downregulated in GCB DLBCL cell lines (OCI-ly1 and OCI-ly19) (≥2.0-fold, P<0.05). Pathway analysis indicated that 64 pathways corresponded to upregulated transcripts, and 62 pathways corresponded to downregulated transcripts (P<0.05). In addition, a lncRNA-mRNA co-expression network was constructed to identify potential target genes related to the 3 upregulated and 2 downregulated lncRNAs.
Summary/Conclusions: Our data suggested that lncRNAs may play an important role in the pathogenesis of GCB DLBCL, and profile of lncRNAs may be used as a potential biomarker in the diagnosis of DLBCL and predicting its clinical outcome.

PB2075

FLOW CYTOMETRY IN EVALUATION OF EXTRANODAL LYMPHOMA PRESENTING AT UNUSUAL LOCATIONS COMPARED TO NODAL LYMPHOMAS

P. Prakhar[1,*], M. Choudhury[2], S. Sharma[2]
[1]Pathology, Lady Hardinge Medical College, New Delhi, India, [2]Pathology, Lady Hardinge Medical College , New Delhi, India

Background: : Immunophenotyping is a fundamental step in the diagnosis of hematolymphoid neoplasms. Lymphomas arising at extranodal sites can present significant diagnostic challenges due to their morphological diversity. In recent years flow cytometry (FCM) has proven useful in the evaluation of nodal and extranodal lymphoproliferative disorders on samples obtained by surgical specimens or fine needle aspiration cytology (FNAC). For years FNAC has been used for initial evaluation of suspected hematolymphoid neoplasms. Flow cytometry can additionally help in identifying B or T cell nature of neoplastic cells, clonality in case of B-cell neoplasms and any aberrant phenotype. The possibility of detecting CD20 status can help in initiating targeted therapy without undergoing tissue biopsy to do so. FNA cytology with Flow cytometry can serve as a replacement for open biopsy and may help in eliminating the need for more invasive procedures. In this study FCM analysis on cytological specimens, including nodal and extranodal mass from GIT, Thyroid, Kidney, Breast, Tonsil, cerebrospinal fluid and ascitic fluid, was performed.
Aims: The aim of our study was to evaluate the efficacy of flow cytometer for the evaluation of extranodal and nodal lymphomas on 40 patients.
Methods: The currant study was prospectively conducted on 40 patients with a clinical suspicion of hematolymphoid neoplasms. Samples for flowcytometric immunophenotyping (FCI) were obtained by fine needle aspiration (FNA) or by tissue scraping along with samples for cytomorphological, histological and immunohistochemical (IHC) evaluation. Samples collected in Isotone were submitted for FCI on 5-color Beckman Coulter FC-500, using a set of mature and immature antigens markers for lymphoid cells. Results of FCI on cytological specimens along with cytological findings were compared with histological and IHC diagnosis.
Results: Flowcytometric immunophenotyping conducted on extranodal sites included total 10/40 (25%) cases out of which most common site was GIT (4 cases) followed by CNS (3 cases), Kidney (1 case), Thyroid (1 case), Breast (1 case), and Tonsil (1 case). Definite diagnosis using only FCI could be obtained in 25/40 (62.5%) cases in which 6/10 (60%) cases was conducted on exranodal and 19/30 (63%) cases on nodal tissue samples. The remaining 15 cases which could not be categorized by FCI included Hodgkin lymphoma (6 cases), inadequate cellularity (5 cases), Tuberculosis (2 cases), ALCL (1 case), Mantle cell lymphmoma (1 case) and Ewing's/PNET (1 case). Combining FCI with cytological findings definite diagnosis could be found in 33/40 (82%) cases, compared to 38/40 (95%) cases by histological and IHC examination. As per World Health Organization (WHO) classification of tumors of the hematopoietic and lymphoid tissues 2008 most common lymphoma at extranodal site was DLBCL followed by acute lymphoblastic leulemia/lymphoma. Whereas at nodal site most common lymphoma was DLBCL followed by Hodgkin's lymphoma. The estimated diagnostic sensitivity of FCI alone was 60.5% with 50% specificity, similar for both extranodal and nodal tissue samples. Whereas after combing FCI with cytological findings sensitivity and specificity was found to be 78.4% and 100% respectively. Immunophenotyping of lymphoblastic leukemia/lymphoma by FCM on cytological specimens was found to be in 100% concordance with FCI on peripheral blood/bone marrow aspirates.
Summary/Conclusions: Flowcytometric immunophenotyping along with fine needle aspiration cytology offer a rapid, simple and minimally invasive procedure for the detection of hematolymphoid neoplastic cells in solid tissue especially at extranodal sites. Flow cytometry alone may not consistently provides a definite diagnosis of lymphoma subtypes but can be very helpful in diagnosing extranodal lymphoma and nodal lymphoblastic leukemia/lymphoma.
KEYWORDS: Flow cytometry, extranodal lymphoma

POSSIBLE ROLE OF FLOW CYTOMETRY TO CHARACTERIZE INFILTRATING CD4 CELLS IN THE MICRO ENVIRONMENT OF LYMPHOMA TISSUE SAMPLES

R. Di Gaetano[1,*], D. Belvini[1], B. Callegari[1], M.A. De Benedetto[1], E. Pilotto[1], R. Sartori[1], L. Vassallo[2], A. Scapinello[2], T. Giuseppe[1]
[1]Haematology Castelfranco Veneto, [2]Pathology Castelfranco Veneto, Azienda ULSS 2 Marca Trevigiana, Castelfranco Veneto (TV), Italy

Background: In our previous work (Di Gaetano et al, Ann Haematol, 2014) we analyzed by flow cytometry (FC) the rich infiltrated characterizing the microenvironment of Hodgkin lymphoma (HL), mainly comprised of CD4 T lymphocytes . We confirmed that the majority of these CD4 T expressing the activation markers (CD38) but lose the CD26 and we suggested to identify the subset CD4+CD26-CD38+ to identify the non-neoplastic cellular pattern in HL. A subset connectable to regulatory T (Treg) cells, because the low expression of CD26 (DPP4) added to the presence of CD39 (NTPDase) may be responsible for the generation of adenosine, which plays a major role in Treg-mediated immunosuppression
Aims: We wanted to test if this subset may also characterize T infiltrating lymphocytes the lymph nodes of Non-Hodgkin's lymphomas (NHL) and to verify the expressions of the two enzymatic markers (CD26 and CD39) in microenvironments of HL and NHL analyzed by FC
Methods: In 2016 we analyze by FC in lymph nodes of 6 HL and in 32 NHL (12 DLBCL, 10 FL, 5 SLL, 3 MZL, 2 MCL) the CD4 T subset testing the expression of CD26, CD38, CD39.
Results: In CD4 T HL, CD39 is expressed in 44% of the subset and the increased presence (50%) of CD4+CD26-CD38+ cells is confirmed. Compared with HL, the cells of DLBCL are not statistically (t Student test) different: CD38 (64 *vs* 55; p=0,39), CD26-CD38+ (50 *vs* 46; p=0,66), CD39 (44 *vs* 59; p=0,15). While HL and FL cells are significantly different: CD38 (64 *vs* 23; p <0,05), CD26-CD38+ (50 *vs* 18; p <0,05), CD39 (44 *vs* 23; p <0,05). The other three types of NHL, few in number, show a tendency to a significant difference compared with DLBCL.
Summary/Conclusions: The our data show the phenotipic variations in the microenvironements of different types of lymphoma emphasizing of DLBCL the similarity with HL and the difference with FL and other NHL.They also suggest a link between a activated environment (CD38+) and a high CD39, which, in addition to a low CD26, could enhance the generation of adenosine and, therefore, an increased immune suppressive activity. The profile by FC of CD4 T infiltrating can characterize lymphomas in its environment indicating also signals and biological mechanisms representative of possible therapeutic target

PB2077

TREG CD4 PHENOTYPE IN THE PERIPHERAL BLOOD OF LYMPHOMAS

R. Di Gaetano[1,*], D. Belvini[1], E. Pilotto[1], B. Callegari[1], M.A. De Benedetto[1], R. Sartori[1], G. Tagariello[1]
[1]Haematology Castelfranco Veneto, Azienda ULSS 2 Marca Trevigiana, Castelfranco Veneto (TV), Italy

Background: The T regulatory (Treg) cells down-regulate antitumor responses by several distinct mechanisms. One is the adenosinergic pathway which, through ectonucleotidases, sequentially converts ATP to AMP and generates immunosuppressive adenosine. Several studies have demonstrated in humans the overexpression of CD39 (NTPDase) and low adenosine deaminase (ADA) levels, the enzyme responsible for adenosine breakdown, and of CD26, a surface-bound ADA associated glycoprotein. In our previous work (Di Gaetano et al, Ann Haematol, 2014) we analysed by flow cytometry (FC) the T CD4 lymphocytes of solid biopsies, the surrounding neoplastic cells in Hodgkin lymphoma (HL) lymph nodes (LN) and we demonstrated the presence of an activated profile (CD38+) with a reduction of CD26 (CD4+CD26-CD38+). We also confirmed a link of this subset with an overexpression of CD39.
Aims: By using the same FC technique we wanted to explore if, as in the lymph nodes, CD4+CD26-CD38+ subset and high levels of CD39 might characterize the peripheral blood (PB) of HL at diagnosis and possibly to distinguish them from those of B Non-Hodgkin lymphomas (B-NHL).
Methods: We have analysed by FC the PB of 16 healthy controls (HC), 10 HL and 22 NHL testing within T CD4 cells the expression of CD26, CD38 and CD39.
Results: In HC CD26-CD38+ cells were 2.6% of all T CD4 and 5.5% expressed CD39. Compared with HC, the subset CD4+CD26-CD38+ of HL was statistically different (2.6 *vs* 17; p <0.05) as well as in B-NHL (2.6 *vs* 12.9; p <0.05). The expression of CD39 between HC and HL was not different (5 *vs* 9.8; p=0.1), while it was statistically significant between HC and NHL (5 *vs* 19.5; p <0.05).
Summary/Conclusions: Our results may suggest that T CD4 profile in the PB can characterize the patients with HL and B-NHL and this could be probably variable according to the type of neoplasm. The significant presence of CD4+CD26-CD38+ subset in PB of HL and B-NHL would seem to suggest that the low expression/reduction of CD26 of ADA activity may indicate the Treg-mediated immunosuppression. Interesting is the diversity of NHL showing increased CD39 expression on T CD4 lymphocytes probably connected with

the clone of B lymphocytes involved in cancer. This may support that leukemic cells may contribute to create and to characterize an immune-subversive environment and to facilitate immune escape mechanisms. FC analysis of CD26 and CD39, markers likely connected with the adenosinergic pathway, in PB can represent effective parameters to determine and characterize the Treg CD4 in different types of lymphoma and could serve as targets in the follow-up of HL and B-NHL.

PB2078

BCL-2 AND KI-67 AS INDEPENDENT PREDICTORS OF POOR-RISK IPI GROUP OF PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

E. Suljovic Hadzimesic[1,*], S. Radovic[2], A. Sofo-Hafizovic[1], N. Obralic[3], N. Bilalovic[4], A. Kozaric[4], A. Dizdarevic[1], S. Kurtovic[1], V. Bijedic[3], M. Skuric-Tomic[3]
[1]High Dose Therapy Department, Clinical Center University of Sarajevo, Hematology Clinic, [2]Institute of Pathology, Medical Faculty University of Sarajevo, [3]Clinical Center University of Sarajevo, Hematology Clinic, [4]Clinical Center University of Sarajevo, Pathology, Citology and Human Genetics Department, Sarajevo, Bosnia and Herzegovina

Background: Diffuse large B cell lymphoma (DLBCL) is heterogeneous disease ina terms of clinical behaviour, morphology, phenotype and genetics. Gene expression profiling has made a distinction between two entities germinal center B-phenotype (GCB), activated B-center phenotype (ABC). Use of immunohistochemical algorithms for identification of these phenotypes has been translated into clinically feasible approach defining groups as GCB, non-GCB. These algorithms do not provide completely accurate prognostic information so the International Prognostic Index (IPI) which identifies poor- and good-risk patients with diffuse large B cell lymphoma (DLBCL) is still part of all current diagnostic guidelines; however, the majority of patients have an intermediate IPI, with an uncertain prognosis.
Aims: In this study, we investigated the impact of bcl-2, bcl-6, CD10, MUM1 and Ki-67 on IPI as well as impact of GCB and non-GCB subclassification according to Hans and Muris algorithm on IPI risk stratification.
Methods: We have analyzed 50 patients with DLBCL for the expression of bcl-2, bcl-6, CD10, MUM1 and Ki-67 Patients were divided into two groups, the non-GCB, GCB group or favorable group 1 and unfavorable group 2, according to Hans's algorithm and Muris's algorithm. Clinical-pathological, biochemical parameters of disease have been correlated with subgroups of DLBCL and biomarkers individually. The impact of the expression of bcl-2, bcl-6, CD10, MUM1 and Ki67 on IPI-highest score in multiple regression analysis, afterwards in regression equation and variance analyse.
Results: Group with GCB phenotype (defined by expression of bcl-2, bcl-6, CD10 and MUM1) according to Hans's and Muris's algorithm showed positive correlation with good-risk patients identified by IPI. Multiple regressional analysis proved impact of biomarkers on IPI. Following this analysis, bcl2 i Ki67 are independent predictors of poor-risk IPI group of patients, (bcl-2: p 0,0107, Ki67: p 0,0377). The value of F-ratio 2,9845 proves that there is a linear connection between models including all variables bcl-2, bcl-6, CD10,MUM1 and variable depended on the value (IPI)(p 0,0210). The mutual impact of bcl-2, bcl-6, MUM1, Ki67 is significantly related to poor-risk IPI patients.
Summary/Conclusions: Multiple regressional analysis proved impact of biomarkers on IPI. Ki67 and bcl-2 are independent predictors of poor-risk IPI group of patients. Sequential addition of bcl-2 expression, Ki67 and GCB phenotype into the IPI significantly improves risk stratification in DLBCL. These finding can be part of treatment strategies that should be considered in future trials.

PB2079

COMPARATIVE PATHOLOGIC ANALYSIS OF MEDIASTINAL B-CELL LYMPHOMAS: EXPRESSION OF P63 BEST DIFFERENTIATES PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA FROM CLASSICAL HODGKIN LYMPHOMA

H.-J. Kim[1], G. Park[2], S.K. Min[3], H.K. Kim[4], J.H. Han[5], H.J. Cha[6], H. Lee[7], S. J. Choi[8], J.E. Kim[9,*]
[1]Pathology, Sanggye Paik Hospital, Inje University college of medicine, [2]Pathology, Seoul St. Mary's Hospital, The Catholic University, Seoul, [3]Pathology, Hallym University Sacred Heart Hospital, Anyang, [4]Pathology, Soonchunhyang University Hospital, Pucheon, [5]Pathology, Ajou University School of Medicine, Suwon, [6]Pathology, Ulsan University Hospital, Ulsan, [7]Pathology, Eulji University Hospital, Seoul, [8]Pathology, Inha University Hospital, Incheon, [9]pathology, Seoul National University Boramae Hospital, Seoul, Korea, Republic Of

Background: Mature B-cell lymphomas of the mediastinum include primary mediastinal large B-cell Lymphoma (PMLBCL), classic Hodgkin Lymphoma (CHL), B-cell lymphoma unclassifiable, with features intermediate between diffuse large B-cell lymphoma and CHL (gray zone Lymphoma) and others. PMLBCL and mediastinal CHL, mostly nodular sclerosis (NS) share many clinicopathologic characteristics, however, therapeutic options and responses are quite different.
Aims: We aimed to find distinctive histolologic or immunohistochemical findings to better differentiate PMLBCL and CHL of the mediastinum.
Methods: A total of 32 cases of mediastinal B-cell lymphomas consisting of PMLBCL (N=16), CHL (N=13), and gray zone lymphoma (N=3) were collected from 6 university hospitals from Korea. Immunohistochemistry (IHC) for various cell lineage markers and EBV *in situ* hybridization were performed to confirm the diagnosis, and additionally, expression of P63, GATA3 and cyclinE was investigated.
Results: Most clinical features were overlapped between PMLBCL and CHL except more frequent disease progression and mortality in PMLBCL ($p<0.05$). In pathologic review, presence of epithelioid granuloma favored CHL ($p=0.078$), whereas fine reticulated fibrosis was unique for PMLBCL ($p<0.001$). By IHC, P63 was predominantly positive in PMLBCL (15/16) than CHL (2/11) with the highest diagnostic power ($p<0.001$). GATA3 was expressed in the majority of CHL (9/12) compared with PMLBCL (0/16) ($p<0.001$). Expression of cyclinE was rarely found in a minor population of PMLBCL.
Summary/Conclusions: Expression of P63 in the tumor cells, even focal, is the most helpful feature to distinguish PMLBCL from mediastinal CHL. Additional diagnostic markers include GATA3 in CHL and reticular fibrosis in PMLBCL.

PB2080

CASTLEMAN'S DISEASE: HISTOLOGICAL SUBTYPES AND MICROVESSEL DENSITY

A. Mikhailov [1,*], V. Baykov [2], S.S. Bessmeltsev [3], G. Raskin[4], V. Rugal [5], N.Y. Semenova[3]
[1]Department of hospital therapy and cardiology, North-Western state medical university n.a. I.I.Mechnikov, [2]Department of pathology, First St.-Petersburg state medical university n.a. I.P.Pavlov, [3]Russian research institute hematology and transfusiology, [4]Department of pathology, Russian National scientific centre of Radiology and surgical technologies, [5]Department of pathology, Russian research institute hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: Castleman`s disease (CD) is a rare non-clonal lymphoproliferative disorder. Most of the cases are characterized by increased vascularity in the affected tissue. The disease falls into two major histological variants: plasma cell type and hyaline vascular type. However, the correlation between microvessel density and the subtype of the disease has not been established yet.
Aims: To investigate the association between microvessel density and histological type of CD.
Methods: Twenty-eight lymph nodes from patients diagnosed with CD were used for the study. The age of the patients ranged from 24 to 65 years, 14 were male and 14 were female. Three nodes without evidence of metastasis removed for breast cancer were used as controls. The diagnosis of hyaline vascular CD was based on overall preserved immunoarchitecture with typical angio-follicular hyperplasia, circular arrangement of mantle cells around hyalinized germinal centers ("onion skin" pattern). The plasma cell type of CD was confirmed by presence of perifollicular sheets of CD138+ plasma cells. Vessels were labeled with CD34 immunostain. Slides were scanned by the whole slide digital Panoramic scanner. Percentage of blood vessel area (vessel density index) was calculated using Panoramic Viewer software, statistical analysis was conducted with Student's t-test.
Results: The plasma cell variant of CD was diagnosed in 8 patients, the hyaline vascular variant – in 20 patients. In control group vessels occupied 10±1,0% of the area. In patients with plasma cell variant percentage of blood vessel area was increased to 15.1±1.4% ($p<0,05$). Patients with hyaline vascular CD were divided into 2 groups depending on the vessel density index. In 15 patients (75%) percentage of vessel area was 6.8±2.3%, which was somewhat lower than in patients with plasma cell variant (not statistically significant). In 5 patients (25%) with hyaline vascular CD, the percentage of vessel area was higher - 12,3±1,5% ($p<0.05$) and did not differ from levels in patients with plasma cell variant.
Summary/Conclusions: The highest index of vessel density in the lymph nodes with CD was observed in plasma cell variant. In hyaline vascular variant, the index was characterized by significant variability, which could reflect the heterogeneity of this type of the disease. Increased density of blood vessels in the lymphoid tissue may be considered as a possible target for angiogenesis inhibitors, especially in patients with progressive disease.

PB2081

PROGNOSTIC SIGNIFICANCE OF IMMUNOHISTOCHEMICAL MARKERS IN R-CHOP TREATED DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS

A.-M. Picleanu[1,*], S. Patrascu[2], L. Mogoanta[3]
[1]Hematology, Filantropia Hospital Craiova, [2]Surgery, Emergency Hospital Craiova, [3]Histology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background: Despite its clinical, morphological and molecular heterogeneity, diffuse large B-cell lymphoma (DLBCL) is the most frequent lymphoid malig-

nancy in adults. The role of immunophenotype variability for the therapeutic outcome has long been the cornerstone for DLBCL management strategy.
Aims: To evaluate the immunophenotypic characteristics of DLBCL and the prognostic significance of specific biomarkers such as bcl2, bcl6, CD 10 and MUM1, in a population-based cohort of patients treated with R-CHOP.
Methods: We performed a retrospective assessment of all cases of DLBCL diagnosed at our institution between 2005-2013. The immunohistochemical expression patterns of all DLBCL patients were analyzed and correlated with the therapeutic response to R-CHOP regimen.
Results: The study included 101 patients diagnosed with DLBCL, with a median age at diagnosis of 57.1 years (19-90 years) and male/female ratio of 1.3/1. Ninety-one patients were eligible for R-CHOP treatment. The median follow-up was 41 months. Out of the 90 cases analyzed by immunohistochemistry CD 10, BCL2, BCL6 and MUM1 expression was found in 17.6%, 50.5%, 72.7% and 81.8% of cases, respectively. Negative expression for CD10, as well as positive expression of BCL2 were adverse prognostic factors for 3-years overall survival (OS) and disease free survival (DFS) (OS for bcl2: 72.3 *vs* 89.7, p<0.05, OS for CD10: 84.1 *vs* 75.1, p<0.05). BCL6 and MUM1 expressions, however, did influence neither OS nor DFS.
Summary/Conclusions: This study confirms the prognostic value of a multimarker assessment which includes bcl2, bcl6, CD 10 and MUM1 expression for patients R-CHOP therapy.

Other Non-malignant hematopoietic disorders

PB2082

LYMPHOID NEOPLASMS: A REALLY IMPORTANT TRIGGER IN HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

V. Martinez Robles[1,*], S. Calleja[2], B. Ballina[1], S. Cerdá[1], S. Fernández-Ferrero[1], F. Escalante[1], F. Ramos[1], J.A. Rodríguez-García[1]
[1]Hematology and Hemotherapy, [2]Inmmunology, Complejo Asistencial Universitario de Leon (CAULE), Leon, Spain

Background: Triggered by several conditions Hemophagocytic lymphohistiocytosis (HLH) is an unusual, aggressive and life-threatening dysfunction caused by an excessive immune activation. It has become more recognized over the past decade. HLH was first described in 1939 by Scott and Robb-Smith, next case was reported in 1952 by Farquhar and Claireaux describing two infant siblings with progressive and lethal cytopenias, hepatosplenomegaly, and fevers with autopsy showing hemophagocytosis. A lengthy and unstoppable activation of antigen-presenting cells (macrophages, histiocytes) and CD8+ T and NK cells is characteristic. This condition leads to an important hyperinflammatory situation and organ damage including splenomegaly, fever, cytopenia, hypertrigliceridemia and/or coagulapathy. Histiocyte Society (HS) criteria have been applied for diagnosing HLH, however not all of them are usually showed at the presentation. This disease can be described in two different scenarios: primary (usually in children, genetic, and known as familial form) and secondary (acquired). It can be triggered by a large variety of events that disrupt inmune homeostasis. When we talk about triggers, we can divide them in two broad categories, those that cause inmune activation and those that lead to inmune deficiency. Lymphoid neoplasms can be both.
Aims: Due to the lack of publications about HLH secondary to Lymphoid Neoplasms (LN), we would like to analyze the casuistry of our hospital and making a comparison with the current literature.
Methods: We conducted a retrospective analysis through medical files of all patients with suspected diagnosis of HLH between 1994 and 2017 in our in patient ward. Clinical features, age, diagnostic criteria proposed by the HS, etiology, treatment and evolution were analyzed. In our study 18 out of 50 patients met the requested criteria for HLH diagnosis.
Results: We report 10 LN secondary cases (4 males, 6 females). The median age at diagnosis was 60,5 years, ranged between 46 and 80 years. In all of them, but in one, who presented long-term pancytopenia, symptoms were developed very fast. The most frequent causes of consultation were cytopenia and general syndrome. In two of them HLH was diagnosed with LN relapse, in one patient during a transformation from a low-grade B-cell lymphoma to DLBCL (Diffuse large B-cell lymphoma), in 6 of them we diagnosed LN and HLH concomitantly, and in the last one coinciding with a Richter Syndrome. Four of 10 were secondary to T-cell neoplasm. All patients met 5 o more HS diagnostic criteria. In only 3 of them HLH was healed. One patient is still in remission. Nine died, 7 of them due to HLH complications. Treatment was chemotherapy (depending on their LN) in almost all of them. Fluctuations were detected among activity HLH parameters due to LN response. Detailed characteristics of patients are shown in Table 1.

Table 1.

Case	Age (Yrs)	Sex	BCC (PMN/Hb/Plt) (x10e/uL/gr/dL /x10e/uL)	LDH (U/L)	Trg (mg/dL)	Fibri (mg/dL)	Ferritin (ng/dL)	PS	Fever	Adeno-pat	Splenomegaly	Trigger	Treatment	Evolution	Cause of death HLH	Diagnostic Criteria

10	67	F	4,2/8/98	643	251	235	1015	3	Yes	Yes	Yes	Non agressive Lymphoproliferative Sy to DLBCL Transformation	R-CHOP x 3	HLH complete remission, death due to infection after chemo.	No	5

Summary/Conclusions: HLH triggered by LN is diagnosed in older patients than other causes secondary HLH (46-80 *vs* 4-84 y/o in our center), we think this is because in our experience there are not children or Young adult in HLH due to LN group. We would like to highligt that although LN is a very commom HLH trigger there are a few works describing them in the literature, that is why we would like to spread our experience. We would like to emphasize in he importance of an early diagnosis. Despite being a serious disease, it is still underdiagnosed, reaching the diagnosis most of the times after seeing hemophagocytic phenomena in bone marrow biopsy. Agreeing with literature, main consulting reasons are similar to our series. Correlation between neoplastic activity and inmune activation, as well as test and facts which could predice evolution should be more studied. Finally we would like to address the necessity of considering this possibility in the face of a patient with fever which does not respond to antibiotics and has not clarified citopenia, as well as the importance of conducting cheap and very profitable test such as ferritin or tryglycerides level when symptoms or clinical features of lymphoid neoplasm are not concordant with the expected evolution.

Background: Health networks focused on rare diseases were created following a call for proposals from the French Ministry of Health in the summer of 2013. The main objective of these networks is to facilitate and to coordinate the actions being implemented by all actors involved in treating rare diseases. Of the 23 national networks identified in 2014 in France, the network for rare immunohematological rare diseases "MaRIH" brings together national reference centres and recognized centres of expertise as well as patients' associations involved in treating those pathologies, on behalf of scientific medical societies.
Aims: Improving care, communication and training, pushing forward research development and epidemiological surveillance.
Methods: MaRIH brings together people involved in those medical pathologies: 8 national reference centres, 5 centres of expertise, more than 50 diagnosis and/or research laboratories, 9 patients' associations on behalf of 7 scientific societies.
Results: The main missions of this network are to improve the care, the research and to educate professionals, patients as well to disseminate more information to the general public on these rare diseases. *Improving care*: Thanks to its visibility (events, leaflets, website), MaRIH should help primary care doctors to more quickly diagnose and therefore provide faster and appropriate treatment based on best practice recommendations at the national level (PNDS) as well as international guidelines. The network will also be setting up new multidisciplinary meetings for specific immunological and hematological rare disorders through MaRIH centres so physicians in France or in other countries can have easily an expert opinion for their patients. At the same time, improving the child-adult transition was identified by the steering committee as a top priority. *Communication and training*: MaRIH is involved in organizing many multidisciplinary events in France to improve the visibility of the centres and to provide education on these rare diseases. The 1st annual conference of the network took place on June 25th 2015 and the third one is planned on June 1rst 2017 in Paris. Moreover, a patient's day meeting was organised on January 30th 2016 in Paris to inform on the update status of research on their disease as well as to help patients in daily common problems (sport, psychology, transfusion…). *Pushing forward research development and epidemiological surveillance*: the network has appointed a research project manager for its scientific and strategic committee to support, provide stability for and add value to research centre activities. The research project manager watch out for calls for tender, set-up of new registers and continually monitor the regulations for retrospective and prospective studies, both in France and at the international level. Furthermore, MaRIH supported successfully the application of several of its members for European reference networks (Figure 1).

Figure 1.

Summary/Conclusions: The creation of these new networks allows strengthening the links between the various actors involved in the field to improve care and answer transversal questions. In this way, MaRIH pilot concerted actions to all its members around immunohematological rare diseases by: 1- increasing the visibility of the actors on the web or during events. The MaRIH website includes all the informations of the members as well as recommendations and events (www.marih.fr). 2- communication and training. MaRIH organizes two annual events, one for patients and another one for professionals. Moreover, MaRIH sends clinical cases by email to professionals and produce an annual webcast. 3- pushing forward research development and epidemiological surveillance. Thanks to his research project manager, MaRIH facilitates the submission and the set-up of new registries or clinical studies. In the future, MaRIH will continue and futher develop all these actions, in close collaboration with the French Ministry of health.

PB2084

CLINICAL FEATURES AND ETIOLOGY OF PATIENTS WITH THROMBOTIC MICROANGIOPATHIES

Ü. Ergene[1,*], C. Özlü[1]
[1]hematology, saglik bilimleri univercity, izmir, Turkey

Background: Thrombotic microangiopathy (TMA) is a heterogeneous group of disease that has a fatal pattern of endothelial damage. TMA can be found in association with diverse clinical conditions such as carcinoma metastasis, malignant hypertension, infections, and TTP (thrombotic thrombocytopenic purpura). TTP is a rare, life-threatening multisystem disease, characterized by microangiopathic hemolytic anemia, thrombocytopenia, fever, renal dysfunction, and neurological disorders.
Aims: The purpose of this study is to evaluate the etiology associated with TMA.
Methods: All of the six TMA patients who were newly admitted to our clinic in two months period were enrolled in this study. Effectiveness, response, adverse effects and safety of plasmapheresis were evaluated using laboratory and clinical findings. (See Table 1).
Results: First patient presented with cachexia, thrombocytopenia, and TMA. He did not respond to plasmapheresis and corticosteroid treatment. We diagnosed carcinoma metastasis and liver metastasis, respectively, through bone marrow biopsy and PET(positron emission tomography). We thusly ascertained that TMA was due to carcinoma unknown primary. The second patient presented with general neurological findings like Guillain-Barre Syndrome and paraplegia with renal failure, thrombocytopenia, and TMA. After PLEX and corticosteroid treatment, laboratory and neurological clinical recovery were observed after one month. The third patient had chronic obstructive pulmonary disease and pneumonia in anamnesis. who presented with anemia, thrombocytopenia, fever and pneumonia findings. We conducted PLEX therapy. On the 8th day of PLEX, the patient had anaphylaxis, we performed cardio pulmonary resuscitation. The fourth patient

presented with acute renal failure with malign hypertension. We performed hemodialysis together with PLEX treatment. Because his diagnosis was acute renal failure, malign hypertension, and TMA. The fifth patient presented with epistaxis and sepsis. He had chronic TTP diagnosis from two years ago. We diagnosed the patient as relapse TTP. Early treatment against infection and PLEX increased his platelet counts as early as the second day of treatment. The sixth patient presented with a fever that had been going on for five days. We treated the patient with PLEX together with the corticosteroid. Because his ADAMTS13 level was very low and he had 35% schistocytes.

Table 1.

Features and Findings of Patients

Patient number	Etiology	Age	Gender	Hemoglobin (g/dl)	Platelet	LDH (U/L)	Total Bilirubin (mg/dL)	ADAMTS13 Activity	Shigella Toxin&Shiga toxin-producing Escherichia Coli	Schistocyte Count (%)
1(M.Y)	Carcinoma Metastasis	60	Male	5,6	17000	1063	2,65	89,92	-*	5
2(A.Ç.)	Idiopatic	62	Male	7,8	13000	355	1,21	28,35	-*	20
3(M.G.)	Viral Infection	60	Male	7,9	16000	1308	2,66	58,79	-*	10
4(C.B.)	Malign Hypertension	36	Male	7,6	88000	455	0,81	96,26	-*	4
5(A.K.)	Sepsis	56	Male	10,6	67000	282	0,82	0,2	-*	26
6(A.Y.)	Bacterial Infection	52	Male	9,2	30000	755	1,2	0,49	-*	25

*: negative test

Summary/Conclusions: We diagnosed our first patient with carcinoma unknown primary, who did not respond to PLEX and corticosteroid treatment. The results we received for that patient indicate that PLEX with corticosteroid treatment alone, remain ineffective in cancer-related TMA patients. Etiology of our second patients TMA was idiopathic. His clinical and laboratory findings improved rapidly in response to PLEX and pulse corticosteroid treatment. One viral infection induced TMA patient had anaphylactic reaction receiving his 8th PLEX. Allergic reactions should always be kept in mind when administering PLEX. One patient with TMA and malign hypertension-induced renal failure was successfully treated with PLEX, hemodialysis and antihypertensive treatment. We successfully treated our bacterial infection and sepsis-induced TTP patients with PLEX and antibiotic administration. In second TMA patient, we coupled PLEX with high dosage corticosteroid treatment even though he had an infection. For he had high schistocyte count and atypical neurological findings.ADAMTS 13 activity may only be a guide for diagnosis of TTP, but it is unreliable for a definitive one. In conclusion, diagnosis of TTP and other TMAs is difficult. Etiology, clinical features, laboratory findings should all be taken into account when diagnosing TMA. While it is established that ADAM TS13 deficiency is the major cause in acquired TTP, finding the etiology of other TMAs is determinant for a successful treatment of the latter.

PB2085

HAEMOLYSIS AS SCREENING TEST IN LYSOSOMAL STORAGE DISEASES

L. López De Frutos[1,2,*], J.J. Cebolla[1,3,4], P. Irún[1,3], P. Giraldo[1,2,3]
[1]Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Instituto de Investigación Sanitaria Aragón (IIS Aragón), [2]Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Fundación Española para el Estudio y Terapéutica de la Enfermedad de Gaucher y Otras Lisosomales (FEETEG), [3]Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Centro de Investigación Biomédica en Red en Enfermedades Raras (CIBERER), [4]Departamento de Bioquímica, Biología Molecular y Celular, Universidad de Zaragoza, Zaragoza, Spain

Background: Lysosomal storage disorders (LSDs) are a group of rare inherited metabolic diseases, whose clinical hallmark is organomegaly among others, due to progressive accumulation of several non-catalyzed products inside the lysosomes. This storage leads to intracellular oxidative stress status triggering oxidized metabolites production as oxysterols, which are related to apoptosis and cellular eriptosis, as well as haemolysis dysregulation.
Aims: To evaluate the link between LSDs and haemolysis and if it could be used as a screening test in LSDs.
Methods: The osmotic resistance test (ORT) was evaluated in 150 samples including controls, LSDs carriers (LSDs-C) and LSDs patients (LSDs-P). Briefly, the blood was mixed with different concentrations of sodium chloride solution (NaCl) and the haemoglobin released was quantified by spectrophotometry. The raw data was normalized using isotonic solution (0.9% NaCl). The statistical analysis (non-parametric tests and ROC curves), was computed by IBM SPSS statistics v22 software and all statistical tests will be considered and taken as bilateral significance level α=0.05.
Results: The analysis shown that haemolysis at 0.48% of NaCl allow us to sort out controls *vs* LSDs-C/LSDs-P (AUC=0.726) whereas no significant differences were observed between LSDs-C and LSDs-P (p-value>0.05).
Summary/Conclusions: According to our results the ORT test is an useful screening test in LSDs.

PB2086

CLINICAL SIGNIFICANCE OF ELEVATED SERUM COBALAMIN (VITAMIN B12) LEVELS

I. Yaman Bajin[1,*], E. Sabancı[2], S. Akyan[2], S. Aytac[1], M. Çetin[1], F. Gümrük[1]
[1]Pediatric Hematology, [2]Pediatrics, Hacettepe University, Ankara, Turkey

Background: Hypercobalaminemia is a frequent but underestimated abnormality. Elevated serum cobalamin levels may be a sign of a wide range of diseases like solid neoplasms, haematological disorders like myeloproliferative disorders, chronic myelogeneous leukemia, promyelocytic leukemia, polycythemia vera, hypereosinophilic syndrome as well as liver and kidney diseases.
Aims: We aimed to evaluate the underlying disorders of the patients with high cobalamine levels (>1000 pmol/l) between 01.02.2016- 01.02.2017 in Hacettepe University Pediatric Hematology Department.
Methods: We investigated the patient records of the patients examined between 01.02.2016- 01.02.2017 in our department and included the patients with serum cobalamine levels higher than 1000 pmol/l. We excluded the patients who are taking Vitamin B12 supplement.
Results: There were 46 patients with serum cobalamine levels higher than 1000 pmol/l out of 14367 patients seen between 01.02.2016- 01.02.2017 in our department. The reason to check the cobalamin levels were anemia, neutropenia and thrombocytopenia in most of the patients. Only 2 patients were referred to our department because of hypercobalaminemia. The underlying disorders were found to be leukemia in 3 patient (Acute lymphoblastic leukemia (ALL) n:1, acute myeloblastic leukemia (AML) n:1 , large granular lymphocytic leukemia (LGLL) n:1), myelodisplastic syndrome (MDS) in 2 patients, isolated thrombocytopenia in 4 patients, isolated neutropenia in 7 patients, bicytopenia in 4 patients and aplastic anemia in 2 patients, cobalamine metabolism defects in 10 patients, hypereosinophilia in 2 patients, polisitemia in 1 patient, cystic fibrosis in 1 patient, HIV in 1 patient, FMF (familial mediterrenian fever) in 1 patient, chronic kidney failure in 2 patients, sickle cell anemia in 1 patient, factor 7 deficiency in 1 patient, thrombosis in 1 patient and epistaxis in 1 patient.
Summary/Conclusions: An observed elevation of cobalamin merits the a full diagnostic work up to assess the presence of an early diagnostic marker of these diseases. When we look at the patients except hematological neoplasm and cytopenias, most of the underlying reasons is associated with inflamation and infection, cobalamin was found to be elevated as an acute fase reactant. A certain approach is needed whether to determine the potential indications to search for high serum cobalamin levels and to determine the practical clinical strategy when elevated cobalamin levels discovered.

PB2087

THE HEMATOLOGIC FINDINGS OF INHERITED METABOLIC DISEASE; THEY ARE MORE THAN EXPECTED

I. Yenicesu[1,*], A.E. Sal[2], I. Okur[2], Z. Kaya[1], F.S. Ezgu[2], U. Kocak[1], L. Tumer[2]
[1]Pediatric Hematology, [2]Gazi University, Faculty of Medicine, Ankara, Turkey

Background: Inherited metabolic diseases are pathological conditions that generally develop as a result of impairment of the production or breakdown of protein, carbohydrate and fatty acids. Hematological problems are some of the most frequently observed findings of inherited metabolic diseases. These may be seen together with other systemic findings or sometimes as the first and only diagnostic finding of disease. Early determination of hematological findings has a positive effect on the prognosis of metabolic diseases.
Aims: The aim of this study is to evaluate the incidence of hematological findings in inherited metabolic diseases since there are a few studies about the true incidence in literature.
Methods: Three hundred eighteen patients who were being followed-up within the previous 6 months at Gazi University Department of Pediatric Nutrition and Metabolism, Turkey, were included in the study. Patients' hematological findings were taken from Department of Pediatric Nutrition and Metabolism and hospital data-processing records. Since patients were in different age groups, hematological findings were compared with normal values for each patient's age group. The hematological findings were classified under seven main groups; anemia of chronic disease, iron deficiency anemia, vitamin B12 deficiency anemia, hemophagocytosis, leukocytosis and thrombocytosis. Metabolic diseases were classified according to the textbook of Inborn Metabolic Diseases: Diagnosis and Treatment.
Results: Nine hundred twenty-two hematological examinations of the 318 patients were included to the study, and 282 hematological findings were determined, 127 anemia of chronic disease, 80 iron deficiency anemia, 56 cytopenia and four vitamin B12 deficiency anemia. Leukocytosis (n=1), thrombocytosis (n=5) and hemophagocytosis (n=9) were also observed.
Summary/Conclusions: It was determined that although anemia of chronic disease and nutritional anemia are the most common hematological findings, these may be diagnosed late, while neutropenia, thrombocytopenia, pancytopenia and hemostasis disorders may be diagnosed earlier. Metabolic diseases must be considered in the evaluation of cytopenias, particularly in cases with an atypical cause that are resistant to treatment and have additional accompanying findings. Our study is the most comprehensive one in the liter-

ature, and we think it would positively contribute to the monitoring and prognosis of congenital metabolic diseases.

PB2088

HEMATOTOXIC EFFECTS OF GENERIC TRIAZOLE FUNGICIDES TEBUCONAZOLE ON WISTAR HANNOVER RATS

T. Usenko[1,*], V. Shulyak[1], N. Nedopytanska[1], M. Prodanchuk[1]
[1]L.I.Medved's Research Center of Preventive Toxicology, Food and Chemical Safety, Ministry of Health, Kiev, Ukraine

Background: Pesticides are extensively used in agriculture today. Fungicides based on derivatives of triazole are the most widespread all over the world. Tebuconazole (TB) is one of the most frequently used substance of this group. Literature review confirms that triazole fungicides have the ability to cause different hematotoxic effects.
Aims: Since 2007-2016 years we have investigated 10 test-substances of generic tebuconazoles (purity up to 97%) from different manufacturers with purpose to assess their hematotoxic action on males Wistar Han rats peripheral blood in the subchronic 90-days oral toxicity study (according to SOP and OECD 408 reccomendations in compliance with GLP).
Methods: The Wistar Han males were randomly allotted to four groups. The input controls of peripheral blood parameters were conducted after a period of animals acclimatization. The goal was to evaluate the physiological state of the Wistar Han rats and the blood picture before treatment. Doses 0; 10; 50; 200 mg/kg/bw/day were defined and were the same in all studies. Blood samples for hematological measurements were examined at 4, 9, 13 weeks after TB exposure in the same groups of animals throughout the experiment. Hemoglobin (HGB) concentration, hematocrit (HCT), total amount of erytrocytes (RBC), leukocytes (WBC) and platelets (PLT), mean corpuscular hemoglobin (MCH) were evaluated.
Results: As a result, all generic TBs on high toxic doses level (200 mg/kg/bw/day) had shown the tendencies for quantitative hematological changes. TBs mainly provoked the significant decrease of HGB concentration and RBC count on 4th and 9th weeks of exposure. Morphological changes of RBC (anisocytosis) were seen too. It means that generic TBs had anemic effect. In general, changes of hematological parameters were not principally significant and did not differ from control values at 13th weeks of experiments, except two TB's, which had shown significant decrease of HGB. Also some of generic TBs lead to decrease (leukopenia) or increase (leukocytosis) of leukocytes count in peripheral blood. In case of generic pesticides, the presence of impurities can demonstrate various hematotoxic action. Also the adverse effects on peripheral blood of males Wistar Han rats were observed at a dose of 50 mg/kg/bw/day and demonstrated the lesions of red blood. But abovementioned changes were not so clearly expressed. Any adverse hematotoxic effects at 10 mg/kg/bw/day dose were not observed in all studies.
Summary/Conclusions: As a conclusion, due to our results the triazole fungicides generic tebuconazoles have hematotoxic action. They induce anemia in Wistar Han rats and quantitative white blood cells changes. Today it is very important to investigate the hazardous effects of pesticides on the blood system.

PB2089

WHAT WE CAN DO TO MAKE A STANDARDIZATION AND HARMONIZATION OF APTT?

M. Pamukcuoglu[1,*], M. Falay[2], S.M. Urlu[1], M.A. Ucar[1], F. Ceren[1], S. Dagdas[1], G. Özet[1]
[1]Hematology, [2]Biochemistry, Ankara Numune Education an Research Hospital, Ankara, Turkey

Background: Transfusion enhanced many kind of complication in patients therefore peri-operative coagulation monitoring was suggested before the surgical procedure to protect the patients against bleeding. Also there are some diseases which had bleeding events in surgical procedure or spontaneously. We should detect these kind of diseases and we should examine the correct measure of active parsiel thromboplastin time (APTT) before surgical procedure by detecting the mild ormoderate deficiencies of plasma factor levels and by eliminating the lupus antıcougulant from plasma. This was caused to make the importance of APTT reagents.
Aims: We tried to show the importance of APTT reagents and how to reach the correct measure of APTT in this study.
Methods: We are planning to examine 300 patients, 109 of 300 patients were included as yet. Patient's APTT levels were calculated ACL-TOP analyzer by using three different reagents.First reagent was HemosILAPTT-SP which was sensitive against both plasma factors and lupus anticoagulant. It contains mix collodial silica and normal range of APTT- SP was 25.4-36.9 s. Second reagent was HemosIL SynthASil-SS which was sensitive against only plasma factors.It contains silica and normal range of APTT-SS was 25.1-36.5 s. The third reagent was HemosIL SynthA Fox-SF which was sensitive against only lupus anticoagulant. It contains ellagic asid and normal range of APTT-SF was 21.5-30.4 s.
Results: Forthy-five of 109 patients had normal level of APTT by measuring three types of reagents. Seventeen of 109 patients had long level of APTT by measuring three types of reagents. Twenty of 109 patients had long levelof APTT by measuring Hemosil synhAsil-SS reagent and had normal level with Hemosil SynthAFox-SF and Hemosil APTT-SP. Seven of 109 patients had long level of APTT by measuring Hemosil synhAsil- SS reagent and Hemosil APTT-SP reagent and had normal level of APTT with Hemosil SynthAFox-SF. Twenty of 109 patients had long level of APTT by measuring Hemosil synhAsil-SS reagent and Hemosil SynthA Fox-SF reagent and had normal level of APTT with Hemosil APTT-SP.
Summary/Conclusions: Haemostasis is a complex physiological cascade which was began at the endothelium injury. Many kinds of complex prosedures occured after this injury. Beacuse of this complex cascade pathway, bleeding is not occured every kind of APTT level. Bleeding events usually occured at <%30 level of plasma factors but mild or moderate plasma factor levels can caused bleeing. Therefor sensitivite of APTT reagents are very important. Every kind of APTT reagent do not have equal sensitivite against plasma factor levels, phospholipid composition and concentration in thromboplastin reagent. Several studies suggested that range of APTT should be determinate according to the devices and reagents and also several studies comparied APTT reagents which was included silica, ellagic asid and phospholipids by composed of syntethic or animal orginated and several studies determined a target level of APTT for looking at the plasma factors levels. If we want to get a correct result of APTT, ranges of APTT must be determine according to reagents which was used in APTT devices and APTT reagents must be sensitive against borderlines cases who had a mild or moderate low levels of factors and the presence lupus antıcouglant. We need further studies to make a standardization and harmonization of APTT.

PB2090

ACQUIRED PURE RED CELL APLASIA IN AN ADOLESCENT: COULD IT BE ANYTHING ELSE?

S. Yılmaz Bengoa[1,*], Ö. Tüfekçi[1], M. Erdem[1], D. Kızmazoğlu[1], H. Ören[1]
[1]Pediatric Hematology, Dokuz Eylül University, İzmir, Turkey

Background: Pure red cell aplasia (PRCA) is a syndrome characterised by normocytic (sometimes macrocytic), normochromic anemia with severe reticulocytopenia and marked reduction or absence of erythroid precursors from the bone marrow. PRCA may be congenital, in the form of Diamond-Blackfan Anemia, or acquired which is rather rare in childhood. An immune mechanism interrupting erythroid differentiation is responsible in primary autoimmune PRCA, on the other hand secondary acquired PRCA may be associated with autoimmune/collagen vascular disorders, infections, lymphoproliferative disorders, hematological malignancies. solid tumors and drugs.
Aims: Here we report a 16-year-old male with acquired pure red cell aplasia who was treated successfully with steroids and cyclosporine after elimination of the secondary causes.
Methods: Case: An 16-year-old boy presented with a history of pallor and fatigue noticed three months prior to admission. He had been diagnosed with immune thrombocytopenia when he was 5 years old and had been in remission since that time. There was no history of blood transfusion, chronic illness or any other medication. His physical examination revealed pallor and a 2/6 systolic murmur with no other abnormalities. Complete blood count revealed severe macrocytic anemia and reticulocytopenia with hemoglobin:2.2 g/dL, hematocrit: 6.2%, mean corpuscular volume:108.7 fL, red blood cell: $0.57x10^{12}$/L, reticulocyte: 0.2% and mild leukopenia and lymphopenia. Peripheral blood smear showed macrocytic red cells with occasional tear drop cells. Stool for occult blood was negative. The direct and indirect antiglobulin tests were negative Serum bilirubin, LDH, haptoglobulin, liver function tests and renal function tests were in normal limits. Hemoglobin F was 2.9%. Bone marrow aspiration showed red cell hypoplasia, without dysplasia or giant pronormoblasts and normal myeloid and megakaryocytic series. A high resolution computed tomography of chest ruled out thymoma. Serum immunoglobulins revealed low IgA with normal IgG and IgM levels. Anti-nuclear antibody was negative but anti-dsDNA was positive. Parvovirus B19 DNA and other serologic markers including antibodies to HIV and hepatitis A, B and C were all negative. He was transfused with erythrocytes and discharged with a hemoglobin value of 7.2 g/dL. On his follow-up, hemoglobin levels were observed to decrease again. A diagnosis of primary acquired PRCA was considered and prednisone with a dose of 1 mg/kg/day and cyclosporine with a dose of 6 mg/kg/day were started to maintain through levels of 150-250 ng/mL. His hemoglobin level gradually increased and reached to 12 g/dL and leukopenia and reticulocytopenia resolved completely. Prednisone was tapered after 4 weeks and stopped. He is still on cyclosporine treatment and has been transfusion free with stable hemoglobin levels in the second month of his treatment.
Results: Primary acquired PRCA is very rare in childhood, secondary causes must be elliminated for definitive diagnosis. Our patient was found to have lymphopenia, low immunglobulin A level and positive antidsDNA in further investigations, yet these results are not sufficient for a specific diagnosis like common variable immune deficiency or systemic lupus erythematosus. Therefore we considered primary acquired PRCA as the most possible diagnosis and started immunosuppresive therapy; his clinical follow-up will probably give us further details about the underlying disease.

Summary/Conclusions: Immunosupressive therapy including cyclosporine with or without steroid has been reported as the most effective treatment in primary acquired PRCA. Consistently, we had a dramatic response to immunosuppressive therapy in our patient.

APLASTIC ANEMIA IN CHILDHOOD: A TEN YEARS' SINGLE CENTER EXPERIENCE

A. Apsemidou[1,*], T.-S. Tziola[1], A. Tragiannidis[1], E. Chatzipantelis[1], M. Papageorgiou[1], L. Damianidou[1], T. Papageorgiou[1], T. Koletsa[2], A. Giannopoulos[3]
[1]Pediatrics-Pediatric Hematology/Oncology, [2]Pathology, [3]Pediatrics-Pediatric Cardiology, AHEPA University Hospital, Thessaloniki, Greece

Background: Aplastic anemia in childhood is a rare, life-threating disorder, characterized by peripheral blood pancytopenia and a hypocellular bone marrow without signs of dysplasia or fibrosis. Acquired aplastic anemia needs to be distinguished from inherited bone marrow failure syndromes or myelodysplastic syndromes.
Aims: The aim of this study is to assess the clinical and laboratory findings at the time of diagnosis, the treatment approach and the outcome of children with aplastic anemia treated in our department during the past decade.
Methods: This retrospective study evaluated 9 children with aplastic anemia, who were treated and followed up in the Pediatric Department of AHEPA, during the period 2006-2016.
Results: We identified 9 children with aplastic anemia. The patients' population included 6 (66.7%) males and the mean age at admission was 9.7 years. At the time of diagnosis, the average neutrophil count was 750/mm^3, the Hb count was 8.4mg/dl and platelets count was 8770/mm^3. In all of our cases aplastic anemia was acquired, expect one case of Fanconi anemia. Predisposing risk factors (including drugs exposure, viral infections, chemicals) were identified in 4 patients. Among the 9 studied patients, 3 (33.3%) had moderate-non severe, 2 (22.2%) had severe and 4 (44.5%) had very severe aplastic anemia. All of the patients received immunosuppressive therapy (consisting of antithymocyte globulin, cyslosporine A and steroids), 2 remained transfusion independent, 4 underwent bone marrow transplantation- 2 from a matched related donor and 2 from a matched unrelated donor. One patient with refractory disease received, as an alternative first line therapy, eltrombopag. Complete response was achieved in 22.2%, partial response was achieved in 22.2%, relapse occurred in 11.1% and 44.5% of the patients had refractory disease. The overall survival was 77.8%.
Summary/Conclusions: A remarkable progress has been made during the past decades in the understanding of pathogenesis and management of children with aplastic anemia. Bone marrow transplantation from a matched related donor is the recommended first line therapy resulting in an excellent survival rate that exceeds 90%. In the future the development of targeted strategies for patients and the enhancement of supportive care will further improve outcome and diminish the disease's late complications.

PB2092

CAUSES OF IRON DEFICIENCY ANEMIA IN THE HEMATOLOGY CLINIC – SINGLE CENTER EXPERIENCE

M. Ionita[1,*], I. Ionita[1], D. Calamar[1], D. Oros[1], V. Todorescu[1], C. Ionita[1], C. Sorica[1], H. Ionita[1]
[1]Hematology, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania

Background: Iron deficiency anemia (IDA) is the common nutritional deficiency worldwide. The studies concerning various causes of IDA in adult men are rare, although it is assumed that chronic gastrointestinal blood accounts for the majority.
Aims: Of the study is to evaluate retrospectively adult men with IDA that were hospitalized in our Hematology Clinic.
Methods: Two hundred fifteen male with IDA were enlisted at this study from January 2005 to december 2015. Anemia was defined as Hg <13g/dL using the WHO criteria. IDA was considered present if serum ferritin was 15 ng/mL combined with serum iron concentration <30ug/dL with a transferrin saturation of <10%. Complete physical examination, the history of the disease and fecal occult blood test (FOBT) of three spontaneously passed stools was done in all patients. All patients had complete blood count, serum and total iron binding capacity, and a serum ferritin level. Most patients underwent esophagogastroduodenoscopy (EGD). Colonoscopy was performed if lesion that caused IDA was not found, and/or FOBT was positive.The abdominal CT scan were performed according to clinician's recomandation together with other tests related with blood lost.
Results: The median age was 62 (range 32 to 86) years old. 168 of 215 (78.13%) men with IDA had symptoms such as fatigue, dizzines, or digestive complaints. The history of prior gastrectomy, hemorrhoid, that probably had caused IDA were reported in 32 (14,88%), 43 (20.0%), patients, respectively. FOBT was positive in only 65 (30.23%) subjects. 170 (79.06%) patients underwent EGD. The most common findings from EGD were gastritis (48 patients) and peptic ulcer (39 patients). Seventy eight (36.27%) patients were found to have upper gastrointestinal disorders (20 patients with erosive gastritis, 19 gastric ulcer, 16 duodenal ulcer, 23 gastric cancer. Eighty-nine (41.39%) patients underwent colonoscopy. That showed 44 clinically important lesions that probably caused IDA ; colon cancer in 17 (7.90%) patients, colon polyp in 10 (4.65%) patients and hemorrhoid in 17 (7,90%) patients. Concerning malignant lesions which are responsible for IDA, the malignant lesions were found more frequent in patients older than 50 years accounting for 20.45% (27/132 patients) and patients younger than 50 years 17.80% (13/73 patients).
Summary/Conclusions: This study demonstrated that gastrointestinal blood loss is the main cause of IDA in adult men, and that there is a high rate of malignancy in men older than 50 years.

PB2093

IMPACTS OF CLINICAL AND BIOCHEMICAL PARAMETERS ON KEY HEMATOLOGICAL INDICES IN ADULTS: A COHORT STUDY

C.-C. Chen[1,*], M.-H. Lin[2], Y.-H. Yang[3], C.-E. Huang[1], H.-Y. Tsou[1], C.-C. Hsu[1], Y.-Y. Wu[1]
[1]Department of Medicine, [2]Center of Excellence for Chang Gung Research Datalink, [3]Department of Traditional Chinese Medicine, Chang-Gung Memorial Hospital, Chiayi, Chiayi, Taiwan, Republic of China

Background: Studies in Caucasians have shown that values of hematological parameters could be affected by a wide variety of factors, most notably age and gender. However, parallel work in different ethnical populations, especially from Asia-Pacific region, is lacking. Importantly, it remains largely unknown whether some fundamental variables such as nutritional status, lipid profile, and hepatitis infection (either HBV or HCV) also affect the variation of values in hemogram.
Aims: Therefore, we conceptualize this study to explore through several key parameters regarding their potential impacts on the changes of hemogram.
Methods: Adult individuals aged 18 or older from several adjacent villages in Yun-Lin County, located in the central part of western Taiwan, who came to our hospital for annual health exams were screened for the current study. The work, retrospective in nature, was approved by institutional IRB. Information on age, gender, hemogram, levels of total cholesterol (TC), triglyceride (TG), apolipoprotein B (Apo B) as well as albumin, and results of serological testing for hepatitis B and C infection, was obtained from a centralized digital data base. All the clinical data, after given a coding number for each case, were encrypted and provided to the investigators without identifiable personal information. We analyzed the impacts of various parameters on several key hematological indices.
Results: Overall, 26,497 individuals were included in the current analysis after excluding those with hemogram data fell outside of normal range. Carriers of either hepatitis B (HBV) or C (HCV) who had abnormal liver function (defined by elevated levels of aspartate transaminase or alanine transaminase) were excluded as well. Age, gender, and serum levels of TC, Apo B, and albumin all significantly impacted most key hematological profiles. As the levels of TC and Apo B correlated well with each other (correlation coefficient r=0.82211, p <0.0001, Pearson's correlation), we did not incorporate TC in our multi-variate analysis. Several key variables were found to influence some hematological indices in the multi-variable regression model. Increasing age and male gender negatively affected the platelet count, whereas higher Apo B level was associated with elevated platelet count. Surprisingly, hepatitis C carriers with normal hepatic function had slightly higher platelet number than non-HCV carriers. Gender and serum albumin level were the major determinants of variation in hemoglobin level. Total white cell count increased with male gender and elevating Apo B level but was inversely correlated with change in age and serum albumin level (Table 1).

Table 1.

Summary/Conclusions: The hematological indices are influenced by a wide variety of factors, especially age, gender, and serum level of Apo B. As age,

Apo B, white cell count, and platelet count all impose risk of thromboembolism, further work exploring the interactions and impacts of these parameters on the development of cardiovascular diseases should be mandatory.

PB2094

UNUSUAL DISTRIBUTION OF INTERLEUKIN-10 C-592A GENE POLYMORPHISM IN PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA FROM NORTH-WESTERN RUSSIA

S. Kapustin[1,*], I. Zotova[2], S. Gritsaev[2], J. Sidorova[1], I. Pavlova[3], A. Pavlova[3], S. Bessmeltsev[2]
[1]Laboratory of Biochemistry, [2]Russian Research Institute Of Haematology And Transfusiology, Saint-Petersburg, Russian Federation, [3]Laboratory of Immunohematology, Russian Research Institute Of Haematology And Transfusiology, Saint-Petersburg, Russian Federation

Background: Primary immune thrombocytopenia (ITP) is a rare hematological disease with unknown etiology. It is characterized by heterogeneity of the laboratory parameters as well as the features of clinical manifestation. DNA polymorphism of several cytokine genes has been suggested to modulate the risk of ITP development or/and treatment response in distinct population groups. There is no data on the prevalence of cytokine gene polymorphisms in ITP patients from the North-Western region of Russia (NWR).
Aims: To establish the features of genotypes distribution for several cytokine promoter gene polymorphisms in ITP patients from NWR.
Methods: A total of 68 patients (59 women and 9 men) with chronic primary ITP were involved in the study. The median age of the group was 57 years (range: 24-77). The mean duration of ITP was 7 years (2-48). In 19 (32.2%) women, ITP was diagnosed before 30 years old; 26 (38.2%) patients (5 men and 21 women) were diagnosed at age 30-50 years; 23 (33.8%) patients (4 men and 19 women) developed ITP after 50 years old. The control group consisted of 240 healthy persons originated from NWR. Nucleotide variations in the genes coding for interleukin (IL)-1b (-31T/C), IL-6 (-174G/C), IL-10 (-592C/A) and tumor-necrosis factor alpha (TNFA -308 G/A) were discriminated by PCR and subsequent restriction analysis (PCR-RFLP). Intergroup differences in genotype frequencies were assessed by Fisher's exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated by using the GraphPad Prism 5.0 software.
Results: The frequency of the IL-10 -592CC genotype was slightly increased in the ITP group when compared to controls (65.7% *vs* 54.0% respectively; OR=1.6, 95% CI: 0.9-3.1, p=0.15). Interestingly, this variant of the IL-10 gene was more prevalent among women than men with ITP (71.2% *vs* 25.0% respectively; OR=7.4, 95% CI: 1.4-40.5, p=0.016). When compared to controls, the IL-10 -592CC genotype was significantly overrepresented in the group of women with ITP (71.2% *vs* 54.0%; OR=2.1, 95% CI: 1.1-4.2, p=0.044). On the contrary, in the group of affected men we observed the increase of persons who had IL-10 -592A allele (75.0% *vs* 46.0% in control group; OR=3.5, 95% CI: 0.7-18.3, p=0.15). Genotype frequencies for other studied genes were similar between the patients and control group as well as between women and men with ITP. We have also found almost 2-fold increase of the IL-1b -31CC frequency in women diagnosed before 30 years old compared to other patients (15.8% *vs* 8.2% respectively; OR=2.1, 95% CI: 0.4-10.5, p=0.39). The presence of the TNFA -308A allele was more often seen in patients diagnosed before 50 years old (26.7% *vs* 8.7% in other ITP patients; OR=3.8, 95% CI: 0.8-18.8, p=0.12).
Summary/Conclusions: We suggest that the IL-10 -592CC genotype is associated with increased risk of ITP in women from NWR. On the other hand, the IL-10 -592A allele could be involved in pathogenesis of ITP in men. Further studies are needed to clarify the significance of TNFA and IL-1b gene polymorphism in ITP development.

Platelets disorders

PB2095

COMBINED TREATMENT OF AZATHIOPRINE AND ROMIPLOSTIM IN PATIENTS ITP REFRACTORY TO STEROIDS OR THROMBOPOIETIN ANALOGS

M. E. Mingot-Castellano[1,*], I. Sánchez-Bazán[1], J. Díez-Pastor[1]
[1]Hematology, Regional University Hospital of Málaga, Málaga, Spain

Background: More than 70% of patients with Immune Primary Thrombocytopenia (ITP) respond to steroids, but 40 to 70% relapse in the first year follow-up. The use of romiplostim in this group is effective, although 9% failure has been described. In recent literature, there are clinical cases and small series describing the potentiating effect of combined treatment with thrombopoietin analogues and immunosuppresive drugs such as steroids, cyclophosphamide and rituximab. We have not found references to the combined use of azathioprine (AZA) and romiplostim (ROM).
Aims: To describe our experience in the combined use of azathioprine and romiplostim as a rescue treatment in patients with acute or newly diagnosed ITP refractory to corticosteroids or corticosteroid-dependence and refractary to maximal doses of romiplostim monotherapy.
Methods: We analyzed patients with newly diagnosed or persistent ITP, with corticosteroid-dependence or refractory to steroids and refractary to romiplostim, both in monotherapy. We have considered refractoriness to steroids not reaching platelets higher than $30x10^9$/L. Corticosteroid-dependece as the need for ongoing or repeated doses administration of corticosteroids for at least 2 months to maintain a platelet count at or above 30 $X10^9$/L and/or to avoid bleeding. We considered refractoriness to romiplostim not get platelets greater than $30x10^9$/L with 10mcg/kg/week for at least 3 consecutive weeks. All patients have been diagnosed in a single center with the same physician responsible for the treatment and follow-up. The initial doses of AZA was 100mg/days (2mg/kg/day) and ROM 10mcg/kg/week. Patients have been evaluated every week untill platelets were higher than $30x10^9$/L for to consecutive weeks, after this they were reviewed monthly.
Results: We treated 4 patients (75% female) with a median age at diagnosis of ITP of 53 years old (RIQ, 20-61 years). Treatments received prior to the use of the combination of AZA and ROM were polyspecific immunoglobulins (Ig), steroids (dexamethasone, prednisone) and romiplostim. Responses to steroids and romiplostin in monotherapy were: • Median dexamethasone cycles (40mg/days x 4 days) was 2.5 (2-4 cycles, IQR). The initial dose of prednisone was 1-2mg/kg/days with a median treatment day of 31.5 days (28-60 days, IQR). The type of response to steroids was PR with corticode-pendence in one patient, 3 patients NR. • Median time from ITP diagnosis and romiplostim indication was 9.5 weeks (7-48 weeks, IQR). Median platelets count at the start of romiplostim was $6x10^9$/L ($2-13x10^9$/L, IQR). The median platelet count achieved at maximal doses of romiplostim for at least 2 consecutive weeks was $10x10^9$/L ($3-19x10^9$/L, IQR). Once established the refractoriness to romiplostim, we manteined ROM 10mcg/kg/week and AZA was iniciated at 100mg/day. The median time from romiplostim indication to the association with azathioprine was 9.8 weeks (5.5 to 15 weeks, IQR). The median time to response after initiation of combination of AZA and ROM was 21 days (15-35 days, IQR). The types of response were: • One patient did not respond after 60 days of combined treatment. • 1 patient with RC maintains for 7 months in the absence of active treatment. The combined was necesary during 8 months. • 2 CRs still undergoing combined dose reduction (current dose romiplostim 2mcg/kg/week and azathioprine 50mg /d). Median platelets from onset of dose reduction $169x10^9$/L ($128-176x10^9$/L, IQR). Duration of RC, 7 and 14 months. Non adverse events have been described in combination treatment.
Summary/Conclusions: The use of azathioprine and romiplostim in combination could be a safe and effective alternative in subjects refractory to steroids or corticosteroid-dependence and thrombopoietin analogs alone. More studies are needed to clarify the mechanism of complementation between the two drugs.

AGONIST-INDUCED PLATELET REACTIVITY CORRELATES WITH BLEEDING IN HEMATO-ONCOLOGICAL PATIENTS

B. Batman[1,*], E.R. van Bladel[1], M. van Hamersveld[2], P.C. Pasker - de Jong[1], S.J. Korporaal[3], R.T. Urbanus[3], M. Roest[3], L.A. Boven[2], R. Fijnheer[1,3]
[1]Internal Medicine, [2]Department of Clinical Chemistry, Meander Medical Center, Amersfoort, [3]Department of Clinical Chemistry and Hematology, University Medical Center Utrecht, Utrecht, Netherlands

Background: Prophylactic platelet transfusions are administered to prevent bleeding in hemato-oncological patients. However, bleeding still occurs, despite these transfusions. This practice is costly and not without risk. Better predictors of bleeding are needed and flow cytometric evaluation of platelet function might aid the clinician in identifying patients at risk of bleeding. This evaluation can be performed within the hour and is not hampered by low platelet count.

Aims: Our objective was to assess a possible correlation between bleeding and platelet function in thrombocytopenic hemato-oncological patients.
Methods: Inclusion was possible for admitted hemato-oncology patients aged 18 years and above after written informed consent. Furthermore, an expected need for platelet transfusions was necessary. Bleeding was graded according to the WHO bleeding scale. Platelet reactivity to stimulation by either adenosine diphosphate (ADP), crosslinked collagen-related peptide (CRP-xL), PAR1- or PAR4-activating peptide (AP) was measured using flow cytometry.
Results: A total of 114 evaluations were available from 21 consecutive patients. Platelet reactivity in response to stimulation by all four studied agonists was inversely correlated with significant bleeding. Odds Ratio's (OR) for bleeding were 0.28 for every unit increase in median fluorescence intensity (MFI) [95% Confidence interval (CI) 0.11-0.73] for ADP; 0.59 [0.40-0.87] for CRP-xL; 0.59 [0.37-0.94] for PAR1-AP and 0.43 [0.23-0.79] for PAR4-AP. The platelet count was not correlated with bleeding (OR 0.99 [0.96-1.02]).
Summary/Conclusions: Agonist-induced platelet reactivity was significantly correlated to bleeding. Platelet function testing could provide a basis for a personalized transfusion regimen, in which platelet transfusions are limited to those at risk of bleeding.

PB2097

TUMOR NECROSIS FACTOR-A AND TUMOR NECROSIS FACTOR-B SINGLE NUCLEOTIDE POLYMORPHISM AND CHRONICITY IN EGYPTIAN PEDIATRIC PATIENTS WITH IMMUNE THROMBOCYTOPENIA

N. El-Gharbawi[1], G. Shahin[1], A. Eid[1], N. Diaa[1], M. El-Ghamrawy[2,*]
[1]Clinical and Chemical Pathology, [2]Pediatrics, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Although the etiology of immune thrombocytopenic purpura (ITP) remains unclear, both genetic and environmental factors may contribute to the development of disease. Tumor necrosis factor alpha & beta (TNF-α and TNF-β) are important pro-inflammatory cytokines that play a role in regulation of cell differentiation, proliferation and death, as well as in inflammation, innate and adaptive immune responses, and have been implicated in a wide variety of human diseases. We hypothesized that inflammatory cytokine genes polymorphisms (TNF-α and TNF-β) in ITP pediatric patients may play a fundamental role in pathogenesis of the chronic course of the disease and this might be the base for future specific immunomodulatory therapies for chronic ITP (cITP) in children.
Aims: The current case-control study aimed at detecting TNF-α (-308 G/A) and TNF-β (+252 A/G) genes polymorphism in Egyptian children with cITP and studying their possible association with chronic evolution of the disease.
Methods: The current study included 80 Egyptian cITP patients at Pediatric Hematology Unit, Cairo University (mean age 7.08±3.64 years) and 100 matched unrelated healthy controls. Genotyping was performed using polymerase chain reaction restriction fragment length polymorphism technique (PCR-RFLP).
Results: TNF-α genotyping revealed that wild G/G, heterozygous G/A and homozygous A/A genotypes among cITP patients were 81.2%, 15% and 3.8% respectively *versus* 79%, 20% and 1% in control group, while TNF-β wild A/A, heterozygous A/G and homozygous G/G genotypes among cITP patients were 55%, 40% and 5% respectively *versus* 60%, 28% and 12% in control group, with no statistically significant difference between both groups. Patients having homozygous TNF-α genotype showed statistically significant higher mean age, longer disease duration & lower mean platelet count (p=0.005, 0.024 and 0.008 respectively). TNF-α polymorphism was more frequent among unresponsive patients compared to responsive patients with statistically significant difference. Calculated risk estimation revealed that combined genes polymorphism conferred three fold increased risk of development of cITP (OR=3.491, 95% CI: 1.235-9.869, p=0.015).
Summary/Conclusions: We hereby report a strong association between combined polymorphisms of both TNF-α & TNF-β genes and susceptibility to chronicity of ITP in Egyptian children. Further studies for gene polymorphisms which could affect the pathogenesis of ITP and facilitate the development of new therapeutic modalities are recommended.

PB2098

PROGNOSTIC FACTORS IN PRIMARY IMMUNE THROMBOCYTOPENIA OF CHILDHOOD

A. Gkoutsias[1], T. Palianopoulos[1], E. Pappa[2], E. Papapetrou[3], C. Tsaousi[3], N. Chaliasos[1], A. Makis[1,*]
[1]Department of Pediatrics, [2]Department of Internal Medicine, [3]Hematology Laboratory, University Hospital of Ioannina, Greece, Ioannina, Greece

Background: Primary immune thrombocytopenia (ITP) is an immune disorder with varied course. According the duration of the disease, it is distinguished in newly diagnosed (<3 months), persistent (3-12 months) and chronic (>12 months). International studies have highlighted prognostic factors for each form of ITP in children, but similar studies have yet to be been performed in Greece.
Aims: The evaluation of clinical and laboratory parameters and the identification of prognostic markers for the three forms of the disease in children with ITP from an academic reference center in Greece.
Methods: This retrospective study included 57 children with ITP in the past 13 years, aged 1-16 years (median age 5.2). The following data were recorded: age, gender, preceding infection, bleeding type, duration of symptoms and platelet count at the diagnosis, treatment, disease course and immunological markers and comparison was made among the three types of ITP.
Results: 39 children had newly diagnosed, 4 had persistent and 14 had chronic disease. Due to the small number of children with persistent form they were incorporated in the group of children with newly diagnosed ITP. In chronic ITP children are more likely be above 10 years of age (p=0.015)and to have gradual initiation of the disease (p=0.001) compared with newly diagnosed/persistent group (57% *vs* 21% and 79% *vs* 9%, respectively). Recent history of infection was found mainly in newly diagnosed/persistent group (79% *vs* 21%, p=0.013). Platelet count below 10 x 10^9/L at diagnosis was found more frequently in newly diagnosed/persistent group (79% *vs* 36%, p=0.01). Similar, but not statistically significant difference, was found with mucosal bleedings (70% *vs* 50%, p=0.81). Children with newly diagnosed/persistent disease had less frequently impaired immunological markers (12% *vs* 65%, p <0.003) and received more frequent intravenous gamma globulin and/or corticosteroids (p>0.05). None of the children exhibited severe spontaneous bleeding.
Summary/Conclusions: Even though ITP in children is usually a self-limited disease, with rare serious bleeding complications, the newly diagnosed/persistent and the chronic form of the disease are characterized by different predictive parameters that can be used in clinical practice.

PB2099

CANCER-ASSOCIATED IMMUNE THROMBOCYTOPENIA

G. Pinto[1,*], P. Herrera[1]
[1]Hematology, Hospital Ramon y Cajal, Madrid, Spain

Background: Cases of cancer-associated immune thrombocytopenia (IT) have been reported recently, but there are few reports and case series that describe clinical features and response to treatment.
Aims: We report our experience of 10 years at a single hospital in Spain, in patients with IT concurrent with neoplasia.
Methods: We identified the patients by data search of hospital records from 2006 to 2016, with diagnosis of IT with previous diagnosis of cancer, not related with chemotherapy or radiotherapy, not suggestive of bone marrow infiltration, drug-induced, infection of disseminated intravascular coagulation. For the diagnosis, the examination of bone marrow was not mandatory.
Results: The two most common cancers associated with IT were bladder and lung neoplams, but the occurrence of prior cancer (third part of patients) was not uncommon. The IT can appear at any stages of cancer, and it is mainly detected at the first two years after the diagnosis when the patient have been in acceptable antitumoral response. They usually manifest with very low platelet count <20.000, but not always with evident clinical bleeding. The response to therapy was fast and complete with corticoids (usually in the first week) in the majority of patients, but some cases require the combination second line with immunoglobulins or thrombopoietin receptor agonists, and in the follow-up, the response was persistent without recurrence in the first year post-treatment (Table 1).

Table 1.

Patients with immune thrombocytopenia diagnosed concurrently with cancer

PATIENT	GENDER	AGE	TYPE OF CANCER	STAGE	PREVIOUS CANCER	TIME OF STARTING	BLEEDING PHENOTYPE	NADIR PLATELETS /mm3	TREATMENT	OUTCOME OF IT	TIME OF RESPONSE
1	female	47	BREAST	4	no	SECOND YEAR	without bleeding	10.000	CT	CR	2 days
2	male	60	LUNG	4	no	FIRSTYEAR	gastrointestinal	2.200	CT+IVIG	CR	20 days
3	female	52	LUNG	3	breast	FIRSTYEAR	without bleeding	50.000	CT+TRA	CR	20 days
4	male	77	BLADDER	2	no	SECOND YEAR	epistaxis	2.600	CT	CR	5 days
5	male	80	LUNG	3	no	CONCURRENT	gastrointestinal	30.000	CT	CR	4 days
6	male	88	BLADDER	2	prostate	FIRSTYEAR	without bleeding	17.000	CT	CR	20 days
7	male	55	COLON	4	no	SECOND YEAR	gastrointestinal	1.000	CT	CR	2 days
8	female	86	ENDOMETRIU	1	no	FIRSTYEAR	without bleeding	16.000	CT	CR	4 days
9	female	78	BLADDER	1	breast	FIRSTYEAR	gastrointestinal	2.100	CT+TRA	CR	30 days

Abbreviations: PC: previous cancer; CT: corticosteroids; IVIG: intravenous immunoglobulin; TRA: thrombopoietin receptor agonists; IT: immune thrombocytopenia CR: Complete response (continuous platelets count >30,000 by treatment)

Summary/Conclusions: The CAIT is a rare hematological paraneoplastic syndrome that occur in solid tumors, usually associated to low platelet count but without life-threatening bleeding, requiring therapy with corticosteroids as first line, and generally related with a benign clinical course with a rapid and persistent response.

PB2100

THE ROLE OF MEAN PLATELET VOLUME IN NEONATAL SEPSIS: A RETROSPECTIVE CASE CONTROL STUDY IN A LEVEL III NEONATAL INTENSIVE CARE UNIT

A. Srinivasan[1,*], X. Ameer[1], M. Marron-Corwin[1]
[1]Pediatrics, Harlem Hospital Center, New York, United States

Background: Sepsis is a relatively common diagnosis in the neonatal period. Apart from blood cultures which are the gold standard, C-reactive protein (CRP), total white blood cell count (WBC) and the ratio of immature to mature neutrophils (I:T) are considered to be useful markers of sepsis in the neonatal period. There are a few studies that show that mean platelet volume (MPV) is elevated in infectious disease processes.
Aims: The aim of this study was to investigate whether mean platelet volume is increased in neonates with sepsis.
Methods: Only term neonates were included in the study. Exclusion criteria included: (a) Any neonate born with a genetic defect, (b) Any neonate with suspected immunodeficiency, (c) Any neonate requiring surgery in the post-natal period, (d) Neonates admitted to NICU for hyperbilirubinemia, (e) Neonates requiring extensive resuscitation at birth resulting in documented Hypoxic Ischemic Encephalopathy or requiring transfer to a Regional Perinatal Center. Medical records were reviewed from March 2015 to June 2016 and a total of 114 eligible neonates were included in the study and they were divided into 2 groups: 39 neonates with clinical sepsis (as defined by either culture positivity and/or clinical features plus treatment with antibiotics exceeding 48 hours) and 75 healthy controls (as defined by neonates in whom antibiotics were never started or discontinued when cultures were negative for 48 hours and the absence of clinical features of sepsis). Total white blood cell count, C-reactive protein, immature to total neutrophil count and mean platelet volume drawn on two occasions (first within 24 hours and the second between 24 to 48 hours after delivery) were compared between the two groups.
Results: There was no statistically significant difference in the mean platelet volume between the study group and the control group (p value 0.9 in the first 24 hours and p value of 1 in the 24-48 hour sample). There was however, a statistically significant difference between immature to total neutrophil count and C-reactive protein on both samples (p value <0.0001) (Table 1).

Table 1.

Two-sample t-test for characteristics in the two groups

	Mean (se)		
Measurements	Study	Control	p-value
Age	39.2 (0.18)	39.1 (0.13)	0.4065
Weight (gm)	3409.0 (93.36)	3398.4 (529.70)	0.9156

Chi-Square Test for Gender Frequencies in the two groups

	n (%)		
Gender	Study	Control	p-value
female	31 (41.33%)	13 (33.33%)	0.4052
Male	44 (58.67%)	26 (66.67%)	

Comparison of markers between control and study group

WBC1	14.3 (0.89)	14.5 (0.46)	0.2817
WBC2	20.4 (1.27)	17.9 (0.57)	0.1249
IT1	0.2 (0.03)	0.1 (0.01)	<0.0001*
IT2	0.1 (0.02)	0 (0.01)	<0.0001*
MPV1	8.7 (0.16)	8.7 (0.09)	0.9074
MPV2	8.9 (0.14)	8.8 (0.08)	1.0
CRP1	6.6 (1.98)	0.5 (0.21)	<0.0001*
CRP2	26.4 (4.17)	2.6 (0.44)	<0.0001*

*Used a two-sample t-test. The others used a Mann-Whitney t-test.

Summary/Conclusions: In our study there was no statistically significant difference in the mean platelet volume values between neonates with sepsis and healthy controls. C-reactive protein and immature to total neutrophil count continue to be reliable markers of neonatal sepsis.

PB2101

IS PLATELET TRANSFUSION WARRANTED IN PATIENTS WITH ACUTE TTP REQUIRING CENTRAL VENOUS CATHETER INSERTION?
R. Low[1,*], T. Dutt[2]
[1]Postgraduate Department, Central Manchester Foundation Trust, Manchester, [2]The Roald Dahl Haemostasis and Thrombosis Centre, Royal Liverpool University Hospital, Liverpool, United Kingdom

Background: Thrombotic thrombocytopenic purpura (TTP) has a high mortality rate. The cornerstone of management is plasma exchange (PE) which usually requires urgent insertion of a central venous catheter. Patients often have a platelet count of <50x10^9/L at presentation however, National BCSH Guidance advises against platelet transfusion in TTP due to the perceived high aggregability state and reports of associated fatal thrombosis. The risk of thrombocytopaenia related haemorrhage however creates anxiety and dilemma for the team responsible for line insertion and may lead to delays or unnecessary platelet transfusion.
Aims: The aim of the study is determine the average platelet count at time of line insertion and to see if any bleeding complications are observed.
Methods: We retrospectively reviewed all central venous catheter lines inserted in patients presenting to a regional TTP Centre over a 4-year period from 2012-2016.
Results: A total of 48 patients confirmed to have TTP with an ADAMTS13 <5% underwent line insertion: 94 central venous catheter lines were inserted: 40% femoral, 60%–internal jugular vein. The median number of lines inserted per patient episode was 3, with a range of 1-5. Median presenting platelet count for first line insertion was 25x10^9/L (IQR 9-26 x10^9/L). 70% of lines were inserted by critical care and the remaining 30% by interventional radiology. Platelet transfusion was not administered pre line insertion in any case. No significant bleeding complications were documented during or after line insertion. 5 patients had 'excessive oozing at the insertion site' documented, within the first 24 hours of insertion, for which no intervention was required. There were no deaths related to line insertion.
Summary/Conclusions: In conclusion, this study shows no significant bleeding risk associated with central venous catheter insertion in thrombocytopenic patients presenting with TTP. The results support guidance against prophylactic platelet transfusion in this setting and provide reassurance for teams tasked with central line insertion in this critically unwell patient group.

PB2102

LONG-TERM EFFICACY AND SAFETY OF THROMBOPOIETIN AGONISTS IN ADULT REFRACTORY CHRONIC IMMUNE THROMBOCYTOPENIA
M. Kaliou[1], E. Gavriilaki[1,*], G. Papaioannou[1], Z. Bousiou[1], M. Iskas[1], C. Vadikoliou[1], C. Lalayanni[1], A. Athanasiadou[1], R. Saloum[1], A. Anagnostopoulos[1]
[1]Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: Management of chronic immune thrombocytopenia (cITP) aims not only to increase and maintain platelet counts in safe levels, but also to improve quality of life. Thrombopoietin agonists eltrombopag and romiplostim have been approved in refractory ITP. The lack of randomized studies allows only for real-world data comparison on the two agents.
Aims: In the present study we evaluate and compare long-term efficacy and safety of etrombopag and romiplostim in clinical practice and assess the switching feasibility between the two agonists.
Methods: Treatment with thrombopoietin agonists was initiated in 20 adult patients (pts) with refractory cITP between June 2011-2016. Patients resistant or intolerant to the first agonist switched to the second one. Complete response (CR) was defined as a platelet count of ≥100x10^9/L.
Results: Eltrombopag was administered in 15 pts, 6 male:9 female with a median age of 46 years (19-76 yrs) for 13 months (1.4-54 mo). Patients had received a median of 1 previous treatment (range 1-7): corticosteroids (15/15), intravenous immunoglobulin (5/15), rituximab (2/15), vincristine (1/15), cyclosporine (2/15), romiplostim (2/15), danazol (1/15) and splenectomy (1/15). Before eltrombopag treatment, the majority (8/15) showed grade 4 (WHO) thrombocytopenia. Initial dose was 50 mg and increased to 75 mg daily in 3/15 pts and in combination with corticosteroids that were gradually tapered by the 5th week in 12/15. Median platelets value by the 2nd week of administration was 140x10^9/L (5-450 x10^9/L); whereas, by the 4th week increased to 185x10^9/L (16-500x10^9/L). At the end of follow-up, all patients but one achieved CR with median platelets of 145x10^9/L (60-400 x10^9/L). Regarding adverse events, 1/15 pt presented hemolytic anemia, 1/15 pt hepatotoxicity grade 2 with episodes of thrombocytopenia grade 4 and 1/15 pt pulmonary embolism during the second month of treatment. The latter 2 pts switched to romiplostim. Romiplostim was administered in 9 pts, 4 male:5 female aged 44 years (33-63 yrs) for 40.7 months (22.4-60.1). They had received a median of 3 previous treatments (range 1-8): corticosteroids (9/9), intravenous immunoglobulin (6/9), rituximab (6/9), vincristine (2/9), cyclosporine (2/9), eltrombopag (2/9), danazol (1/9) and splenectomy (2/9). The majority (5/9) presented thrombocytopenia grade 4 before romiplostim. Median platelets number by the 2nd week of administration was 50x10^9/L (8-140 x10^9/L); whereas, by the 4th week increased to 115x10^9/L (20-400x10^9/L). At the end of follow-up, 6/9 patients achieved CR with median platelets at 145x10^9/L (110-400x10^9/L). All patients received concomitant steroid treatment that was gradually tapered and stopped in 6/9 pts. 2/9 pts switched to eltrombopag due to thrombocytopenia grade 3 and 1/9 pt to danazol and low-dose steroids achieving CR. No adverse events associated with romiplostim treatment were reported.
No significant differences were found between the 2 treatment groups. All 4 patients that switched to the other agonist achieved CR without adverse events.
Summary/Conclusions: Our real-world data suggest that both eltrombopag and romiplostim are safe, well tolerated and highly effective in refractory cITP and furthermore, switching to another agonist is safe and effective. Future studies will determine predisposing factors for adverse events and more accurate classification of patients that will allow for better treatment guidance.

PB2103

VITAMIN D RECEPTOR GENE POLYMORPHISMS IN ADULT PRIMARY IMMUNE THROMBOCYTOPENIA
M. Sakr[1,*]
[1]internal Medicine- Hematology, Menoufia University, Cairo, Egypt
Background: Recently, several studies have demonstrated the role of vitamin

D receptor (VDR) polymorphisms in the development of autoimmune diseases. Vitamin D affect both innate and adaptive immune responses that have been blamed in immune thrombocytopenia (ITP) pathogenesis.
Aims: The aim of this study is to assess the association of vitamin D receptor gene polymorphism *BsmI* in cases of adult primary immune thrombocytopenia.
Methods: Vitamin D receptor polymorphism *BsmI* (rs1544410) was detected by Polymerase Chain Reaction followed by Restriction Fragment Length Polymorphism (PCR–RFLP). Deoxyribonucleic acid (DNA) samples were extracted from peripheral blood of 40 ITP patients and 60 geographically and ethnically matched healthy controls.
Results: Statistically significant difference was found in the *BsmI* polymorphism between ITP patients and controls ($\chi^2 = 8.77$, P value=0.01). The *BsmI* polymorphism *B* allele was higher in ITP group than that in controls but in statistically insignificant difference ($\chi^2 = 2.125$, P = 0.145). *bb* genotype played a protective role in ITP incidence.
Summary/Conclusions: This is the first published report on VDR gene polymorphisms in adult primary ITP patients. The *BsmI* genotype was associated with increased risk for ITP incidence with no obvious effect on bleeding severity, platelet count nor site of bleeding.

PB2104

A SURVEY OF THE TREATMENT OF THE PREVENTION OF NAIT IN THE UK AND IRELAND

D. O'Keeffe[1], V. Broderick[1,*]
[1]UHL, Dept of haematology, Limerick, Ireland

Background: Neonatal alloimmune thrombocytopenia, (NAIT) is caused by maternal antibodies generated against alloantigens carried on fetal platelets, which cross the placenta and induce destruction of platelets in the fetus. In most cases the maternal immunisation is triggered by exposure to fetal blood at delivery. As a result, the clinical presentation tends to be more severe in subsequent pregnancies. Recent studies and guidelines have suggested that intravenous immunoglobulin (IVIG) with or without steroids can significantly reduce the severity of thrombocytopenia in subsequent pregnancies.
Aims: We set out to establish if there is consistency in the management of the prevention of NAIT across Ireland and the United Kingdom (UK).
Methods: A survey was set up on Survey Monkey and all members of the UK-Ireland Haematology group were contacted by email with a link to the survey in January 2015. In total 90 individual Specialists were contacted across 70 centres.
Results: 30 responses were received to the following questions. Who manages the prevention of NAIT in your centre? 34% of respondents stated that it was managed jointly by haematologist/feto-maternal specialists, with 26% responding it was overseen solely by haematologists and 40% solely by feto-maternal specialists. Secondly what risk stratification each respondent used to decide risk of NAIT in the current pregnancy? 82% stated that they took into account multiple risk factors but 18% stratified risk based only on the outcome of previous pregnancy. Thirdly how many groups do you define after risk stratification? 60% identified 3 strata of risk (standard, high and very high) with 40% classifying two risk groups (standard *versus* high risk). Fourthly respondents outlined their management of a standard risk group defined as confirmed thrombocytopenia with antibody. 43% give IVIG 1g/kg weekly from 20 weeks, 28% give 1g/kg from 20 weeks increasing to 2g/kg at 32 weeks with 6% starting 1g/Kg IVIG from 24 weeks. 23% referred to feto-maternal specialist to decide IVIG . Just 20% give 0.5mg/kg of steroids from 20 or 32 weeks. For high risk pregnancies defined as confirmed antibody positive with previous intracranial haemorrhage (ICH) after 28 weeks: 36% of centres give IVIG 1g/kg from 20 weeks, 36% give 1g/kg from 20 weeks increasing to 2g/kg at 32 weeks with 14% giving 2g/kg from 20 weeks and 14% initiating at 12 weeks. 40% gave 0.5mg/kg of steroids varying from 12-32 weeks starting. 60% of centres use a very high risk protocol (ICH before 28 weeks) with more intensive IVIG starting at 12 or 20 weeks with steroids of variable intensity and duration. Finally respondents were questioned whether there was a planned delivery time and method for the pregnancy? 58% plan a delivery at 38 weeks with no specific delivery mode. 18% plan delivery at 38 weeks by caesarean section, 8% plan a caesarean section but with no set time and 16% have no specific protocol plan for delivery.
Summary/Conclusions: The results of this survey reveal that the optimal medical management for the prevention of NAIT, namely the medication, dosage and schedule vary widely reflecting the lack of good evidence to guide centres in this very challenging area. Based on this survey we plan with our colleagues in UKOS a prospective study of treatment and outcomes.

PB2105

THE EVALUATION OF REACTIVE OXYGEN SPECIES IN CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA AND HELICOBACTER PYLORI INFECTION *VERSUS* CHRONIC ITP WITHOUT HELICOBACTER PYLORI INFECTION

M.-A. Gaman[1,*], A. M. Gaman[2,3]
[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, [2]Hematology, Filantropia City Hospital, [3]Pathophysiology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background: Chronic idiopathic thrombocytopenic purpura (ITP) is an acquired disease characterized by a low platelet count caused by an immunological peripheral platelet destruction or a decreased platelet production. Several studies have shown increased reactive oxygen species (ROS) levels in chronic ITP and also a possible association between Helicobacter pylori (H. pylori) infection and immunological peripheral platelet destruction.
Aims: To evaluate whether patients with chronic ITP and H. pylori infection exhibit higher ROS levels compared to patients with chronic ITP and no H. pylori infection and whether there are statiscally significant differences between the two groups.
Methods: We studied 29 patients with chronic ITP (median age 39 years) hospitalized in the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, between 2014 and 2016 (informed consent obtained). All patients were diagnosed with ITP, other causes of thrombocytopenia having been ruled out by bone marrow aspiration. The patients were divided in two groups: patients with ITP and H. pylori infection (group A) and patients with chronic ITP without H. pylori infection (group B). Serological tests (ELISA) were used to indicate the presence of a H. pylori infection and reactive oxygen species were evaluated by FORT (Free Oxygen Radicals testing) test from a single drop of capillary blood, at the time of diagnosis, before the administration of any drug (the normal value of FORT is considered less than 2.3 mmol/L H_2O_2), using a CR3000 analyzer (Callegari SpA, Parma, Italy). The differences between the two groups were assessed using the Student T-test and a p-value of less than 0.05 was considered statistically significant.
Results: Group A consisted of 11 patients positive for H. pylori, whereas group B included 18 patients with no H. pylori infection. ROS levels, measured by the FORT test, were elevated in both groups (between 2,8 – 3.6 mmol/L H_2O_2). However, statistically significant differences were found in favour of group A, with higher ROS values than group B. The A group also associated lower platelet counts and more patients pertaining to this group relapsed in comparison to group B.
Summary/Conclusions: In chronic ITP, increased levels of ROS are associated with elevated autoantibody production. Autoantibodies are involved in platelet destruction via highly a immunogenic activity. On the other hand, association of H. pylori infection, via chronic inflammation, led to a supplementary increase in ROS levels and increased platelet destruction.

PB2106

IMMUNE THROMBOCYTOPENIA AND PREGNANCY: A SPANISH CASE SERIES OF 270 PREGNANCIES IN PRIMARY ITP.

T.J. González-López[1,*], J. Bastida[2], P. Olivera[3], I. Jarque[4], S. Bernat[5], B. Sánchez-González[6], E. Bolaños[7], G. Pérez-Rus[8], A.R. Huerta[8], V. Martínez-Robles[9], M.P. Background: Effect of pregnancy on the course of primary immune thrombocytopenia (ITP) is not well known. Besides, due to the lack of clinical assays, evidence about outcome predictors of pregnants and neonates born to mothers with ITP is scarce.
Aims: To evaluate management and results of pregnancy and delivery on pregnant ITP women and on their offspring.
Methods: All women diagnosed of primary ITP (according to international consensus criteria) from 2011 to 2016 in 23 Spanish Hematology Departments who had at least one pregnancy after ITP onset were included in this registry.
Results: We included 270 primary ITP pregnancies from 184 women. At pregnancy diagnosis, we observed a majority of chronic ITP cases (71.4%). At ITP diagnosis, median age of our case-series was 23 years (IQR, 19-29) and median platelet count was 18 x 10^9/l (IQR, 6-35). Median time from ITP diagnosis to pregnancy was 167 months (IQR, 0-366). Median number of pregnancies prior to ITP diagnosis were 1 (IQR, 0-2) with 1 pregnancy (IQR, 1-2) after ITP diagnosis as a median.

50.8% of women received corticosteroids, immunoglobulins (IVIG) (16.9%), rituximab (6.8%) and/or splenectomy (8.4%) as ITP treatments between or before new pregnancies. On the other hand, 26.4% of women needed treatment for ITP during pregnancy, mainly steroids (13.5%) and IVIG (10.2%).
The median platelet-count nadir during pregnancy was 74 x 10^9/l (IQR, 36-172). 127 (47%) pregnancies suffered from non-haemostatic platelet levels (less than 50 x 10^9/l) with 73 (27.0%) women who achieved less than 30 x 10^9/l. 56 (20.7%) women exhibited hemorrhagic symptoms, being 30 (11.1%) of them severe bleedings.
Regarding type of delivery, this was vaginal in 63.4% of pregnancies and cesarean sections 30.5%. Median platelet count at delivery was 110 x 10^9/l (IQR, 76-181). 43 patients (23.4%) experienced 57 bleeding episodes.
We only observed 48 cases (20.4%) of neonatal thrombocytopenia among 235 living newborns.
Summary/Conclusions: Our results are comparable to previously reported studies. No severe bleeding complications during pregnancy and/or delivery were observed in our case series. Rate of neonatal thrombocytopenia, and therefore, newborn bleeding is low.

Background: Immune thrombocytopenia (ITP) consists of various acquired disorders caused by autoantibodies against platelets resulting in increased platelet destruction and impaired thrombopoiesis. ITP is characterized as primary when an underling etiology cannot be identified and secondary when a certain etiology exists. Data concerning ITP characteristics at a national level are limited.
Aims: The purpose of the study was to access systematically the demographic, clinical, laboratory and treatment-related data of ITP in Greece based on the national database (ITP registry) operated and supported by the Hellenic Society of Haematology.
Methods: Patient data were collected over 2013-2016. The data source is a unique database initiated and managed by the Haematology Department of the University of Crete (UoC) and supported by the Center of Information and Communications Technologies of the UoC. The registry has been configured for national and regional base usage considering hospitals as the core unit. A certified researcher/administrator has access to a platform where he/she can record and study patients' data. The entire project has been developed using the robust open source tools of operating systems and Relational Data Base Management System (RDBMS) packages.
Results: We analyzed data from 696 adult ITP patients registered from 14 different hospitals from all parts of Greece. The median age at diagnosis was 53 years (range 15-97 years). Two peaks were observed at the age of 19-30 and 71-80 years. There was a female (60.89%) *versus* male (39.1%) predominance with higher frequency of females in younger (19-30 years) and of males in older (71-80 years) ages. Females appeared with more severe thrombocytopenia. The median platelet count at diagnosis was 15x10^3/ml. The majority of patients presented with hemorrhagic symptoms (70.9%). The main manifestations were cutaneous bleeding (64%), oral cavity bleeding (20.9%), epistaxis (8.9%), menorrhagia (7.8%) and gastrointestinal bleeding (5.5%). 430 patients (61.78%) had primary ITP and 266 (38.22%) secondary ITP. Among these secondary ITP cases, 44.22% were related to infectious agents, 25.74% to drugs, 17.17% to collagen vascular diseases and 12.87% to cancer. Patients with positive ANA antibodies with no evidence of any underlying diseases were included in the primary ITP group. The main patient comorbidities were hypertension (22.64%), thyroid disease (12.32%) and cardiovascular disease (10.17%). Treatment was given in 620 patients at diagnosis. Specifically, 577 (93%) patients were treated with cortocosteroids, 322 (51.9%) with intravenous IgG, 265 (42.7%) with both, and 112 (18%) received other treatments including rituximab (4.8%), anti-D immunoglobulin (4%) and thrombopoietin receptor agonists (4%). The majority of the patients (85%) responded to the initial treatment. Follow-up data for more than one year are currently available in 259 patients (133 with persistent ITP and 126 with chronic ITP). Splenectomy has been performed in 59/696 patients (8.47%).
Summary/Conclusions: Primary ITP is more frequent than secondary ITP in Greece, the disease displays two peaks at the ages of 19-30 and 71-80 years, presents a female predominance and high frequency of hemorrhagic symptoms. Treatment is mainly based on corticosteroids and/or intravenous IgG. Registration and follow-up of larger number of patients and evaluation of response to various treatments are anticipated to extend our knowledge on the pathophysiology and natural history of ITP and may also reveal peculiarities at local level.

PB2108

PRESENTING SYMPTOMS AFFECT OUTCOME IN IMMUNE MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA

J. Khwaja[1,*], F. Alwan[1], C. Vendramin[2], K. Langley[2], M. Thomas[1], J.P. Westwood[1], M. Scully[1]
[1]Haematology Department, University College London Hospital, [2]Haemostasis Research Unit, University College London, London, United Kingdom

Background: Whilst immune mediated Thrombotic Thrombocytopenic Purpura (TTP) has classically been suspected by the presence of a pentad of symptoms (microangiopathic haemolytic anaemia, fever, disturbed neurological function, renal failure, thrombocytopenia), the limitations of this have long been recognized and a wide variety of symptoms are seen on initial presentation.
Aims: A retrospective review of the significance of specific symptoms and their duration on mortality.
Methods: A retrospective review of all consecutive admissions to a single tertiary center between 2009 and 2015. Only patients who required plasma exchange were included. Patients' symptoms and their duration were reviewed in addition to presenting anti-ADAMTS13 IgG antibody levels and ADAMTS13 antigen levels, both of which have previously been found to have prognostic significance.
Results: 106 patients (68% female) were included with a median age of 48. 58% were Caucasian and 19.8% Afro-Caribbean. The mortality rate was 7.4% (n=8). 47% of patients had neurological symptoms on presentation, 24% reported a bleeding history and 12% a recent infection. The most common presenting symptoms were headache (27.4%), bleeding (24%) spontaneous bruising/petechial rashes (19.8%), speech disturbances (encompassing expressive/receptive dysphasia, aphasia, dysarthia and slurred speech, 19.8%) and TIA or stroke like symptoms encompassing hemiplegia or facial weakness/droop (16%). The highest rates of mortality were seen in patients who experienced loss of consciousness (mortality 33.3%), abdominal pain (mortality 22.2%) and heavy bleeding (mortality 16.7%). The anti-ADAMTS13 IgG level was not however significantly higher in these symptoms when compared to others (Table 1) suggesting microangiopathic thrombosis location plays an important role in TTP prognosis. The median duration of symptoms prior to presentation was 7 days (range 1-60 days). 8.5% of patients were asymptomatic, all relapsed TTP. Patients in the highest quartile for symptom duration (>10 days) had significantly higher anti-ADAMTS13 IgG antibody level than those in the lowest quartile for symptom duration (<2 days) (65% *vs* 26%, p=0.002) and may have increased mortality (symptoms <2 days mortality 7.4%, symptoms >10 days 14.3%, p=0.19).

Table 1.

Symptom (n)	Mortality	Antibody (NR: <6%)	Antigen (NR: 74-134%)
LOC (6)	33.3%	44%	2.9%
Abdominal pain (9)	22.2%	50%	3.3%
Heavy bleeding (18)	16.7%	28%	2.9%
Headache (29)	3%	44%	4.5%
Speech Disturbance (21)	4.8%	48%	4.2%
Tia/stroke symptoms (17)	5.9%	42%	4.8%
Pyrexia (16)	12.5%	32%	5.7%
Lethargy (15)	13.3%	58%	7%
Spontaneous Bruising (15)	6.7%	56%	6.4%
Confusion (10)	0%	48%	4.2%
SOB (10)	10%	45%	4.1%

Summary/Conclusions: Whilst there is little difference in the anti-ADAMTS13 IgG antibody and ADAMTS13 levels seen with difference symptoms, there is a wide disparity in terms of mortality suggesting the effect of microangiopathic thrombosis differs by location. Abdominal pain, not previously recognized as a significant symptom in TTP, seems to be a poor prognostic indicator although this should be interpreted with caution given the sample size. Anti-ADAMTS13 IgG antibody level increases with symptom duration and this may lead to increased mortality.

PB2109

NOVEL TECHNIQUES FOR MONITORING GALNZMANN THROMBASTENIA PATIENT UNDERGOING SURGICAL INTERVENTIONS

A. Barg[1,2,*], H. Hauschner[1,2], M. Misgav[1,2], E. Avishai[1], N. Rosenberg[1,2], G. Kenet[1,2]
[1]Institute of thrombosis and hemostasis, Sheba medical center, [2]Sackler Faculty of Medicine , Tel Aviv University, Tel Aviv, Israel

Background: Glanzmann thrombasthenia (GT) patients undergoing surgical procedures are often treated by platelet transfusion. However many GT patients who have been previously exposed to platelets may form antibodies either against the missing αIIbβ3 antigen or directed against MHC-class molecules thus hampering the efficacy of care. Due to the rarity of disease there is paucity of data regarding platelet transfusion protocols during the perioperative period. We herein describe our experience with monitoring the proportion of donor platelets following transfusion, and their contribution to whole blood clot formation.
Aims: To describe the use of flow cytometry (FC) analysis in order to detect donor transfused platelets in A GT patient undergoing a minor surgical procedure and to assess the correlation between FC analysis and the results of Rotational thromboelastography(ROTEM).
Methods: A nine year old female patient with GT underwent teeth extraction. The Patient received platelet transfusion around the procedure. Complete blood counts, ROTEM, FC to detect the number of donor platelets and their ADP dependent activation, were sampled and followed till 7 days post teeth extraction.
Results: Prior to teeth extraction upon injection of local anesthetics patient developed a buccal hematoma probably owing to local blood vessel penetration. The patient did not experience any post extraction bleeding. Hematoma was absorbed within several days. Post transfusion platelets FC demonstrated 20.6%% donor platelets equivalent to 55,620 donor platelets. Platelets activation was determined following ADP addition by examination CD62 antigen expression. Seven days post platelet transfusion FC demonstrated 2.6% equivalent to 8,658 donor plantlets. The decline in the number of active platelets was associated with a reduced clot firmness (MCF) and lower α-angle as assessed by ROTEM (Figure 1).

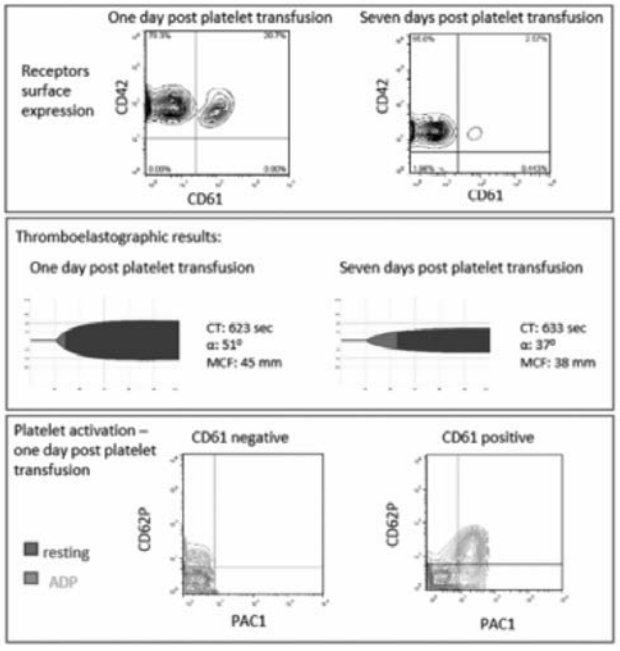

Figure 1.

Summary/Conclusions: Clinical decision making in patients with GT may be aided by application of novel techniques, evaluating the number of active donor platelets and actual clot formation. This data may help making more knowledgeable decisions as for the need for further platelet transfusion or for the need for rFVIIa. Thus leading to improved monitoring and better patients' care.

PB2110

CAN HISTOCHEMICAL C-MPL POSITIVITY IN BONE MARROW BE A PREDICTOR FOR SPLENECTOMY IN IMMUNE THROMBOCYTOPENIA?

I. Yavasoglu[1], N. Gencer[1], F. Cantas[2], F. Doger[3], Z. Bolaman[1,*]
[1]Adult Hematology, [2]Biostatistics, [3]Pathology, Adnan Menderes University Medical Faculty, Aydin, Turkey

Background: Splenectomy is used as the second line therapy in patients with immune thrombocytopenia (ITP). However, there is no parameter predicting splenectomy decision.
Aims: Aim of the present study was to evaluate immune histochemical Cloned Myeloid Leukemia Virus (c-mpl) positivity in bone marrow specimens of ITP patients with or without splenectomy indications.
Methods: Bone marrow specimens were taken from 24 patients who were diagnosed with ITP and who had splenectomy (15 female, 9 male, mean age 50±16) before splenectomy and 30 patients who were diagnosed with ITP but did not have splenectomy (15 female, 15 male, mean age 52±19). c-mpl staining was carried out retrospectively. Immunohistochemical (IHC) staining using Avidin-Biotin complex system (ABC) was conducted. For IHC, dissections prepared from blocks were taken onto poly-L-lysine coated slides (MicroSlides Snowcoat X-tra, Surgipath, Richmond, IL, USA) and kept in an incubator at 37 °C overnight. Dissections were treated with IHC c-mpl (Santa Cruz/sc-13187) stain. Cytoplasmic and nuclear staining was observed in megakaryocytes using IHC c-MPL and vitamin D. Evaluation was made based on the intensity of the staining; *i.e.* negative (0), weak (1+), moderate (2+) and strong (3+) (1). All patients who had splenectomy were in chronic phase of the disease. The present study was supported as a Scientific Research Project by Adnan Menderes University (TPF-15027).
Results: c-mpl positivity was statistically significant in patient group who did not have splenectomy (Table 1). In patient group who had splenectomy, c-mpl was not associated with refractory status.

Table 1. c-mpl positivity in patients group who had and did not have splenectomy.

	with splenectomy(n)	without splenectomy (n)	p value
c-mpl positivity(n)	1	12	‹0.001
c-mpl negativity(n)	23	18	‹0.001
Total (n)	24	30	‹0.001

Summary/Conclusions: Status of c-mpl in ITP is ambiguous. Significant level of positivity in patient group who did not have splenectomy might the useful for splenectomy indication.

PB2111

CLINICAL SIGNIFICANCE OF IMMATURE PLATELET FRACTION MEASUREMENT IN THROMBOCYTOPENIC DISORDERS DURING PREGNANCY

R. Coll[1,*], A. Marull[1], M. Sagüés[1], N. Kelleher[1], O. Jimenez[1], C. Morales-Indiano[1], M. Serrando[1]
[1]Hematology Department, Institut Català de la Salut, Girona, Spain

Background: Thrombocytopenia is the second most common hematologic abnormality during pregnancy and is usually a benign condition. The challenge to the clinician is to weigh the risks of maternal and fetal bleeding complications against the benefits of diagnostic tests and interventions. This condition can also be associated with several diseases, either pregnancy specific or not, such as preeclampsia, HELLP syndrome, or idiopathic thrombocytopenic purpura (ITP). The differential diagnosis between ITP and gestational thrombocytopenia is clinically important with regard to the fetus, due to the risk of neonatal thrombocytopenia. The immature platelet fraction (IPF) is young cells that have recently been released into the circulation, and are considered indicators of bone marrow recovery. They contain a higher concentration of RNA than mature platelets. Measure of immature platelet fraction (IPF) has been suggested as a less invasive and early diagnostic test in the study of thrombocytopenic disorders. Immature platelet fraction can be currently measured by fully automated hematology analyzers providing clinical utility for diagnosing and monitoring thrombocytopenia.
Aims: The aim of this is to know whether IPF can be a useful parameter in pregnant women with thrombocytopenia to predict the potential risk of bleeding.
Methods: Pregnant women with thrombocytopenia were selected (2015-2016); a total of 25 patients (mean age: 33 yrs, range 19-43 yrs) were examined with platelet count <100.000 platelets/μL. Venous whole-blood samples were collected into Vacutainer EDTA-K2E tubes (Becton Dickinson and Company, Plymouth, UK). Complete blood counts and immature platelet fraction (%IPF) were immediately analyzed within 2 h of blood withdrawal by Sysmex XN20 system (Sysmex Corporation, Kobe, Japan). Novel PLT-F channel uses fluorescent light and stains platelets specifically with Oxazine Dye (Fluorescent Fluorocell). Bleeding complication has been collected in order to know if there is related to%IPF.
Results: Mean platelet count was 73.000 platelets/μL (range of 69-91) and IPF mean was 11% (2,5-23,4). Lab test Hemoglobin shows a mean of 95,17 g/L [range of 45-132] (in no-bleeding group was 105,8 g/L whereas in bleeding-group was 86,14 g/L p=0,0768) p=0,07. IPF% was <10% in 11, which means a 44% of the patients. 14 patients bleed during or after labor, 56% among all the patients in this study. Related to this group, 11 patients had IPF <10%; 3 of bleeding patients showed an IPF >10%. All pregnant women with an IPF <10% (11/11) bleed as a complication. Pregnant women with thrombocytopenia and a IPF <10% has a higher risk of bleeding during and/or after labor compared with pregnant women with a IFP>10% (Fisher 12,41, P<0,001). 5 (20,83%) patients among all of them were under treatment (earlier or during labor): 3 (12,5%) with steroids and 2 (8,33%) with other methods.

Summary/Conclusions: Thrombocytopenia is a potential risk of bleeding during the labor. A high IPF indicates either consumptive or recovering thrombocytopenic disorders, such as immune thrombocytopenic purpura, while low IPF is characteristic of bone marrow suppression states. Although not directly used in clinical decision making, the reference range is critical to the introduction of new parameters and the interpretation of laboratory results. Our results suggest that IPF is an easy laboratory parameter to be measured and a level <10% might be an independent bleeding factor which can be useful for detecting high risk pregnant patients. It should be corroborated in further studies.

PB2112

DOES EARLY RESPONSE TO FIRST LINE CORTICOSTEROID THERAPY PREDICT REQUIREMENT FOR SECOND LINE THERAPY IN IMMUNE THROMBOCYTOPENIA?

S. Kucukyurt Kaya[1,*], S. M. Bakanay[1], T. Hacibekiroglu[2], S. Akinci[2], M. Gündüz[2], S. Maral[2], A. Senturk Yikilmaz[1], I. Dilek[1]
[1]Department of Hematology, Ankara Yildirim Beyazit University, [2]Department of Hematology, Ankara Atatürk Training and Research Hospital, Ankara, Turkey

Background: Immune thrombocytopenia (ITP) is an acquired,immune-mediated disease that is characterized by increased destruction of platelets by autoantibodies. ITP is characterized by mucocutaneous bleeding. Rarely, life-threatening bleeding such as central nervous system bleeding can occur. Typically, patients have isolated thrombocytopenia. The diagnosis of ITP is one of exclusion. Corticosteroids are chosen as a first-line therapy for adult patients who require treatment. Responses to first line therapy with corticosteroids is about 80% with approximately 20% to 30% long term complete remission. Most patients finally relapse, requiring second-line therapy.
Aims: Our aim was to investigate potential effects of early platelet response to corticosteroid therapy on achieving long term complete remission.
Methods: We retrospectively evaluated 43 ITP patients who were followed-up at our institution. All patients' thrombocyte counts were below 30 x10^9/L at diagnosis. All patients received initially methylprednisolone(MP) 1 mg/kg/day. For patients who responded with platelet count ≥150 x10^9/L methylprednisolone was tapered over 3 months. Those who were unresponsive to MP or relapsed after a complete response, were treated with second line therapies that splenectomy or medical treatment agents. The platelet counts of the patients on day 0, 3 and 7 were evaluated by complete blood counts and were confirmed with peripheral smears examination. Effect of the platelet counts on day 3 and 7 were compared in terms of second line therapy requirement or not. A platelet count of >30x10^9/L on day 3 and >100x10^9/L on day 7 was considered as a complete response. Vaccination against encapsulated organisms was given and imaging was done to detect accessory spleen before splenectomy.
Results: Baseline characteristics of the cohort of 43 patients with an initial diagnosis of ITP are shown in Table 1. The mean age at diagnosis was 51 years (18-84) with female/male : 25/18. All patients presented with severe thrombocytopenia (platelet counts below 30.0x 10^9/L). Most patients presented with mucocutaneous bleeding (n=39), only three patients had genitourinary or gastrointestinal tract bleeding and one patient was asymptomatic. Bone marrow aspiration and biopsy was done in 14 (%32.6) patients due to various reasons mainly, failure to respond to ITP treatment (7 patients) and advanced age (7 patients). On third and seventh day of MP therapy, median platelet counts were 30x10^9/L (2,0 x10^9/L -150 x10^9/L) and 100 x10^9/L (1,0 x10^9/L-347 x10^9/L), respectively. When platelet counts on the 3rd and 7th day in each patient were compared, a significant association was found in correlation analysis (*p<0.05*). 21 patients (%48.8) required second line therapy which were splenectomy (76.2%) or medical treatment (23.8%). Medical therapy consisted of rituximab, eltrombopag, danazol. There was a statistically significant difference between the patients with platelet count below and over 30x10^9/L on 3rd day of the MP therapy in terms of requirement for a second line therapy. (*p=0.04*). On the other hand, when 7th day was taken into consideration, there was not a statistically significant difference when cut off was taken as 100 x10^9/L (*p=0.09*) or 50 x10^9/L (p=0.06).
Summary/Conclusions: In the era of novel therapies used as second line, predicting the prognosis of an ITP patient at diagnosis has been a challenge. If disease related factors at diagnosis can be identified, then patients can be rescued from long term corticosteroid exposure and its adverse effects. Early response of platelet counts after starting corticosteroids seems to predict long-term complete remission. Expanding the study population may contribute more to our findings.

PB2113

THE IMPACT OF FC GAMMA RECEPTOR IIA AND IIIA GENE POLYMORPHISMS ON THE THERAPEUTIC RESPONSE OF RITUXIMAB IN EGYPTIAN ADULT IMMUNE THROMBOCYTOPENIC PURPURA

H. Ellithy[1,*], S. Hassan[2], G. Shaheen[3], M. Mattar[4]
[1]Internal medicine- Hematology subdivision, [2]Internal medicine, [3]Clinical Pathology, [4]Internal medicine- Hematology subdivision, Kasr Al-ainy school of medicine- Cairo university, Cairo, Egypt

Background: Chronic primary immune thrombocytopenia (ITP) is an acquired autoimmune disease characterized by enhanced clearance of platelets and impaired platelet production. Corticosteroid is the ministry line of treatment of ITP, patients who fail to respond to steroid (steroid resistant) or who relapse (steroid dependant) face the options of treatment with second line including anti CD-20 monoclonal antibody rituximab. Rituximab is a chimeric IgG1 monoclonal antibody (mAbs). The major mechanism of action of rituximab is the antibody-dependent cellular cytotoxicity (ADCC), ADCC effectiveness is influenced by process of activation of effector cells via their immunoglobulin G fragment C receptors (FcγRs). Fcγ receptors show distinct affinity to bind to IgG subtype specificities. Differential response to rituximab has been reported to correlate with specific polymorphisms in two of FcγR genes: FcγRIIa (H131R) and FcγRIIIa (V158F) in some diseases.
Aims: To clarify the effect of FcγRIIa-131 R/H and FcγRIIIa-158 V/F genes polymorphism on the response to rituximab in ITP patients.
Methods: We studied the frequency of the FCγRIIa (H131R) and FcγRIIIa (V158F) gene polymorphisms, in 100 chronic ITP patients; divided into 2 equal groups, first group received rituximb (375 mg /m2 per dose weekly for four weeks) and the other group received non-mabthera second line therapy. A polymerase chain reaction-restriction fragment length polymorphism assay [PCR-RFLP] was used to detect FcγRIIa-131 R/H and FcγRIIIa-158 V/F genes polymorphism. Evaluation of platelets counts was assessed initially before starting second line therapy then weekly for 3 months. At the end of third month the response to second line therapy was considered according to the following criteria; complete response (CR) PLT >100×10^9/L., partial Response (R), PLT=30-100×10^9/L , no response (NR), PLT<30×10^9/L.
Results: Regarding FcγRIIa gene (H131R) polymorphism distribution in the 100 patients; 28 patients (28%) had wild HH genotype, 41 patients (41%) have heterozygous genotype (HR) and 31patients (31%) have homozygous mutant genotype (RR). In our study, the 100 ITP patients included showed wild type of FcγRIIIa (V158F) gene polymorphism. By the end of month 3 of the second line therapy, 43/100 patients (43%) achieved CR, 37/100 patients (37%) achieved PR and 20/100 patients (20%) achieved NR. Among the 50 patients who treated with Rituximab; 18 patients (36%) achieved CR, 19 patients (38%) achieved PR and 13 patients (26%) achieved NR. Out of the 18 patients who achieved CR, 8/18 patients (44.4%) carried FcγRIIa RR genotype and 7/ 18 patients (38.9%) carried FcγRIIa HR, compared to 3/18 patients (16.7%) carried FcγRIIa HH genotype. However it was not statistically significant. Among the 13 patients who achieved NR, lowest rate was patients carried FcγRIIa RR genotype 3/13 patients (23.1%) compared to HR (38.5%) and HH (38.5%) genotypes. However it is not statistically significant. The mean value of platelet count at end of week 1, Week 2 and Week 3 of rituximab therapy show statistically significant differences (P value 0.001) being higher in patients achieved CR than who achieved PR or NR.
Summary/Conclusions: The higher platelet count achieved early (end of week 1, 2, and 3) after rituximab is suggestive for a better response later (at end of M3). FcγRIIa RR genotype is predictive for better response to rituximab in ITP patients.

PB2114

IMMUNE THROMBOCYTOPENIA. EGYPTIAN EXPERIENCE WITH STUDY OF IL-17,TGFB, IL-35 AND IL-12 CYTOKINES IN CHRONIC AND PERSISTENT IMMUNE THROMBOCYTOPENIA PATIENTS

N. El Husseiny[1,*]
[1]kasr al aini hospital, cairo, Egypt

Background: The role of T cells in the pathophysiology of immune thrombocytopenia (ITP) is heterogeneous and complex.It has been studied in active and reactive ITP but not to same extend in chronic and persistent type.
Aims: In this study we review the demographic features of 150 immune thrombocytopenic Egyptian patients and for cases who were chronic and persistent with negative both autoimmune screen and virology for hepatitis B and C
Methods: We measured IL-12, IL-35, IL-17 and TGF-β by ELISA to assess role of subtypes of T cells in the pathophysiology of ITP.
Results: Our results revealed Chronic and persistent cases who fulfilled the criteria for cytokine assay were 45 cases with a mean (± SD) age of 31.60±8.78 years. Thirty two patients were presented by skin manifestations (71.1%).Eight patients presented with mucous bleeding (17.8%) and five patients presented by combined skin and mucous membrane bleeding (11.1%). Comparison between the cases studied and control groups revealed statistically significant lower platelet count in cases rather than the control. While the four measured cytokines were statistically significant higher in cases rather than the control. Correlation between platelet count and the level of cytokines was statistically insignificant. All cases were under treatment by low dose corticosteroid in addition to another immunesuppression medication. No correlation between measured cytokines and platelet count.
Summary/Conclusions: The higher expression of IL-12 and IL-35 is due to persistently higher TH1 activity which explain continuity of the disease.while the higher expression of Treg cytokines (IL-17 and TGF-B) may be explained by effect of immune suppression use or up regulation of their receptors on Treg cells which have resistance to their activity. In chronic ITP, the level of Tcell cytokines can't predict the course of disease.

PB2115

SWITCH OF TPO-MIMETICS IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA: FLORENCE MONOCENTRIC EXPERIENCE

C. Biagiotti[1,*], V. Carrai[1], F. Bacchiarri[1], A. Bosi[1]
[1]Hematology, Careggi Hospital, Florence, Italy

Background: Primary immune thrombocytopenia (ITP) is an immune-mediated condition characterized by isolated thrombocytopenia, with peripheral blood platelet count of <100.000/µl in the absence of an identifiable underlying cause of thrombocytopenia. Clinical studies in patients with ITP demonstrated that thrombopoietin (TPO) mimetics increase platelet production and can outpace platelet destruction.
Aims: We evalueted patients treated with both TPO-mimetics.
Methods: From November 2008 and February 2017, 65 patients were treated with TPO-mimetics with a median follow up of 29 months (1-96): 39 patients underwent therapy with Romiplostim and 26 to Eltrombopag. In our study we evaluated 18 patients who received both therapies: among patients treated at first with Romiplostim, 10 patients (9F; 1 M) switched to Eltrombopag and 8 patients (3 M; 5 F) switched from Eltrombopag to Romiplostim. In the group of 10 patients treated at first with Romiplostim, 5 patients started Eltrombopag because were no responders, 3 for loss of response and 2 patients because of adverse events. In the group of 8 patients at first treated with Eltrombopag, 4 patients didn't obtain any response with Eltrombopag and switched to Romiplostim, 1 patient underwent to Romiplostim for loss of response and 3 patients because of adverse events.
Results: Among patients switched from Romiplostim to Eltrombopag, 2 achieved complete response, 4 response and 4 were no responders; among patients switched from Eltrombopag to Romiplostim, 4 obtained complete response, 3 response, 1 was no responder.
Summary/Conclusions: Romiplostim and Eltrombopag stimulate the TPO-R but have different mechanisms of action, therefore, in our limited experience switching from one thrombopoietic receptoragonist to the other could be beneficial in clinical practice for patients with severe chronic immune thrombocytopenia who failed to respond or experienced adverse events to the first treatment.

PB2116

COEXISTENCE OF GLANZMANN'S THROMBASTHENIA AND MAPLE SYRUP URINE DISEASE: IMPLICATIONS FOR HEMOSTATIC MANAGEMENT

M. Elshinawy[1,*], A. Alrawas[2], Y. Wali[2]
[1]Pediatric Hematology, SQUH, Alexandria University, Muscat, Oman, Egypt, [2]Pediatric Hematology, SULTAN QABOOS UNIVERSITY HOSPITAL, Muscat, Oman

Background: In Oman, autosomal recessive disorders are relatively commoner than western communities due to the high prevalence of inter-tribal marriage. Unfortunately, some patients have got more than one autosomal recessive genetic disorder, owing to complex consanguinity which might further complicate proper management plans.
Aims: To report an interesting case of combined Glanzmann's thrombasthenia and MSUD, and to review the existing data of platelet function disorders in Oman.
Methods: Case report and retrospective data analysis of all cases with confirmed or suspected platelet function disorders in Pediatric Hematology Unit, Sultan Qaboos University Hospital, Muscat, Oman from January 2006 till December 2016.
Results: We report a 4 year-old girl who is a known case of MSUD. Her parents are double first cousins (from both maternal and paternal sides). At the age of 3 months, she required Gastrostomy tube (G-tube) insertion. Preoperatively, full blood count and coagulation screen were perfectly normal. Unfortunately, she developed profuse bleeding at the site of G-tube insertion, followed by massive hematemesis. The patient received multiple blood products, but bleeding didn't stop. As an emergency measure, recombinant activated factor VII (rFVIIa) was given and resulted in cessation of bleeding. Platelet aggregation studies revealed defective aggregation with ADP, arachidonic acid, collagen and epinephrine which is consistent with Glanzmann's thrombasthenia. The diagnosis was further confirmed by platelet flow cytometry which showed no activity with CD41 and CD61, indicating absent GpIIb/IIIa complex. The patient experienced a severe bleeding phenotype, which is further complicated by multiple coexisting factors, including the recurrent episodes of metabolic crises which provoked worsening of platelet function, the development of platelet refractoriness at the age of 1 year , and the need for recurrent invasive procedures such as G-tube and central line insertion. Currently, the bleeding episodes are managed by rFVIIa at a dose of 120-180 µg /kg/dose. Excluding von Willebrand disease, we have 38 cases of confirmed or suspected platelet function disorders in our center, including 15 cases with Glanzmann's thrombasthenia, 7 cases with Bernard-Soulier syndrome, 5 cases with May–Hegglin anomaly and 11 cases of suspected, yet unconfirmed platelet storage pool deficiency.
Summary/Conclusions: In conclusion, children with platelet function disorders still have plenty of unmet needs, ranging from deficient accurate diagnostic facilities to the lack of agreed upon consensus management guidelines. The coexistence of another hereditary disorder may result in mutual management difficulties of both diseases. In developing countries, proper registry is needed to establish optimum care of such rare disorders.

PB2117

ASSESSMENT OF PLATELET REACTIVITY TO ASPIRIN AND CLOPIDOGREL WITH POINT-OF-CARE VERIFYNOW® ASSAY AND TWO ALTERNATIVE METHODS IN PATIENTS WITH CEREBRAL ANEURYSMS TREATED WITH ENDOVASCULAR PROCEDURES

D. Velasco-Rodríguez[1,*], R. Vidal[1], S. Martín Herrero[1], T. Castaño Bonilla[1], A. García Raso[2], M. Martínez-Galdámez[3], P. Llamas[1]
[1]Hematology, [2]Health Care Institute, [3]Neuroradiology, Fundación Jiménez Díaz, Madrid, Spain

Background: Stent thrombosis and hemorrhage are the main complications after endovascular procedures for cerebral aneurysm treatment. Identifying an optimal pre-procedure response to antiplatelet therapy is essential to guarantee a successful result. A high variability in the individual responses to the antiagregant effect of aspirin and, specially, with clopidogrel has been reported. The VerifyNow® System (Accumetrics, San Diego, CA, USA) performs a turbidimetric-based optical detection of induced platelet aggregation in response to major antiplatelet agents (P2Y12 inhibitors, aspirin, GP IIb/IIIa inhibitors).
Aims: 1) To measure the antiplatelet effect of aspirin and clopidogrel with the point-of-care VerifyNow® assay in patients with brain aneurysms before undergoing endovascular treatment. 2) To compare the results with two alternative methods: impedance aggregometry. and PFA-100.
Methods: 38 patients with cerebral aneurysms, scheduled for elective endovascular procedure, were included in the study. All of them had started taking aspirin at a dose of 100 mg daily and clopidogrel at a dose of 75 mg daily 7 to 10 days before testing aspirin and clopidogrel sensitivity. The following functional tests were performed in all of them before the procedure: 1) VerifyNow® assay: Aspirin Reaction Units (ARU) <550 and P2Y12 Unit Reaction Units (PRU) <208 were considered to be good response to aspirin and clopidogrel respectively. PRU <85 was considered hyper-response to clopidogrel. 2) Impedance aggregometry from whole blood (Multiplate® analyzer, Roche Diagnostics, Mannheim, Germany): arachidonic acid (AA), adenosine diphosphate (ADP) and thrombin receptor activating peptide (TRAP) were used as agonists. TRAP was used to determine baseline platelet function. Aggregation with AA <40 U and aggregation with ADP <47 U were considered good responses to aspirin and clopidogrel respectively. 3) PFA-100: an overall assessment of platelet function was performed using epinephrine-collagen (COL/EPI) and ADP-collagen (COL/ADP) cartridges. Although COL/ADP is not an appropriate method to evaluate the effect of tienopyridines, we performed it to analyze whether hyper-responders to clopidogrel detected by VerifyNow® were also identified with PFA-100.
Results: The results of platelet function testing with three different methods are summarized in Table 1. None of the patients showed thrombocytopenia. Good response to aspirin was observed in 84.21%, 97.36% and 93.75% of the patients using VerifyNow®, Multiplate® and PFA-100 respectively. Good response to clopidogrel was detected in 86.84%, 38.88% and 62.5% of the patients using VerifyNow®, Multiplate® and PFA-100 respectively. VerifyNow® identified 6 (15.78%) aspirin-resistant patients. However, PFA-100 and Multiplate® assays showed a significant aspirin-mediated platelet dysfunction in 5 of them. Low response to clopidogrel was detected by Verifynow® in 5 (13.15%) patients consistent with Multiplate® results. Verifynow® identified 10 patients with excessive response, but only 2 of these results were reproduced by Multiplate® or COL/ADP. Multiplate® detected 19 patients (50%) with suboptimal response to clopidogrel, although these results did not correlate with those obtained by VerifyNow®.

Table 1.

35	220000	394	90	285	300	31	103	159
36	191000	384	185	283	110	31	50	133
37	344000	448	149					
38	240000	527	109	150	300	15	33	98

Summary/Conclusions: The effect of aspirin can be accurately measured by platelet aggregation and PFA-100 (with COL/EPI); however, VerifyNow® seems to identify a higher number of poor responders. Multiplate® assay using only

ADP is not good enough to detect clopidogrel-mediated platelet dysfunction since it is not specific for the P2Y12 receptor. The addition of PGE1 to the ADP test may increase its sensitivity. VerifyNow® assay seems to overestimate the effect of clopidogrel, since hyper-response data are not reproduced by other techniques. According to our results, a high interindividual variability in response to clopidogrel is observed.

PB2118

THROMBOPOIETIN-RECEPTOR AGONISTS IN ITP - EXPERIENCE OF A CENTER

M. J. Teles[1,*], M. Gomes[2], F. Ferreira[2], J. E. Guimaraes[2]
[1]Clinical Pathology, [2]Clinical Hemathology, Sao Joao Hospital Centre, Porto, Portugal

Background: Thrombopoietin-receptor agonists (TRA), romiplostim and eltrombopag, are part of the treatment of chronic immune thrombocytopenia (ITP), resistant to first line therapy (corticosteroids and/or immunoglobulins) and with a significant bleeding risk. Both are approved for adult patients, but only eltrombopag was approved for pediatric use. When used before splenectomy, these treatments may serve as a bridge for surgery or even postpone/avoid the procedure.
Aims: In this report, we aim to evaluate the response to TRA treatment in patients with ITP and associated side effects in our center.
Methods: Inclusion criteria: patients with ITP resistant to first line treatment. Patients characteristics, response to TRA, clinical evolution and adverse effects were evaluated by retrospective analysis.
Results: Thirty-eight patients with ITP were included: 31.4% (12) were male and the median age at diagnosis was 38 years. 44.7% (17) had relapsed/resistant disease after splenectomy and 13.2% (5) were treated with a TRA as a bridge for this procedure. Sixteen (42.1%) of ITP patients were treated with romiplostim: 12 patients (75%) had a response to treatment, and 4 (25%) were resistant. In 11 of these patients, romiplostim was replaced by eltrombopag, either because of resistant disease, or more convenient administration (oral therapy). Thirty-three (86.8%) patients were treated with eltrombopag (5 pediatric cases): 27 patients (81.8%) responded while 6 patients had resistant disease (3 of these were HIV positive). The response rate was higher in patients with previous splenectomy (91.7% with romiplostim and 92.9% with eltrombopag) compared to those with no previous splenectomy (25% with romiplostim and 73.7% with eltrombopag). Six patients maintained response after treatment suspension (5 treated with eltrombopag and 1 treated with romiplostim). Generally, both treatments were well tolerated, with only one case of eltrombopag suspension because of a thromboembolic event.
Summary/Conclusions: In the current study, both TRA were effective in the treatment of ITP resistant to several lines of treatment, with similar response rates. As described in the literature, the response rate was higher in patients with previous splenectomy, and some cases maintained response after treatment suspension. The toxicity profile was acceptable. However, there are some concerns about their safety in long term therapy, namely the development of myelofibrosis, cytogenetic abnormalities and malignant evolution. Consequently, there is an urgent need for prospective studies to define the optimal period of treatment and surveillance, especially in pediatric patients. In our center, the median time of treatment with eltrombopag for all patients was 5.5 months (range between 1 to 34 months) and with romiplostim was 12 months (range between 1.5 to 85 months). The duration of treatment with eltrombopag in children and adolescents was around 6 months.

PB2119

THE EVALUATION OF REACTIVE OXYGEN SPECIES IN ESSENTIAL THROMBOCYTEMIA AND CORRELATION WITH JAK2V617F MUTATION

M.-A. Gaman[1,*], C. Moisa[2], A. M. Gaman[3,4]
[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, [2]Emergency County Hospital Slatina, Slatina, [3]Hematology, Filantropia City Hospital, [4]Pathophysiology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background: Essential thrombocytemia (ET) is a clonal disorder of the hematopoietic stem cells characterized by excessive myeloid proliferation, with predominant megakaryocytic expansion and a potential of transformation to acute myeloid leukemia. 50 to 60% of ET cases present a JAK2V617F mutation. 5% to 10% of JAK2V16F negative ET patients have MPL mutations at codon 515 and 50% to 70% of ET patients with non-mutated JAK2 and MPL (double-negative) carry mutations at exon 9 of CALR. Genomic instability in ET may be associated with an increased level of reactive oxygen species (ROS) which also leads to DNA damage. Hematopoietic stem cells of JAK2V617F positive murine models have higher ROS levels than found in normal mice (Marty et al, 2013).
Aims: To evaluate ROS levels in patients with ET and to observe if JAK2V617F positive cases associate higher ROS levels compared to patients without JAK2V617F mutation.
Methods: We studied 23 patients with ET admitted to the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, diagnosed with ET according to the 2008 revised WHO criteria (informed consent obtained). All analysis were performed after diagnosis and before the start of therapy. The JAK2V617F mutation was detected by allele specific polymerase chain reaction (PCR) testing. ROS levels were detected by flow-cytometry using a Cy Flow Space Sysmex flow-cytometer and a DCFDA Cellular ROS Detection Assay Kit. Studied parameters were compared both to healthy controls and to each other. Exclusion criteria were presence of any condition associated with an increased oxidative status (alcohol consumption, smoking, diabetes mellitus, hyperlipidemia, chronic renal failure, human immunodeficiency, cirrhosis, and active infection), use of antioxidants or iron supplementation. Data analysis was performed using Flow Max software. The differences between the two groups were assessed using the Student T-test and a p-value of less than 0.05 was considered statistically significant.
Results: The study group involved 12 females and 11 males, with a median age of 48 years. All patients had increased ROS levels at diagnosis compared to healthy controls. Eleven patients had JAK2V617F mutation and twelve were JAK2V617F mutation negative. Significantly higher ROS levels were found in JAK2-positive patients compared to JAK2-negative patients.
Summary/Conclusions: In our study, patients with ET had increased ROS levels. Cases with JAK2V617F mutation associated higher ROS levels compared to those without JAK2V617F mutation. In our future research, we will focus on the follow-up of these patients for a period of four years and we will try to observe if increased ROS levels enhanced genomic instability and transformation to acute myeloid leukemia.

PB2120

VARIATIONS IN PARAMETRES OF PLATELET COUNT AND PLATELET VOLUME ACCORDING TO GESTATIONAL AGE

S. Akarsu[1,*], M. Aydin[1], E. Taşkın[1]
[1]Fırat Üniversitesi Tıp Fakültesi, Elazığ, Fırat Üniversitesi Tıp Fakültesi, Elazığ, Elazığ, Turkey

Background: Reference ranges of haematological parameters in preterm infants are limited.
In hematological evaluation not only platelet (PLT) counts but also 3 important platelet volume parametres (mean platelet volume [MPV], platelet distribution width [PDW], plateletcrit [PCT]) are also taken into consideration.
Aims: We wanted to investigate the impact of gestational age by determining variations in platelet volume parametres according to gestational weeks.
Methods: Medical records were prospectively reviewed in preterm infants admitted to Firat University Hospital from January 2001 to December 2007. Study group consisted of only one-hour-old newborns delivered in the clinics of Department of Gynecology, and Obstetrics of our hospital. The exclusion criteria included those with maternal history of antepartum haemorrhage, chorioamnionitis, fever, sepsis, preeclampsia and hypertension; and perinatal history of twin-to-twin transfusion syndrome, feto-maternal transfusion, injury and infection. A hundred and ninety-three newborns with apparent health problems were excluded from our study. Study group comprised 398 preterm infants born between 26-37 gestational weeks, and 63 healthy term (38 gestational weeks) infants. Blood samples from all cases were obtained within the first hours after birth. Blood samples were placed into tubes with EDTA, and analyzed in ADVIA 120® (Japan) hematology analyzer using suitable kits. Data were expressed as mean±standard deviation. Platelet counts, and volume were indicated for each gestational week, and groups of 24-31, 32-36, 37, and 38 weeks. One-way analysis of variance (ANOVA) was used for statistical analysis, and $p<0.05$ was accepted as the level of statistical significance.We established the reference ranges of platelet and platelet index in Turkish preterm and term infants. Platelet counts, and platelet volumes continually change as gestational age increases. Increases in platelet counts, and PCT, while decreases in MPV and PDW were detected. The gestational age-related changes in PLT patterns may reflect maturation of platelet regulation.
Results: Platelet counts increased beginning from the 26^{th} up to 28^{th}weeks. They did not change between 29^{th} and 33^{rd}weeks, while their levels rised again conspicuosly between 34^{th} and 37^{th} weeks. At 38^{th} week a dramatic increase occurred at 38^{th} week. MPV, and PDW values slightly decreased, while PCT values increased dependent on the gestational age. When we classified newborns in groups of 24^{th}-31^{th}, 32^{th}-36^{th}, and 37^{th}, and 38^{th} weeks, prominent, and statistically significant variations were observed between groups.
Summary/Conclusions: We established the reference ranges of platelet and platelet index in Turkish preterm and term infants. Platelet counts, and platelet volumes continually change as gestational age increases. Increases in platelet counts, and PCT, while decreases in MPV and PDW were detected. The gestational age-related changes in PLT patterns may reflect maturation of platelet regulation.

RISK OF LUPUS AFTER PRIMARY IMMUNE THROMBOCYTOPENIC PURPURA: A 14 YEAR SINGLE CENTER EXPERIENCE

M. Ayesh (Haj Yousef)[1,*], K. Alawneh[1], Y. Khader[2], F. Malkawi[3]
[1]Medicine, [2]Public Health, Jordan University of Science and Technology, [3]Department of Laboratory , Kng Abdullah University Hospital, Irbid, Jordan

Background: Primary immune thrombocytopenia (ITP) is an autoimmune disorder characterized by immune-mediated platelet destruction and suppressed platelet production. ITP may occur concurrently or precede the occurrence of SLE, which would have great diagnostic significance. ITP may also be the first early sign of the disease. Few studies have addressed the risk of systemic lupus erythematosus (SLE) after ITP.
Aims: To estimate the risk of SLE after ITP in adult Jordanian patients
Methods: All patients diagnosed with ITP and with a platelet count <100×10^9/L, between September 2002 and January 2017 were included in the study. Patients were retrospectively reviewed for diagnosis of SLE, and inclusion criteria included only those patients who had initial ANA screen at the time of the first presentation of ITP .All patents with the diagnosis of SLE at the time and before the presentation of primary ITP were excluded from the study.
Results: This study included a total of 58 patients (43 females and 15 males) who were followed up for a period of 14 years. Their age at the baseline ranged from 16 to 65 years with a mean (SD) of 31.2 (13.3). ANA was positive in 11 (19.0%) patients. Over the period of follow up, 9 (15.5%) patients developed lupus. The incidence was 13.3% among males and 16.3% among females, with no significant difference (p-value=0.786). There was significant association between ANA and lupus in both genders. Only one patient with negative ANA and 81.8% of patients with positive ANA developed lupus (P<0.005.
Summary/Conclusions: SLE developed in patients with primary ITP in with initial positive ANA titer at presentation. The results suggest that patients with initial positive ANA are at risk for development SLE. Thus, follow up after primary ITP diagnosis with positive ANA titer is of great importance as the risk of SLE is significant

PB2122

TREATMENT OF REFRACTORY IMMUNE THROMBOCYTOPENIA WITH THROMBOPOIETIN RECEPTOR AGONISTS: OUR EXPERIENCE IN CHILDHOOD

J. Zanabili Al-Sibai[1,*], T. Arias Fernández[1], M.P. Palomo Moraleda[1], L.R. Morais Bras[1], C. Castañón Fernández[1], L.F. Ávila Idrovo[1], A. Solé Magdalena[1], S. González Muñiz[1], M.Á. Fernandez Rodríguez[1]
[1]Hematology, HUCA, Oviedo, Spain

Background: Immune thrombocytopenia (ITP) is an autoimmune disease in which antibodies develop against platelets (plts) and dysregulation of cellular immunity result in premature destruction of plts and impaired plt production. For most affected children, ITP is a self-limiting disease. Approximately, 10% of all ITP patients eventually develop refractory ITP (RITP). Thrombopoietin receptor agonists (TPO-RA) stimulate thrombopoiesis and are an alternative to Rituximab (Rtx) and splenectomy.
Aims: We present 3 different children with RITP treated with TPO-RA.

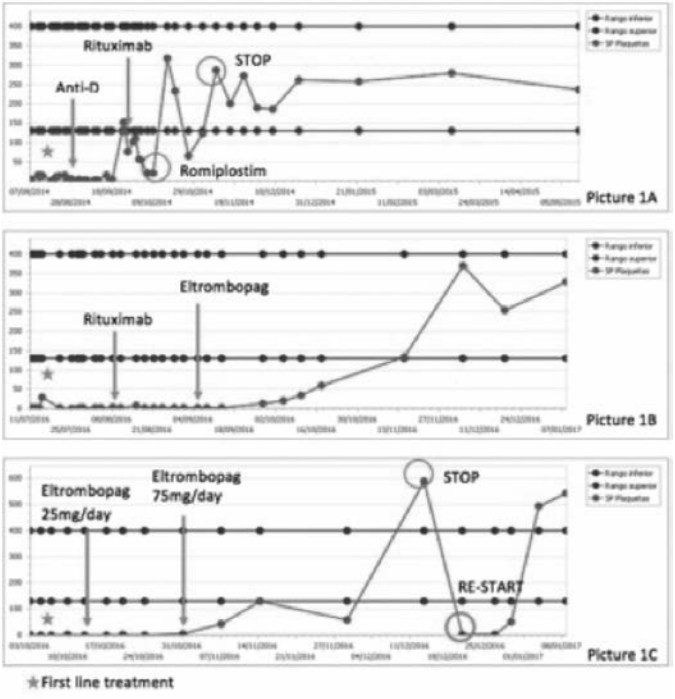

Figure 1.

Methods: CASE 1. A 5-year-old girl admitted to the hospital due to ITP with mucocutaneous bleeding. She was refractory to corticoids, immune globulin (Ig) and anti-D Ig. Rtx was started. After the 3rd dose, she responded temporarily along with fever, renal insufficiency and arterial hypertension, probably related to Ig A deficiency, not previously diagnosed. Romiplostim was indicated, reaching complete remission after 2 doses and it was stopped after the 4th dose, without any adverse reaction. Nowadays, plt count remains within normal limits (Figure 1A). CASE 2. A 5-year-old boy was diagnosed of ITP with cutaneous bleeding. He received treatment with prednisone and Ig with short response. Rtx was indicated; after 4th dose, severe thrombocytopenia and cutaneous bleeding persisted. Eltrombopag was started with response after 6 weeks of treatment (Figure 1B) and bleeding symptoms recovery. CASE 3. A 4-years-old boy with RITP was referred to our hospital. We decided to initiate treatment with Eltrombopag. He developed response after 4 weeks of treatment with a dose of 75mg/24h. Six weeks later, he presented 600,000plts/µL, so the drug was stopped. We observed a quick descent in plts levels and Eltrombopag was restarted with progressive response (Figure 1C).
Results: In all cases, splenectomy was avoided due to long-term risk of sepsis, as well as immunosuppressive agents like RTX in 3rd case. In 1st case, TPO-RA was able to stop with sustained response as described in some publications.
Summary/Conclusions: In our experience, TPO-RA appear to be efficacy and well tolerated in children.

PB2123

INVESTIGATION OF PLATELET FUNCTIONS IN PSEUDOTHROMBOCYTOPENIA

B. Onec[1,*], S. Cesur[2], K. Onec[2], E. Caliskan[3], S. Cangur[4]
[1]Hematology, [2]Internal Medicine, [3]Medical Microbiology, [4]Biostatistics, Duzce University Faculty Of Medicine, Duzce, Turkey

Background: Pseudothrombocytopenia (pseudoTCP)), is incorrectly detection of low platelet counts in automatic blood counter devices and is most frequently caused by ethylene diamine tetra-aseticacid (EDTA) induced platelet clumping and *in vitro* agglutination. Therefore, pseudoTCP which accounts 15-30 of thrombocytopenic admissions, actually is not associated with a bleeding tendency. This situation may be detected with a careful investigation of peripheral blood smears (PBS) by experienced clinicians but in centers which does not have these facilities; misleading of worried patients through advanced centers or even unnecessery treatments with steroids and platelet transfusions often occurs.
Aims: In theory, formation of platelet clusters in the presence of EDTA requires functional adhesion molecules, so platelet adhesion and aggregation tests are expected to be in normal range. We aimed to investigate the capacity of simple platelet function analizers for making the distinction between pseudo TCP and real thrombocytopenia.
Methods: Platelet functions were measured as collagen-ADP and collagen-epinephrine closure times (ColADP and ColEPI) by Platelet Function Analyzer (PFA-200™) for all patients who are referred to our clinic as thrombocytopenia (TCP, plt <150 x10^3/µL) and value of this new method for determining peseudoTCP is compared with PBS which is accepted as the gold standard by using Receiver Operating Characteristic (ROC) curve analysis. PFA-200 system closure time is expected to be longer in true thrombocytopenia and normal in pseudoTCP, but there is no study investigated this system for this purpose. Descriptive analyses were presented using means ±standard deviations for normally distributed variables or median and interquartile range (IQR) for nonparametric continuous variables. An overall p-value of less than 0.05 was considered to show a statistically significant result. This study is supported by Duzce University with project number of 2015.04.03.370 and these are preliminary results.
Results: We included 59 patients who were referred to our clinic with thrombocytopenia (TCP, Plt<150 x10^3/µL) and 11 healthy controls (Plt>150 x103/µL). Median age was 54 (IQR:37-68) for thrombocytopenic subjects and 37 (%63) of them were female. Median Plt count was 61 x103/µL (IQR:30-90) in TCP group but WBC and Hb were not different from control subjects. Subjects referred with TCP were grouped with PBS as pseudoTCP and real-TCP. There was no difference in terms of Plt, MPV, PCT, WBC or Hb between these groups but age was younger (median age 46 *vs* 62, p<0.05) and PDW was higher in pseudoTCP group (med 17.6 *vs* 16.8, p<0.01). ColEPI and ColADP measures were significantly lower (med 125 *vs* 287 for ColEPI, med 84 *vs* 224 for ColADP, p<0.001 for both) at pseudoTCP group. The capacity of ColEPI and ColADP values in predicting pseudoTCP were analyzed using ROC curve analysis. We found that, when the manufacturer's recommended cut-off value (150 s) was used, the sensitivity and specificity were 74.4% and 95%, with overall accuracy of 81.4% for ColEPI (AUC 0.813, SD:0.061, p<0.001,%95CI: 0.694-0.933). Similarly sensitivity and specificity were 79.5%, and 95%, with overall accuracy of 84.7% for ColADP using manufacturer's cut-off value of 100 s (AUC 0.878, SD:0.055, p<0.001,%95CI: 0.770-0.986).
Summary/Conclusions: We concluded that, running PFA tests for everybody with thrombocytopenic counts, could be used for differentiate pseudoTCP and realTCP in centers which does not have conditions for proper BS. Especially long closure times excludes pseudoTCP with a high specificity and could make clinicians quick decisions for further investigations.

PB2124

MANAGEMENT OF ADULT CHRONIC IMMUNE THROMBOCYTOPENIA. SINGLE CENTER EXPERIENCE

C. Ionita[1], I. Ionita[1], D. Calamar-Popovici[1], D. N. Oros[1], M. Iordache[1], M. Ionita[1], I. Pascu[1], M. Ifrose[1], H. Ionita[1,*]
[1]UMF "Victor Babes" Timisoara, Timisoara, Romania

Background: The investigation and management of patients with Chronic immune thrombocytopenic purpura (ITP) varies widely. Although many treatments have been recommended for ITP, there are no evidence-bassed recommendations for when different treatments should be used, or when any treatment should be used rather than managing a patient by observation alone.
Aims: To evaluate the treatment of ITP patients in Departament of Hematology, County Hospital, Timişoara.
Methods: A retrospective study for 350 ITP patients was performed. Patients demographics, medical history, current treatments and side effects, were abstracted from the patient's medical charts for the 15 months prior to their most recent visit.
Results: The mean age was 45.6 years with 58% women and 42% men. Median time from the diagnosis of ITP to the start of the observational period was 23 months. Regardless of the presence of bleeding symptoms, for majority of patients we started treatment based on plateled count. Treatment was considered when platelet counts are less than $20x10^9$/L in patients without bleeding, and less than $30x10^9$/L in patients with bleeding. Prior to the observational period, 36% of patients had been splenectomized and the most reported treatment was corticosteroids. During the observational period, 72% of all patients were treated. The most frequent reasons given for treatment were platelet count (58%), followed by bleeding symptoms (42%). Corticosteroids represented 52% of treatments, followed by IVIg (20%), azathioprine (12%) rituximab and 8% Nplate. Splenectomies (8% of patients) and platelet transfusions (27% of patients) were performed during the observational period. In the patient survey, 52% of participants were 60 years of age or older and the duration of disease was more than 10 years in 43% of patients. The minimum platelet counts were less than $10x10^9$/L in 49% of patients. The most common symptoms of ITP was fatigue (45%). Approximately 60% of patients reported at least one side effect associated with ITP treatment. The side effects were most frequently associated with corticosteroid use (43%). Overall, 40% of patients required hospitalization. Mean duration of hospitalization was 13,5 days.
Summary/Conclusions: The retrospective study of 350 patients provides the results of treatment practices in our country. It showed that bleeding symptoms remained quite frequent among patients with chronic ITP. Corticosteroids were the most widely used treatment.

PB2125

IMMUNOLOGICAL THROMBOCYTOPENIC PURPURA AND PREGNANCY: A RETROSPECTIVE STUDY OF 89 PREGNANCIES IN 59 PATIENTS

H. Brahimi[1,*], S. Taoussi[1], Z. Bouchetara[1], K. Rekrouk[1], M. T. Abad[1]
[1]Hematoloy, EHS ELCC CAC, Blida, Algeria

Background: Immunological thrombocytopenic purpura (ITP) occurs for about 1 case for 1000 pregnancies. The risk of onset, aggravation or relapse of ITP during pregnancy is not clearly established.
Aims: The aim is to describe the prevailing ITP progression profile in pregnant women and to evaluate the risk of neonatal thrombocytopenia in two situations, when ITP was known before pregnancy and when ITP was discovered for first time during pregnancy.
Methods: It is a retrospective study carried out in the hematology department of CAC Blida, Algeria, between 1993 and 2016. All patients (pts) who had a pre-pregnancy ITP or thrombocytopenia during pregnancy attached to an ITP were included.
Results: The development of 89 pregnancies (PG), including two twins, occurred in 59 women was analyzed. There were one PG in 40 pts, 2 PG: 13 pts, 3 PG : 5 cases, 4 PG : 1 case and 5 PG : 1 case. Of the 59 pts: in 42 cases it was a history of ITP before pregnancy (group 1: G1) with a history of splenectomy in 9 patients, and in 17 cases it was ITP discovered on the occasion of Pregnancy (group 2: G2). The average age at diagnosis=26.7 years (7-44) and that at delivery=30.4 years (19-44). The mean platelet count at diagnosis: G1: 34000 / µL , G2: 47000 / µL. In the first group (G1): At the beginning of pregnancy the ITP was chronic in 30 cases, newly diagnosed in 1 case, persistent in 2 cases and transient cured in 7 cases; treatments previously received were: corticosteroid therapy (n=34), splenectomy (n=9), Danazol (n=1), cyclosporine in 1 case and cyclophosphamide in 1 case, abstention in 7 pts, 2 of whom required corticosteroids during pregnancy. The status of the ITP at the beginning of each pregnancy was: out of treatment (n=8), corticosteroid dependence (n=5), non-response (n=7), PR (n=11), CR (n=24).In the second group (G2): the discovery of thrombocytopenia was in the first trimester (T) in 4 cases, in the second T in 6 cases and in the third T in 7 cases; 17 pts had platelet counts <80000 / µL and were included due to the persistence or even worsening and / or necessity to resort to treatment of thrombocytopenia after delivery. In both groups: in 26 pts (G1:16; G2: 10)variable dose and duration treatment were required during pregnancy; at delivery, 19 patients needed a treatment, out of them, a bolus of corticosteroids (n=11)+transfusion of platelets (n=4), immunoglobulins in 4 cases and transfusion of platelets alone in 4 cases. At birth, thrombocytopenia was observed in 40 pregnancies (50.6%): platelets <30000 / µL (n=7), between 31000 and 50000 /µL (n=13), between 51000 and 100000/µ (n=20), between 100000 and 150000/µl in 2 cases. All pregnancies were completed: 14 by caesarean section, one for thrombocytopenia, with an average platelet count=95000 /µL and 75 by natural delivery with a mean platelet count=100000 / µL with 4 deaths born, one anencephaly and 88 newborns No hemorrhagic syndrome was observed in pregnancy; two postpartum hemorrhages were seen in G2 group. Eleven newborns (5 in G1 and 6 in G2) were thrombocytopenic with platelet count <20000/µL in 4 cases; between 20000 and 50000/µL in 7 cases; neonatal thrombocytopenia occurred during the first 7 days. Only 4 newborns were treated, one by corticosteroid and 3 by immunoglobulins, with a good progression and only one of the untreated is always followed for thrombocytopenia.
Summary/Conclusions: The de novo ITP appearing during pregnancy is an etiological eventuality to be evoked in front of a thrombocytopenia of the pregnant woman after elimination of the other causes related to the pregnancy and in front of the non-resolution after the delivery. The pre-existing ITP does not necessarily.

Quality of life, palliative care, ethics and health economics

PB2126

QUALITY OF LIFE AND SYMPTOM BURDEN IN PATIENTS WITH MULTIPLE MYELOMA

B. Sidi Mohamed El Amine[1,*], H. Asma[1], O. Fouzia[1], S.A. Najet[1], C. Malika[1], Z. Naima[1], Z. Zahia[1]
[1]Hematology department, Universitary hospital of Sidi Bel Abbés, Sidi Bel Abbes, Algeria

Background: Multiple myeloma (MM), the second most common hematological cancer, remains incurable. Its incidence is rising due to population ageing. Despite the impact of the disease and its treatment, not much is known about health-related quality of life (QoL) of patients with MM.
Aims: This study aimed to (1) Determine symptom prevalence in patients with MM on disease-modifying treatment, and identify the range and nature of these symptoms within the dimensions of physical, psychological, social well-being. (2) Measure the QoL of patients. (3) Compare the above-mentioned parameters to the general population.
Methods: Adults with multiple myeloma attending the hematology day unit in hematology department from November 2016 to January 2017 were eligible for inclusion in a cross-sectional. Consenting patients completed 2 validated questionnaires, the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) supplemented by the myeloma-specific module (EORTC QLQ-MY20).
Results: Forty-seven patients were included for analysis: 51, 1% were male and 48,9% were female. Mean age was 64,7 years (range 42-82, standard deviation 11.50). The QoL scores were significantly lower than the general population (54,7 *vs* 71,2). The most commonly reported physical symptoms were pain (72%), fatigue (70%) and insomnia (66%). About 61% of the patients were burdened by financial worries. On multivariate analysis, a good performans status (PS≤1) and a response of the disease to therapy (at least a partial response) were associated with high scores of QoL (P=0,01, P=0,03 respectively).
Summary/Conclusions: Patients with MM have a lower QoL than the general population and are symptomatic across physical, psychological and financial domains. They represent a polysymptomatic patient cohort with a complexity of need that merits a holistic multidisciplinary approach, and consideration of specialist symptomatic or palliative care review.

PB2127

QUALITY OF LIFE IN ANEMIC PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

N. Romanenko[1,*], S. Bessmeltsev[1], A. Romanenko[2], N. Potikhonova[1], M. Zenina[1]
[1]Clinical Hematology, Russian Research Institute of Hematology and Transfusiology, [2]Neurology, Children Hospital of St. Olga, Sankt-Peterburg, Russian Federation

Background: Anemia is a common complication of patients with hematological malignancies (HM), which may progress undergoing antitumor treatment significantly decreasing hemoglobin concentration and occur symptoms as fatigue, dizziness, palpitations, dyspnea markedly reduce patient activity, resulting in impaired Quality of Life (QoL).
Aims: To compare of QoL in HM's patients with different grades of anemia.
Methods: In this study were included following patients (n=326) in the age of 19-82 (Me=65) years: myelodysplastic syndrome (n=37), acute myeloid leukemia (n=20), acute lymphoid leukemia (n=7), primary myelofibrosis (n=23), chronic myeloid leukemia in blast crisis (n=6), multiple myeloma in II and III st. (n=126), Non-Hodgkin's lymphoma in III-IV st. (n=40) and chronic lymphocytic leukemia in B or C st. (n=67). Patients were examined: 1) clinical blood test (hemoglobin concentration) to assess anemia's grade; 2) the Functional Assessment of Cancer Therapy-Anemia (FACT-An) scale to measure of QoL. The FACT-An questionnaire consists of a general questionnaire (FACT-G), measuring domains of physical well-being (PW), social/family well-being (S/FW), emotional well-being (EW), functional well-being (FW), an anemia-specific questionnaire – Anemia subscale (AnS), measuring fatigue-associated items – Fatigue subscale (FS) and non-fatigue-associated items – Non-Fatigue subscale (NFS). Patients were divided into six groups according to the Hb concentration: 1) the first group – Hb was 4.0-6.4 g/dl (Me=5.7 g/dl); 2) the second – Hb 6.5-7.9 g/dl (Me=7.2 g/dl); the third – Hb 8.0-9.4 g/dl (Me=8.6 g/dl); the forth – Hb 9.5-10.9 g/dl (Me=10.8 g/dl); the fifth – Hb 11.0-11.9 g/dl (Me=11.4 g/dl); the sixth – Hb 12.0-14.4 g/dl (Me=13.0 g/dl). The sixth group was control.
Results: In the first group of patients (n=34) with severe anemia grade 4 QoL was revealed too poor; number of points in the subscale of PW was 14.0±0.9, in S/FW – 14.2±0.7; EW – 10.3±0.9, FW – 18.5±0.8, AnS – 41.2±1.6, FS – 27.8±1.3, NFS – 13.4±0.6. In the second group of patients (n=53) with anemia grade 3 QoL was poor too; in PW was 13.3±0.8, in S/FW – 14.4±0.6, EW – 9.9±0.7, FW – 18.2±0.6, AnS – 38.5±2.3, FS – 26.8±1.7, NFS – 12.0±0.7. In the third group of patients (n=72) with anemia grade 2 QoL in the subscale of PW was 11.5±0.7, in S/FW – 14.0±0.5, EW – 8.6±0.6, FW – 16.9±0.5, AnS – 36.1±1.9, FS – 25.5±1.4, NFS – 11.6±0.6. In the forth group of patients (n=70) with anemia grade 1 QoL in PW was 11.3±0.7, in S/FW – 14.3±0.6, EW – 8.4±0.8, FW – 16.9±0.7, AnS – 34.7±1.6, FS – 23.0±1.2, NFS – 11.7±0.6. In the fifth group of patients (n=41) with anemia grade 0 QoL in PW was 11.1±0.9, in S/FW – 14.9±0.8, EW – 7.6±0.6, FW – 16.4±0.5, AnS – 34.6±2.2, FS – 23.7±1.6, NFS – 10.9±0.7. In the sixth group of patients (n=56) without anemia QoL in the subscale of PW was 7.5±0.7, in S/FW – 13.6±0.6, EW – 6.4±0.5, FW – 14.8±0.7, AnS – 23.4±1.5, FS – 14.9±1.0, NFS – 8.4±0.6.
Summary/Conclusions: QoL was found too poor in patients with Hb <8.0 g/dl. QoL wasn't satisfactory in patients with Hb 8.0-11.0 g/dl. But the QoL improvement were greater in patients with Hb levels >11.0-12.0 g/dl (p<0.05). These data suggest that early correct anemia with red blood sells transfusions and erythropoiesis-stimulating agents can improve QoL in a clinically meaningful way.

PB2128

AN ANLYSIS OF THE IMPACT OF LOCAL COSTS OF MEDICINES ON COST EFFECTIVENESS OF THE TREATMENT OF CANCER ASSOCIATED THROMBOSIS.

E. Reimer[1,*], D.M.R. Lipp[2], M. Gotfredsen[1], M. Feuerbach[3]
[1]Thrombosis, LEO Pharma, Ballerup, Denmark, [2]Haematology and Oncology, [3]Health Economy, German Oncology, Hamburg, Germany

Background: New research has surfaced in relation to health care resource utilization and costs in Cancer Associated Thrombosis (CAT). The studies originate from the US and are difficult to transfer directly to other countries. A few studies in Europe focusing on the total cost of CAT seem to indicate that the cost data in the field of CAT varies greatly between regions. To examine the importance of region specific cost elements in relation to research related to CAT, we studied the cost driver in the newest and most relevant health economic research and compared it with the costs from 6 European countries as well as Canada.
Aims: To highlight the importance of localized or regionalized cost inputs as cost drivers when considering cost effectiveness in relation to CAT.
Methods: The cost driver is the medication in a recent analysis by Connell 2016 and thus the focus of our analysis. The American paper incorporates outcomes from 6 RCTs for treatment with LMWH in patients with CAT. The annual medication costs of LMWH for daily treatment in 365 days were 32,120 USD in wholesaler acquisition cost (WAC). For VKA the annual medication cost for 365 days was 44 USD. LMWH is the cost driver but is not cost effective due to the cost of it. The study finds that " *The one-way sensitivity analysis shows that LMWH would become the preferred strategy once its annual cost was less than $7177*" . In the present analysis, the daily cost acquisition cost Wholesaler Purchasing Price (WPP) (which corresponds to the American WAC) for a LMWH (prefilled treatment syringes with Tinzaparin) was gathered in 7 large markets using a data retrieval from IHS global insights systems (Jan 2016). In addition to this, the role of the cost driver was also compared to other publications.
Results: Simply by applying the local unit cost for the treatment with LMWH for these countries, the conclusion becomes notably different. LMWH becomes the cost effective alternative in the European countries as well as in Canada with annual costs below 7177 USD. The price for VKA is comparable to that in the US, and does not change the cost effectiveness ratio.
The data from the retrospective cost of CAT study that the cost of the hospitalization of was 19% of the total cost of CAT and the CAT medication 11% of the total cost of CAT. This outlines hospitalization is a cost driver as well and not only the medication. Similar conclusions were reached in other studies. In summary, the role of the cost driver can change as a consequence of the localization of the costs. This outlines the great variation in costs in terms of CAT, and the caution it must be used with (Table 1).

Table 1.

Average Wholesaler Purchasing Price (WPP) in USD for Tinzaparin prefilled treatment syringes	Annual WPP cost (365 days of treatment)	Tinzaparin below threshold for Cost Effectiveness outlined by Connell, 2016; 7177 USD pr year
UK	USD 2.847	*Yes*
Germany	USD 3.358	*Yes*
Spain	USD 3.176	*Yes*
France	USD 3.869	*Yes*
Sweden	USD 2.811	*Yes*
Greece	USD 2.993	*Yes*
Canada	USD 6.879	*Yes*

Summary/Conclusions: The exercise shows that using local input changes the conclusion and could potentially influence local evaluations related to the access for LMWH treatment for CAT. Tinzaparin was found to be a cost effective LMWH over VKA in 6 European Countries as well as in Canada, when local medication costs were used. This was in contrast to the conclusion in the US. Not using localized or regionalized cost inputs could potentially lead misinterpretations about cost effectiveness of CAT treatments.

PB2129

MINIMIZING THE RISK OF MUCOSITIS IN HEMATOLOGIC PATIENTS WITH TOPICAL PRODUCTS

I. Ursuleac[1,*], Z. Varady[1], A. Enache[2], A. A. Tomescu[2], R. Dragan[2], D. Coriu[1]
[1]Hematology, [2]Fundeni Clinical Institute, Bucharest, Romania

Background: Mucositis is a frequent severe complication associated to aggressive therapies of hematological malignancies with chemo and/or radiation (therapy), conditioning therapy in stem cell transplants. Regularly occurs at 3 to 10 days after chemotherapy and about 6 to 8 weeks after radiotherapy. It is self-limited within 2-4 weeks, but in this period the patient is vulnerable to systemic infections (bacterial and fungal). It could also compromise the optimal timing and dosage of the chemotherapy schedule, induce psychosocial distress, prolonged hospitalization and finally, higher costs.
Aims: Evaluating the efficacy of Gel X® in chemotherapy induced mucositis. GelX® is a topical product that contains Zinc gluconate+taurine, with bacteriostatic and anti-inflammatory effect, easy to use for the patient, in order to prevent and reduce pain and severity of oral ulcers, making a barrier for mucosae
Methods: A retrospective analysis of 77 adult patients: 17 with hematological treatments and 60 with allogeneic stem cell transplantation. 17 were diagnosed and treated between January 2015 and December 2016 with various hematologic malignances (5 AML, 2 ALL – 1 Ph positive, 2 blastic phases of CML, 3 AILT (CHOP/DA-EPOCH), 2 DLBCL (RCHOP), 1 FL (RCVP), 1 MM (radiotherapy), 1Hodgkin disease (ABVD). Treatment regimens used for acute leukemias/blastic phases of CML were: "3+7" (3 cases), MEC (1 case), high doses ARA-C (1), GMALL protocol (1), HyperCVAD (1), Idarubicine and ARA-C(1) HD-MTX(1) . GelX® was indicated as prophylactic treatment for eight patients, because the risk of mucositis was high (aggressive chemotherapy, bad oral condition, risk of prolonged neutropenia). Curative treatment of grade 3-4 mucositis was indicated for 10 patients (one was initially treated with curative intention and after that with prophylaxis). In 60 patients allografted for various hematological conditions (35 unrelated, 4 haplo and 21 sibling) GelX® was prescribed for treating grade 3-4 mucositis. For the 35 cases with unrelated allotransplant (21 AML, 4 ALL, 2 SA, 2ATLL, 2 MMM, 2 CML, 1 MDS, 1 BH), 16 cases of grade 3-4 mucositis has appeared .The conditioning regimen was mieloablative(14 cases) and reduced intensity(21 cases) .There were 21 cases of sibling allotransplants (6AML, 3 ALL, 1 ATLL, 5 LMNH, 1CLL, 2 SAA, 2 CML, 1 mycosis)with 10 cases of mucositis grade 3-4. The regimens used were 6 mieloablative and 15 nonmieloablative. 3 from 4 cases of haplotransplant with nonmieloablative conditioning (2MDS, 1 AML and 1 SAA) had grade 3 mucositis.
Results: Prophylactic treatment induced a reduction in the grading of mucositis (grad 1-2) and a shorter period of evolution (5 days) *versus* grade 3-4 mucositis and prolonged duration of oral lesions for those with curative treatment. From 60 patients allotransplanted, 30 patients experienced grade 3 and 4 mucositis with a medium duration of five days. All of them received GelX® as prophylactic treatment.
Summary/Conclusions: Prophylaxis is the key of successful evolution in mucositis (time to heal shorter than 10 days). Identifying candidates for mucositis is mandatory and the product should be applied starting with the chemotherapy (or in the first 24 hours on the onset of chemotherapy) in order to minimize the risk of mucositis appearance.

PB2130

EUROBLOODNET: THE EUROPEAN REFERENCE NETWORK IN RARE HEMATOLOGICAL DISEASES

M.D.M. Mañu Pereira[1,*], V. Gutierrez Valle[1], J.L. Vives Corrons[1], B. Gulbis[2], P. Fenaux[3]
[1]Red Blood Cell Pathology and hematopoietic defects Unit, Josep Carreras Leukaemia Research Institute, Barcelona, Spain, [2]Laboratoire Hospitalier Universitaire de Bruxelles - ULB, Brussels, Belgium, [3]Service d'Hématologie Séniors, Hôpital Saint-Louis - Université Paris, Paris, France

Background: Almost all hematological disorders are rare diseases, affecting less than 1 in 2000 individuals, justifying their inclusion in a European Reference Network (ERN). ERN are networks created following the Directive 2011/24/EU on cross border health which include nationally recognized Centres of Expertise aiming to ensure the same level of access to health services of European citizens affected by a rare disease. EuroBloodNet, the ERN in Rare Hematological Diseases (RHD), results from a joint effort of the European Network on Rare and Congenital Anaemias (ENERCA), the European Hematology Association (EHA), and European hematology patient organisations represented in both the EURORDIS European Patient Advocacy Groups (ePAGS) and the EHA Patient Organisations Workgroup. EuroBloodNet gathers 66 highly skilled and multidisciplinary healthcare teams in 15 Member States, and advanced specialized medical equipment and infrastructures which will facilitate concentration of resources for the design, validation and implementation of high-quality and cost-effective services aimed at facing the challenges of RHD.
Aims: EuroBloodNet's main goal is to improve the healthcare and overall quality of life of patients with a RHD by 1) Improving equal access to highly specialized healthcare delivery for RHD across Europe 2) Promoting best practices in prevention, diagnosis and safe clinical care across Europe 3) Disseminating cutting-edge knowledge and facilitating continuous medical education in the field of RHD 4) Providing inter-professional consultation by sharing of expertise and safe exchange of clinical information 5) Fostering European cooperation in highly specialized procedures for diagnosis, promotion of clinical trials and innovative treatments and research.
Methods: RHD are covered in two main thematic groups: non-malignant diseases and malignant diseases, and six sub-thematic areas. Non-malignant diseases include 4 sub-thematic areas: 1) Rare red blood cell defects 2) Bone marrow failure (BMF) and hematopoietic disorders 3) Rare Bleeding-Coagulation disorders and related diseases and 4) Haemochromatosis and hereditary iron metabolism disorders. Malignant diseases include 2 sub-thematic areas: 1) Myeloid malignancies and 2) Lymphoid malignancies. Methods and tasks aiming to achieve EuroBloodNet specific objectives have been split into five categories of Transversal Field of action (TFA): 1) Cross border health 2) Best practices 3) Continuing medical education 4) Telemedicine 5)Clinical trials and research.
Results: Expected outcomes include reduction of healthcare inequalities for RHD in the EU by a) establishing a cross-border referral system allowing safe information, samples and patient mobility, b) provision of equal access to highly specialised procedures and innovative therapies resulting from best practice sharing, continuous medical education and virtual inter professional consultation for complex RHD cases, and c) facilitation of a timely and efficient translation of research results into patient oriented strategy at the clinical and the public health level.
Summary/Conclusions: EuroBloodNet, with the experience gained thanks to the EU-funded ENERCA and EHA, will seek to improve access to healthcare for RHD patients, to promote guidelines and best practice, to improve training and knowledge sharing, to offer clinical advice where national expertise is scarce, and to increase the number of clinical trials in the field.

PB2131

2016 REVISION OF WHO CLASSIFICATION OF TUMOURS OF HAEMATOPOETIC AND LYMPHOID TISSUES: IMPACT ON INVESTIGATING PATIENTS WITH ISCHAEMIC STROKE

C. Philip[1,*], J.D. Pandian[2], M.J. John[1], P.N. Sylaja[3], A. Mathew[1], S. Kaul[4], D. Khurana[5], M. Padma[6], D. Arora[2], A. B. Singhal[7]
[1]Clinical Haematology, [2]Neurology, Christian Medical College & Hospital, Ludhiana, [3]Neurology, Sree Chitra Tirunal Institute of Medical Sciences and Technology, Thiruvananthapuram, [4]Neurology, Nizam's Institute of Medical Sciences, Hyderabad, [5]Neurology, Postgraduate Institute of Medical Education and Research, Chandigarh, [6]Neurology, All India Institute of Medical Sciences, New Delhi, India, [7]Neurology, Massachusetts General Hospital, Boston, United States

Background: Under diagnosis related to the earlier hemoglobin (Hb) or hematocrit (Hct) diagnostic criterion is one reason to the 2016 revision of the diagnosis of PV in the World Health Organization (WHO) classification of Tumours of Haematopoetic and Lymphoid tissues. Bone Marrow Biopsy (BM) and molecular markers (JAK2) are recommended to establish the diagnosis in those with the lower threshold(Arber DA et al,2016). This potentially could result in increased numbers and costs of investigations. The lower thresholds are aimed to identify those previously referred to as masked PV (mPV) who have been recognized to have an increased incidence of thrombosis (Barbui T et al, 2014 & 2015).We hypothesized that the revision would increase the incidence of patients with Ischaemic stroke and potential PV who would then require additional investigations.
Aims: To determine number of patients with young strokes with potential PV on application of the 2016 revised WHO criteria for PV.
Methods: We undertook an analysis of records of patients with ischemic stroke prospectively maintained in the The Indo-US Stroke Registry and Infrastructure Development Project. This registry enrolled adult patients admitted with imaging-confirmed ischemic stroke <2 weeks after symptom onset. The Indo-US Stroke Registry and Infrastructure Development Project, includes 5 geographically diverse centers in India and one in USA. The registry data was entered into a central web-based electronic database. From January, 2012 to March, 2014, 2076 patients with new onset ischemic stroke were evaluable in the Indian arm of the Indo-US Stroke registry. We compared the incidence of polycythemia as per the 2016 revision against the earlier (2008) Hb diagnostic criterion.
Results: There were 24 (1.2%) patients with potential PV which was revised to 107 (5.2%) on applying the 2016 Hb criterion. The exact McNemar's test determined that there was a statistically significant difference in the proportion of polycythemics, p=.000. Considering the potential of comorbidities in the elderly to confound the association of polycythemia with Ischaemic stroke, we

separately analyzed only those with young stroke (Age <45). In this cohort there were 420 patients. A total of 6 (1.4%) patients had potential PV based on the 2008 Hb criteria. On applying the 2016 revision; 37 (8.8%) patients fulfilled the Hb criteria. An exact McNemar's test determined that there was a statistically significant difference in the proportion of polycythemics, p=.000. Separate analyses by gender was not significant in females, P=0.5; but significant in males, p=.000. There were an additional 29 males with the revised criteria for polycythemia. The impact of cost in influencing treatment decision from resource limited countries with predominant out of pocket health expenditure has been earlier reported (Philip C et al, 2015). This revision promotes the routine use of BM and JAK-2. In our analysis we estimate this new criterion would add to the costs to each patient (7000 per our centre estimate).
Summary/Conclusions: The present data shows that there exists a significant difference in the incidence of polycythemia in thrombosis (Ischaemic Stroke) on applying the revised criteria. The requirement to additionally investigate them with BM and molecular markers for PV has potential economic implications.

PB2132

PATHOPHYSIOLOGICAL MECHANISMS INVOLVED IN THE DEVELOPMENT OF ANEMIA IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA

M.-A. Gaman[1,*], A. Papoi[2], A. M. Gaman[3,4]
[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, [2]University of Medicine and Pharmacy of Craiova, [3]Hematology, Filantropia City Hospital, [4]Pathophysiology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background: Non-Hodkin's lymphomas (NHL) are a group of heterogenous malignant lymphoid disorders that associate anemia either from diagnosis or during the evolution of the disease. The anemic syndrome can be present at the moment of diagnosis or can develop during the evolution of non-Hodgkin's lymphomas, with negative effects on the therapeutic regimen due to reduction of intensity and density of drug doses, overall survival and quality of life of these patients. Various pathophysiological mechanisms responsible for the development of anemia are depicted in literature: pro-inflammatory cytokines and hepcidin action on iron metabolism and erythropoiesis, bone marrow failure caused by infiltration of malignant lymphomatous cells, cytopenias secondary to chemotherapy, immune peripheral destruction of red blood cells, iron and folate deficiency due to chronic bleeding.
Aims: To evaluate the prevalence of anemic syndrome in patients with non-Hodgkin's lymphomas and the pathophysiological mechanisms involved in the development of anemia.
Methods: A retrospective study was conducted on 85 patients (informed consent obtained) with non-Hodgkin's lymphoma, who were admitted to the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, in between 2013 and 2015, in order to evaluate the prevalence and pathophysiological mechanisms involved in the development of anemia in this study group.
Results: In our study group, the median age at diagnosis of non-Hodgkin's lymphoma was 64 years, sex distribution was males:females=1,3, and the rural to urban area index=1,2. 85,88% of patients had B type NHL and 14,12% T type NHL. 20% of NHL were indolent lymphomas, aggressive lymphomas in 54% cases and very aggressive lymphomas in 26%. NHL repartition on stage of disease revealed: type I – 2.35%, type II – 18.81%, type III – 57.64%, and type IV – 21.16%. In our study group, 84% of patients enrolled had anemia, with the anemic syndrome affecting the 50-59 years and 70-79 years age groups. 59.73% of patients had anemia at diagnosis and 40.27% of patients developed anemia during the evolution of NHL. The pathophysiological mechanisms involved in the development of anemia were: perturbations of iron metabolism and erythropoiesis under pro-inflammatory cytokines and hepcidin actions (47.25%), bone marrow failure induced by lymphomatous infiltration (25%), anemia induced by chemotherapy (18.05%), and autoimmune hemolysis (9.7%). Five patients with anemia induced by chemotherapy and three patients with lymphomatous infiltration of the bone marrow also associated iron and/or folate deficiency.
Summary/Conclusions: In our study, anemia was present in 84% of NHL cases, more frequently found in patients that associated comorbidities and belonged to the 50-60 years and 70-80 years age groups. In half of the cases, anemia was moderately severe. 47.25% of patients had simple chronic anemia due to perturbations of the iron metabolism and of erythropoiesis, and 25% of patients presented anemia due to bone marrow failure. Chemotherapy lead to an anemic syndrome in 18.05% of cases, whereas hemolysis of autoimmune cause was responsible for 9.7% of cases of anemia diagnosed. The management of anemia is extremely important in patients with NHL because it influences the administration of chemotherapy (dose intensity and density), prognosis and quality of life.

PB2133

SAFETY OF RITUXIMAB BIOSIMILAR (NOVEX®) IN THE ROUTINE USE TREATMENT IN ARGENTINA.

G. Milone[1,*], M. I. Penna[2], F. Fernandez[2], E. Spitzer[2], S. Millan[3], S. Mariani[3], N. Español[3], R. Gomez[2]
[1]Hematología, Centro Médico Hematológico, [2]Laboratorio Elea, Buenos Aires, Argentina, [3]Mabxience, Madrid, Spain

Background: Novex® is a biosimilar by design of the reference product Mabthera®/Rituxan®. Novex® was approved in Argentina following ANMAT's Biosimilar guidelines, having the same indications as the reference product, and is commercialized by Laboratorio Elea. As part of its Risk Management Plan (RMP), Laboratorio Elea implements an active pharmacovigilance program as defined in Argentina regulation. Periodically reports ANMAT RMP status and results.
Aims: To describe frequency and pattern of adverse events during the use of NOVEX® in treatments registered along an active pharmacovigilance program in order to oversee the safety profile of NOVEX® in the real clinical practice and maintain the benefit-risk evaluation.
Methods: A treatment Registry for NOVEX® was implemented from the beginning of NOVEX® commercialization as part of the RMP. The Data Lock Point for this report is Jan 31st, 2017. Physicians prescribing NOVEX® were requested to fill a form indicating age and gender, treatment start date, treated pathology, dosing and dose frequency. Such data was recorded in a database. After a preset time, physicians were contacted by Laboratorio Elea to ask them about the treatment outcome and Adverse Event occurrences. If adverse events were detected they reported each occurrence as Individual Case Safety Report (ICSR), they were registered using the MedDRA dictionary (version 19.1) for its codification.
Results: The total number of participating physicians was 151. During this period, they reported 638 treatment initiations, 389 of which had at least 1 follow up point and were included in further analysis. 53% male. Mean age 64.1 years. Hematological indications were more than 90%. More than 90% of indications were approved indications. Nevertheless, we detected off-label use**.** Total cycles received for any approved indication had a mean number of 5.7. Total received Individual Case Safety Reports were 17, indicating a relative frequency of 4.4% of Individual Case Safety Report. Occurrence rates were 1.2 Individual Case Safety Report per 100 administered cycles, and 0.020 per 100 treatment days. Eleven Individual Case Safety Reports were classified as serious (SAE) because they had at least one manifestation that prolonged hospitalization, endangered life or was death-associated. The most frequent AE reported was acute reaction related to infusion (9 cases), followed by cardiovascular manifestations (2 arrhythmia, 1 cardiac failure and 1 ischemic stroke), infections (1 pneumonia, 1 progressive multifocal leukoencephalopathy), neurologic (1 paresthesia), cytopenias (1 pancytopenia) and cutaneous (1 bullous dermatitis).
Summary/Conclusions: The activities developed under this active pharmacovigilance program showed great value allowing us not only to monitor the adverse event pattern but also to detect off-label use as part of real life treatments. This report showed a similar safety profile to that of the reference product concluding that NOVEX®, in terms of tolerability, is similar to the reference product. Pharmacovigilance is cornerstone in the development of biologicals, especially biosimilars, as a tool to assist in the knowledge about their safety profile.

PB2134

DEPRESSION AS THE PRESENTING SYMPTOM OF CENTRAL NERVOUS SYSTEM LYMPHOMAS IN NORTHWESTERN TURKEY

E.G. Umit[1,*], D.B. Esen[1], M. Baysal[1], A.M. Demir[1]
[1]Hematology, Trakya University Faculty of Medicine, Edirne, Turkey

Background: PCNSL represents approximately 4 percent of newly diagnosed primary central nervous system (CNS) tumors, with an age-adjusted incidence rate of four cases per million persons per year. Most cases of non-AIDS related PCNSL are diagnosed in patients between 45 and 65 years of age, with a median age at diagnosis in the fifth decade. The most notable risk factor for the development of PCNSL is immunodeficiency including HIV infection, iatrogenic immune suppression, and congenital immune deficiencies. Antecedent flu-like or gastrointestinal illnesses or a history of autoimmune diseases were reported. Presenting symptoms may include focal neurologic deficits, neurophyschiatric symptoms, signs of increased intracranial pressure, seizures or ocular symptoms. Neurophyschiatric symptoms like depression, apathy, psychosis, confusion, memory impairment, slowness of thought are generally undernoticed or underestimated due to the increased rates of depression and tendancy towards antidepressant use. Diagnosis is based on imaging of the central nervous system (CNS), ideally with contrast-enhanced magnetic resonance imaging (MRI), cerebrospinal fluid (CSF) analysis, unless contraindicated due to elevated intracranial pressure The radiographic lesion tends to be a solitary non-hemorrhagic mass, situated in the deep white matter adjacent to the ventricular surface.
Aims: We aimed to evaluate the presence of depression and antidepressant use before the diagnosis of CNS lymphoma and emphasize the duration between the diagnosis of depression and lymphoma.
Methods: Data of 40 patients with CNS lymphoma were evaluated in a retrospective manner. From their national health records, prescription for antidepressant and anxiolytic drugs with their psychiatric diagnosis, time before the diagnosis of CNS lymphoma, the branch of the prescribing physician, presenting symptoms

from their medical files, type and treatment of lymphoma and survival were recorded. OECD international statistics as well as Turkish Statistical Institute data for national antidepressant use were collected and interpreted.
Results: Of the 40 patients, 14 were male (35%) while 26 were male(65%). Mean age was 60,5 years (38-78). 7 patients were alive (17.5%). Method for diagnosis was radiological imaging (magnetic resonance imaging) in 27 patients (67.5%) while in 13 patients, diagnosis was supported with histopathological confirmation (32,5%). Mean survival was 8,6 months (2-24 months). As the complaint for medical help seeking, 4 patients presented with neurophyschiatric symptoms while 16 patients presented with headache (40%) and 20 patients (50%) presented with neurological defects. On the other hand, prior to lymphoma diagnosis, 7 patients were diagnosed as anxiety disorder and 13 as depression (total, 19 patients, 47,5%) and were prescribed antidepressant and anxiolytic medications. The mean duration between prescription of antidepressants and diagnosis of lymphoma was 2,6 months (0-10 months). Within the patients who were on antidepressants, 6 were female and 14 were male.
Summary/Conclusions: OECD Health at a Glance data revealed that in 2013, the defined dose per 1000 per day is 35, range of Europe is 21-88. According to our data of Ministry of Health, use of antidepressants in the general population is 10,52%, mostly in women. Within these patients, 42,37% were anxiety disorders and 22,99% were depression. In the last five years' statistics, 30% of our population was prescribed for an antidepressant. The major group of physicians presciribing these medications was family and general physicians (>45%). The most striking finding of our study was the majority of male patients receiving antidepressants before the diagnosis of CNS lymphoma with a mean delay of diagnosis as 2,6 months (0-10 months). Depression and anxiety disorders are the leading diseases of disability and the importance of organic and underlying conditions should not be underestimated relying on the increasing need of antidepressants.

PB2135

IMPACT OF U.S. FDA APPROVAL OF LENALIDOMIDE MAINTENANCE THERAPY IN THE FIRST-LINE TREATMENT OF MULTIPLE MYELOMA AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANT ON TOTAL HEALTHCARE COSTS

K. Parikh[1], J. Xie[2], C. Chen[3], C. Yang[4], A. Farrukh[5], P. Cockrum[1], A.B. Agarwal[1], S. Abouzaid[1,*]
[1]Celgene Corporation, Summit, NJ, [2]Analysis Group, Inc, Los Angeles, CA, [3]Analysis Group, Inc, Boston, [4]Analysis Group, Inc, Boston, MA, [5]Analysis Group, Inc., Los Angeles, CA, United States

Background: Lenalidomide maintenance therapy after autologous hematopoietic stem cell transplant (auto-HSCT) in the first-line treatment has been shown to improve progression-free survival (PFS) and overall survival (OS) in multiple myeloma (MM) patients.
Aims: This study assessed the budget impact of the United States (U.S.) Food and Drug Administration (FDA) approval of lenalidomide maintenance therapy on total healthcare costs of a U.S. health plan.
Methods: An economic model was developed to estimate the incremental (additional) total plan costs (in 2016 USD) of maintenance therapy in each year for the first 3 years after lenalidomide monotherapy (R) maintenance therapy approval. The number of post auto-HSCT adult MM pts eligible for initiating maintenance therapy was estimated from published epidemiological data and an analysis of Connect® MM Registry data. Clinical endpoints for R-maintenance, including time on treatment, PFS and OS, were obtained from a meta-analysis of published clinical trials (CALGB, IFM, and GIMEMA). The use of common off-label maintenance therapies was considered. Types of costs included in the model were drug, drug administration, adverse events (AE), AE monitoring, one-time progression and terminal care costs.
Results: In a hypothetical U.S. health plan with 1 million members, the number of adult MM pts eligible to initiate post-ASCT maintenance therapy was estimated to be 28. Among them, 14.8 pts initiated R-maintenance in Year 1, 15.2 in Year 2, and 15.3 in Year 3, representing an incremental increase of 2.9%, 4.2% and 4.4% after R-maintenance therapy approval, respectively. After considering additional costs of maintenance, as well as potential offsets resulting from delayed progression the incremental total healthcare costs by year are listed in the Table 1. Results were consistent across all total plan, per patient per year, and per member per month costs. Deterministic sensitivity analysis showed that the model results were robust to the variations of key model inputs.

Table 1.

	Healthcare Costs		
	Year 1	Year 2	Year 3
Incremental Plan total	$67,617	$176,262	$271,929
Incremental Per patient per year	$2,405	$3,222	$3,402
Incremental Per member per month	$0.0056	$0.0147	$0.0227

Summary/Conclusions: Approval of lenalidomide monotherapy for maintenance after auto-HSCT in the first-line treatment of MM has minimal impact on total plan costs, primarily due to the small incident population and the already common use of lenalidomide in post auto-HSCT maintenance.

PB2136

LAPAROSCOPIC APPROACH CAN EXTEND THE INDICATIONS OF SPLENECTOMY: ANALYSIS OF 31 CONSECUTIVE PATIENTS WITH MALIGNANT HEMOPATHIES

A. Salaroli[1,*], B. Cadiere [2], C. Spilleboudt[1], M. Vercruyssen[1], A. de Wind[3], M. Maerevoet[1], G. Dapri[2], G. B. Cadiere[2], D. Bron[1]
[1]Department of Hematology, Institut Jules Bordet, ULB, [2]Department of Digestive Surgery, Hôpital St Pierre, [3]Department of Pathology, Institut Jules Bordet, ULB, Brussels, Belgium

Background: Surgical resection of large spleens may eliminate a significant amount of tumor, allow definite diagnosis of malignant disorder, ameliorate abdominal symptoms and resolve cytopenia. However, because of short term perioperative events (25%) and long term immunosuppression (increased risk of infections caused by encapsulated bacteria) physicians can be reluctant to choose splenectomy, especially in older patients or patients with comorbidities. The role of laparoscopic splenectomy (LS) in patients with hematological malignancies is still unclear. Nevertheless, the ageing of the world's population and the increased incidence of Non-Hodgkin's Lymphoma are increasing the indications for splenectomy, requiring a well-tolerated and less invasive procedure.
Aims: The aim of this review is to analyze our single-center experience of LS performed for malignant Hemopathies. Results are compared with LS for benign splenomegaly and the risk of locoregional dissemination or inadequacy of fragmented histological sample were analyzed.
Methods: We retrospectively analyzed 50 patients who underwent LS between 2005 and 2016 at Saint-Pierre Hospital. Anterior approach was used in 12 patients whereas in the remaining 38 cases, a semi-lateral position was chosen. All the patients received the triple vaccination (Streptococcus pneumoniae, type B Haemophilus influenzae, and Neisseria meningitidis). Patients characteristics, safety data such as early (<30 days) and late (>30 days) morbidities and mortality and efficacy (hematological recovery, accuracy of histological diagnosis) were analyzed.
Results: 19 patients underwent splenectomy for benign hemopathies (SBH) and 31 patients for malignant hemopathies (SMH). Non-Hodgkin's lymphomas (12) and idiopathic myelofibrosis (10) were the most common causes of splenectomy followed by chronic lymphocytic leukemia (7), hairy cell leukemia (1) and hodgkin's lymphoma (1). Patients' age (67 +/- 12 years, ranging from 36 to 87 in SHM, and from 11 to 71 in SBH), prior abdominal surgery (18/31) and spleen volume (1515 +/- 662 mL, ranging from 220 to 3000ml in SMH, and from 90 to 1500ml in SBH) were significantly higher in the SMH group (p <0.05). There was no significant difference in surgical time (150 *vs* 146 min, p=0.8), blood losses (243 *vs* 402 mL, p=0.26) and duration of hospitalization (5.4 *vs* 7.5 days, p=0.19) between SMH and SBH. No case of locoregional dissemination was experienced. The early morbidity of the SBH group was 10% and 13% for the SMH group (p=1). Late morbidity was 0% in the SBH group and 13% in the SMH group (p=0.28). This could be explained by a combination of underlying disease and immunosuppression (2 sepsis and 2 deep vein thrombosis). There was one conversion to open surgery and perioperative mortality in each group (p=1). There was no significant difference in efficacy of splenectomy, with respectively 83% and 79% (p=0.91) or quality of histological sample for pathological report between SBH and SMH. In the SMH group, 4 out of 31 patients received a pre-surgical corticosteroid treatment, with a pre-surgical platelets level of 156 +/- 108 x 10^3/mL, white blood cell level of 15696 +/- 18950/mL and Hemoglobin level of 10.1 +/- 1.6 g/dL. Regarding the efficacy of LS in correcting hypersplenism in the SMH, a significant difference in term of platelets recovery after 1 month from the surgery was shown in patients efficiently *Vs* inefficiently operated (respectively 387 +/- 125 *Vs* 138+/- 90 x 10^3/ml, p <0,05). The median follow up is 39 +/- 37 months and 80% achieved a hematological recovery.
Summary/Conclusions: LS is a safe and less-invasive procedure in patients affected by Malignant Hemopathies. This approach is also well tolerated in older patients (median 67yrs) and in patients with large spleen (1515+/-660 ml), extending the indication for laparoscopic SHM even in older patient and in patients with high volume spleen. Compared to historical data, LSy for Malignant Hemopathies shows better early and late morbidities. Our data shows however a trend for higher late morbidity in the SMH group, warranting a careful long term follow-up in this subset of patients.

PB2137

ARE WE AWARE OF ANXIETY AND DEPRESSION IN PATIENTS WITH NEWLY DIAGNOSED ACUTE LEUKEMIA?

M.H. Dogu[1,*], R. Eren[1], N. Nizam[2], O. Yokus[1], E. Suyani[1]
[1]Hematology, [2]Internal Medicine, Istanbul Education Research Hospital, Istanbul, Turkey

Background: Acute leukemia poses a high risk of stress for the patient during the process of diagnosis. The process after the diagnosis is challenging for the

patient due to urgent admission, long duration of stay in hospital, chemotherapeutic agents used in the treatment and the disease itself. Evaluating this group of patients for anxiety and depression, providing necessary professional support and revising medical treatment is therefore substantial.
Aims: In our study, we aimed to assess the risks of anxiety and depression in newly diagnosed acute leukemia patients who were admitted to hematology clinic to receive chemotherapy and provide necessary professional support along with treatment revisions and follow-up according to our findings.
Methods: Our study was performed with newly diagnosed acute leukemia patients, who were admitted to our hospital hematology clinic in a six-month period to receive chemotherapy. Demographic characteristics were noted and Hospital Anxiety and Depression Scale (HADs) was used to assess depression. Hospital Anxiety and Depression Scale (HADs) is an assessment scale developed by Zigmond and Snaith to determine the risks and assess the severity of anxiety and depression (8). The validation and reliability studies of the scale in Turkey were carried out by Aydemir et al (9). The questionnaire has a total of 14 items; seven of which measure anxiety (odd numbers) and the remaining seven (even numbers) measure depression. Each item is scored from 0 to 3. The scoring order of each item in the questionnaire is different. Items numbered 1, 3, 5, 6, 8, 10, 11 and 13 indicate decreasing severity and are scored as 3-2-1-0. On the other hand; items numbered 2, 4, 7, 9, 12 and 14 indicate increasing severity and are scored as 0-1-2-3. The cut-off value for the total score of the odd-numbered questions assessing anxiety is 10; while it is 7 for the even-numbered questions assessing depression.
Results: 21 patients were included in the study. 13 of these patients (61.9%) were diagnosed with acute myeloid leukemia (AML) and 8 (38.1%) were diagnosed with acute lymphoblastic leukemia (ALL). Median age of the patients was 45 (range: 21-69). 11 patients (52.4%) were female and 10 (47.6%) were male. 5 patients (23.8%) had comorbidities while 16 (76.2%) had none.
Anxiety evaluation revealed that 38.1% of all patients in the study experienced anxiety. The rate of anxiety was 38.5% in AML patients and similarly 37.5% in ALL patients. 45.5% of the female patients had anxiety while the rate was only 30% in male patients. The difference was not statistically significant ($p > 0.05$).
Depression evaluation revealed that 81% of all patients in the study. The rate of depression was 84.6% in AML patients and 75% in ALL patients. 81.8% of the female patients had depression while it was 80% in male patients. Neither anxiety nor depression had a significant correlation with comorbidities or gender ($p > 0.05$). Correlation analysis revealed a positive correlation between anxiety and depression ($r=0.846$; $p < 0.01$).
Summary/Conclusions: In conclusion, assessing anxiety and depression in patients with acute leukemia at the time of hospital admission is substantial for the course of and adherence to treatment. In our study, depression was distinctively more common than anxiety and there was a positive correlation between depression and anxiety. We think that including a professional for psychological support in the medical team is important for the treatment of these patients.

PB2138

GENDER DIFFERENCE IN ANXIETY FOR THE FIRST BLOOD TRANSFUION

Y. Lu[1,*], X. Zhang[1], X. Li[2], Y. Zou[1], Z. Lin[1]
[1]the third Affiliated Hospital of Sun Yat-Sen University, [2]The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Blood transfusion has several risks including allergic reaction, acute hemolysis, infectious disease and so on. Both physicians and patients are always cautious to decide on blood transfusion.
Aims: The purpose of this study was to explore whether there are gender difference in anxiety for the first blood transfusion in patients with different diseases.
Methods: 315 patients (153 men and 162 women) were enrolled in this prospective, comparative study and median age was 38 years(range 17-72). The disease consisted of 85 chronic hepatitis B, 73 leukemia, 69 gastric ulcer, 48 chronic renal failure and 40 gynecological oncology. Various blood products including plasma, red blood cells suspension and platelet were infused. Anxiety was evaluated according to the HAMA self-rating anxiety scale (SAS) during the first blood transfusion. Patients got 50 points below were divided into no anxiety group, 50 to 59 points were divided into mild anxiety group, 60-69 points were divided into moderate anxiety group and 70 points or more were divided into severe anxiety group.
Results: For patients with the same disease, more female patients were divided into moderate to severe anxiety group than male ones. The number of patients with mild anxiety was similar in female and male, and no one was divided into no anxiety group.
Summary/Conclusions: Women were more anxious than men during the first blood transfusion, which is independent of age, race, education level and kinds of blood product.

PB2139

A ROOM OF MY OWN

L. Gov Ari De-Vries[1,*]
[1]Hematology day center, Shaare Zedek Medical Center, Jerusalem, Israel

Background: Three years ago, a unit for autologous bone marrow transplant for hematological patients has been established in Shaare Zedek medical center. The patients meet with the doctors for the treatment plan usually following the diagnosis. From the point of view of a part of the patients, the process appears simple, short term, and promises cure. In reality, the process is long term, including aggressive chemotherapy prior to the transplant. The treatment is highly aggressive and toxic with many physical and mental side effects for the patient and his/her family. The transplant process requires hospital admission for about a month in an isolation room. No one is allowed in the room except for close relatives and the medical staff. The social worker, part of the caring staff, accompanies patients and families from the initial diagnosis through this taxing and stressful process. Most patients are young, average 45 years, in the middle of their careers, from a broad spectrum of occupations, education as well as social status, representing Israeli society.
Aims: 1. To accompany and empower patients by means of giving them tools to cope with the transplantation process which is a crisis situation in the midst of their lives. 2. To teach patients self-awareness. 3. Promote quality of life for the patients especially during the stay in the isolation room by way of creating a safe domain.
Methods: The following tools had been utilized: 1. The "Empowerment method". An advanced view of the powers and experiences of patients that constitute resources in addressing crisis. 2. Work of hope- finding unique meaning in life crisis.
Results: This work is based on therapeutic conversations that took place inside the isolation room with about 30 patients, mostly men, average age was 50, during the past three years. With the understanding that a patient goes from the public sphere to a private one -the isolation room- my entrance into the room was based on the ability and willingness of the patients to go into a treatment dialogue at that point and time. From the narratives of the patients, a few themes were extracted that were repeatedly discussed by most patients. 1. Fear of death. 2. Post-traumatic issues. 3. Fear of isolation. 4. The issue of relationships. 5. Mind and body. 6. Children. 7. Faith. 8. Closure
As cited by S.A, a 49 year old man "I'm afraid to give in and die, help me to stay alive. And if I die, I want to know that I have left no unfinished business."
Summary/Conclusions: From the therapy sessions it appears that the central issues that bother the patients belong to the private space and the coping with it. The process of treatment helps patients to go from the private sphere back to the public one.
Recommendations: It seems essential for the patients in the isolation room, undergoing autologous bone marrow transplant, to have therapy sessions with a qualified social worker as part of the holistic care. 'Having a room of his own' in the process enables an opportunity to examine the inner self esteem and strengths of the patients thereby patients learn to contribute to themselves from themselves.

Sickle cell disease

HYDROXYUREA INHIBITS MYELOID DIFFERENTIATION VIA NITRIC OXIDE SYNTHASE

T. Subotički[1,*], O. Mitrović Ajtić[1], M. Diklić[2], S. Vignjević Petrinović[1], M. Budeč[1], D. Djikić[1], J. Santibanez[2], V. Čokić[2]
[1]Laboratory of neuroendocrinology, [2]Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: Hydroxyurea and nitric oxide (NO) inhibit erythroid differentiation, while hydroxyurea is NO-releasing agent used in therapy of sickle cell diseases.
Aims: To study the mechanism of hydroxyurea inhibition of erythroid differentiation by exploring NO synthase (NOS) dependence.
Methods: The erythroid differentiation is studied by methylcellulose colony assay in mice, whereas presence and activation of endothelial NOS (eNOS) by immunocytochemistry and immunoblotting, respectively in K562 erythroleukemic cell line.
Results: In *ex vivo* experiments, mice exposed 7 days to hydroxyurea demonstrated significant decrease in the number of nucleated cells per femur, partially reversed by NOS inhibitor N-nitro L-arginine methyl ester hydrochloride (L-NAME). The same, but less prominent reduction has been observed with NO metabolites nitrite (NO2) and nitrate (NO3). Moreover, hydroxyurea demonstrated a large diminution in the number of bone marrow derived myeloid colony-forming unit -granulocyte/macrophage (CFU-GM), burst-forming-units-erythroid (BFU-E) and colony-forming unit-erythroid (CFU-E) colonies in methylcellulose cultures. L-NAME attenuated hydroxyurea reduction of myeloid and erythroid colonies, while by itself increased CFU-E and CFU-GM colonies and slightly BFU-E colonies. NO metabolites NO2 and NO3 generally inhibited myeloid and erythroid colonies, but the reduction was more prominent by NO2 compound. Moreover, the hematological parameters and weight (before and after treatment) of mice did not show any significant difference among studied groups. Hydroxyurea increased NO production and the number of eNOS positive K562 erythroleukemic cells, while phosphorylation of eNOS and activation of AKT/mTOR signaling was not blocked by phosphatidylinositol 3-kinase inhibition.
Summary/Conclusions: NO prodrug hydroxyurea demonstrated NOS dependence in inhibition of myeloid / erythroid differentiation, not influencing the hematological parameters.

PB2141

SLEEP DISORDERED BREATHING IN CHILDREN AND ADOLESCENT WITH SICKLE CELL DISEASE: IMPACT ON EXECUTIVE FUNCTION AND PROCESSING SPEED INDEX

M. Koelbel[1,*], J. Kawadler[2], H. Stotesbury[2], P. Balfour[2], F. Kirkham[1]
[1]UCL Great Ormond Street Institute of Child Health https://www.ucl.ac.uk/ich, London, United Kingdom, [2]Developmental Imaging & Biophysics, UCL Great Ormond Street Institute of Child Health https://www.ucl.ac.uk/ich, London, United Kingdom

Background: Studies in non-syndromic children have shown that sleep-disordered breathing (SDB) increases the risk of neuropsychological deficits and neuronal brain injury. Few authors have investigated the role in cognitive deficits of SDB and the associated hypoxia in children with sickle cell disease (SCD). Snoring and SDB is very common in children with SCD and may affect cognitive function in very young children. Previous data suggested that executive function was worse in older children with SCD and low mean overnight oxygen saturation.
Aims: We aim to investigate if SDB could be a potential factor contributing to developmental problems in cognition in children and adolescent with SCD.
Methods: We have followed up children and adolescents in the Sleep Asthma cohort who underwent Polysomnography at two different time points (1) 2006-2009 and (2) 2011-2014 and compared the sleep data with subsequent neuropsychological assessment.
Results: Worse performance was found for processing speed: PSI (p<0.01) and general intelligence (p<0.05) compared to control siblings. SDB, measured as apnea and hypoxia index (*i.e.* AHI >3%: Apnoeas and hypopnoeas with more than ≥3% desaturation), was found to impact executive function, as measured with the Tower test, (p<0.05) and PSI (p<0.05). Mean oxygen saturation during total sleep time was significantly associated with lower PSI (p<0.05). Additionally, participants who showed a worsening of their SDB symptoms in their second sleep study had lower cognitive scores (*i.e.*, executive function, p<0.05 and PSI, p<0.05) (Figure 1).
Summary/Conclusions: SDB symptoms seem to worsen into adolescence and therefore, might have a neurodevelopmental impact if left untreated; appropriate intervention might improve cognition and quality of life.

PB2142

LUNG FUNCTION IN CHILDREN AND ADOLESCENTS WITH SICKLE CELL ANEMIA: A COMPARISON BETWEEN UK AND ITALY

C. De Pieri[1,*], M. Arigliani[1], R. Colombatti[2], L. Sainati[2], K. Vecchiato[3], S. Ndoro[4], P. Cogo[1], B. Inusa[4]
[1]Department of Clinical and Experimental Medical Sciences, University Hospital of Udine, Udine, [2]Clinic of Pediatric Hematology-Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, [3]University of Trieste, Trieste, Italy, [4]Department of Pediatrics, Evelina Children's Hospital, London, United Kingdom

Background: Acute and chronic respiratory complications are common in sickle cell anemia (SCA). Subjects with SCA often have a progressive decline of lung function with age that could be influenced by the quality of healthcare and by environmental factors, such as the level of exposure to air pollution.
Aims: To compare lung function, evaluated cross-sectionally through spirometry, in children and adolescents attending sickle cell centers in UK and Italy.
Methods: Anthropometry and spirometry were recorded in patients with SCA (SS,Sb^0) aged 6-17 years of African ancestry followed at the Evelina Children's Hospital, London, UK, and at the University Hospitals of Padova and Udine, northeast of Italy. Subjects from the British cohort lived in an urban area while those from Italy came from urban and non-urban areas. Exclusion criteria were the presence of SCA-related morbidity within the last two weeks and the inability to perform a spirometry meeting the *European Respiratory Society* acceptability and repeatability criteria (Miller, Eur Respir J 2005;26:319–338), modified for children (Kirkby, Pediatr Pulmonol 2008;43:1233–1241). Portable spirometers (Pony FX, Cosmed-IT, Easy-on PC, NDD-CH) were used. Z-scores of anthropometric and spirometric data were derived, respectively, from CDC2000 and from the *Global Lung Initiative 2012* predictive equations for African Americans (Quanjer, Eur Respir J 2012; 40:1324–1343). Spirometry patterns were classified as normal, obstructive ($zFEV_1/FVC$<-1.64) or restrictive ($zFVC$<-1.64+$zFEV_1/FVC$ ≥ -1.64). Differences between groups were assessed by t-tests and considered statistically significant for p values <0.05.
Results: A total of 101 children and adolescents were included (n. 62 in UK; n. 39 in Italy; 42% girls; age-range: 6.2-17.9 years). We didn't find significant differences in mean spirometry indices between the SCA cohort from London and northeast Italy (Table 1). Nevertheless while an obstructive spirometry pattern was more common in the British cohort compared to the Italian one (respectively 22.5% *vs* 7.7%), the picture was the opposite for the restrictive pattern (respectively 11.2% and 20.5%) (Table 1). In the whole sample age was negatively correlated with both zFEV1 (Spearman's rho-0.20) and zFVC (Spearman'srho -0.24).

Table 1.

Index	Sickle cell UK	Sickle cell ITA	Diff between means (95% CI)
n (%male)	62 (54%)	39 (61%)	
Age (years)	11.9 (2.7)	11.3 (3.5)	0.6 (-0.6 to 1.9)
Height z-score	-0.11 (1.23)	-0.08 (1.09)	-0.03 (-0.53 to 0.47)
BMI z-score	-0.11 (1.71)	-0.55 (1.17)	0.44 (-0.03 to 0.91)
FEV1 z-score	-1.10 (1.04)	-0.80 (0.97)	-0.30 (-0.72 to 0.10)
FVC z-score	-0.71 (1.03)	-0.71 (0.83)	0.00(-0.43 to 0.39)
FEV1/FVC z-score	-0.43 (1.09)	-0.27(0.93)	-0.16 (-0.58 to 0.25)
Spirometry pattern			
Obstructive (% of total)	14 (22.5%)	3 (7.7%)	
Restrictive (% of total)	7 (11.2%)	8 (20.5%)	

Summary/Conclusions: Lung function of pediatric subjects with SCA living in London and in the northeast of Italy is overall comparable. Obstructive lung disease is more common among subjects with SCA living in London than in urban and non-urban areas in Italy. Differences in the level of exposure to ambient air pollution and in the prevalence of allergies between the rural and urban environment might have contributed to this finding and need to be further investigated.

PB2143

SICKLE CELL DISEASE: A NEW DISEASE IN MADRID

E. J. Bardón-Cancho[1,*], M. García-Morín[1], B. Ponce-Salas[1], Y. Aguilar-de la Red[1], A. Pérez-Corral[2], G. Pérez-Rus[2], E. Dulín[3], C. Beléndez[1], E. Cela[1]
[1]Section of Pediatric Hematology and Oncology, Department of Pediatrics, [2]Department of Hematology, [3]Newborn Screening Laboratory (Community of Madrid), Hospital General Universitario Gregorio Marañón - Facultad de Medicina - Universidad Complutense de Madrid, Madrid, Spain

Background: Sickle cell disease (SCD) was scarcely diagnosed 2 decades ago in Spain, and the Community of Madrid is a paradigm of the adjustments that had to be implemented to attend an increase of cases due to immigration.
Aims: The aim of our study was to find out the prevalence of SCD in the referral center for sickle newborn screening in the Community of Madrid, in addition to the demographic characteristics of these patients. The secondary objectives were to obtain the frequency of specific treatments or prophylaxis accomplished by these patients, and the reasons for loss to follow-up.

Methods: The study is observational, unicentric, descriptive and retrospective, carried out in February 2017 in a tertiary hospital in the Community of Madrid, Spain. All patients diagnosed with SCD and who had attended at least once to the hematology clinic for this reason were included. Demographic characteristics (date of birth, gender, country of birth) and clinical characteristics (genotype, therapy and update in follow up, like alive, deceased or lost patient) were collected. Written informed consent was signed by patients or legal guardians in accordance with the Declaration of Helsinki. The study was approved by the hospital Ethical Committee. Statistical analyses were performed using SPSS version 18.0. Quantitative variables were reported as median or mean value and range, while categorical variables were expressed as absolute value and percentage.
Results: The total number of SCD patients included was 209. Ratio boy/girl is 1.3. Most of patients were born in Spain (85%), although 8% and 5.26% were born in Africa or America respectively. Seventy three percent of the progenitors came from Africa and 24% from America. Ninety two percent of those SCD patients born in Spain were detected in their first days of life due to universal screening detection implemented in Community of Madrid since 2003. Median age at first diagnosis was 1.42 years (0-21.4). Median age at the end of inclusion was 9.91 years (range 0.13 to 35.14). SS or S/Betathal^0 was reported in 86%. In addition, 2.39% associated alfa gen deletion, and 1 (0.48%) glucose 6 phosphate dehydrogenase deficiency. No patient had congenital thrombotic diathesis. Eighteen patients (8.65%) had human leucocyte antigen (HLA) identical siblings. Hydroxyurea was added to standard treatment in 65 patients (31%) of which 47 continue to be treated to date. Penicillin prophylaxis was communicated in 165 patients (79%). Vitamin-D prophylaxis was initiated in 128 patients (61%). Chronic exchange or simple transfusions existed in 26 cases (12%) and 9 children (4%) underwent splenectomy. None of these patients had sepsis or meningitis. Cholecystectomy was performed in 9 cases (4%). There were 18 progenitor stem cell transplantations (8.61%) performed between 2.09 to 13.97 years of age (median 6.77 years). Ten patients remained on complete chimerism, 6 on mixed chimerism and 1 attained a marrow rejection. One patient died of graft-*versus*-host disease. Patients lost in follow-up summed up 128: 23 for emigrating to other countries, 65 for continuing the monitor of their diseases in other centers or in adults units and 31 for unknown reasons. There were 9 deaths (2.87%).
Summary/Conclusions: Early diagnosis like universal neonatal screening allows an effective health education, and antibiotic and osteopenia prophylaxis with vitamin D and general and specific vaccination can be started.

PB2144

COMPLEMENT ACTIVATION IN PATIENTS WITH SICKLE CELL DISEASE IS ASSOCIATED WITH HIGHER HBS LEVELS

E. Gavriilaki[1,*], M. Mainou[2], I. Christodoulou[2], E.-E. Koravou[1], A. Paleta[1], T. Touloumenidou[1], A. Papalexandri[1], A. Athanasiadou[1], C. Apostolou[2], P. Klonizakis[2], A. Anagnostopoulos[1], E. Vlachaki[2]
[1]Hematology Department - BMT Unit, G. Papanicolaou Hospital, [2]Adults Thalassaemia Unit, 2nd Department of Internal Medicine, Aristotle University of Thessaloniki, Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece

Background: Older studies have suggested activation of the alternative pathway of complement (APC) in sickle cell disease (SCD). Despite the renewed interest in SCD therapeutics, little is known about APC activation in the clinical setting of SCD, possibly due to the complexity of complement diagnostics.
Aims: We investigated firstly, whether complement activation can be detected in the sera of asymptomatic SCD patients using a simple functional assay, secondly whether it is associated with clinical parameters and thirdly whether it can be blocked *in vitro* by the complement inhibitor eculizumab.
Methods: Consecutive asymptomatic SCD patients were enrolled prospectively from November 2016 to January 2017. Patient history, clinical and laboratory data were recorded. Complement activation was detected in patient sera using the modified Ham test, a cell proliferation assay based on the susceptibility of a PNH (paroxysmal nocturnal hemoglobinuria)-like cell line to complement activated serum. Normal human serum (NHS) was used as a negative control and lipopolysaccharides (LPS)-incubated normal serum as a positive control. All samples were tested in triplicates and twice. Eculizumab containing serum (ECU) was collected from a PNH patient within 60 minutes after the infusion and used to test complement blockade by eculizumab in the modified Ham test.
Results: We studied 26 SCD patients (36±11 years of age, 12 male:14 female, 8 HbS/S: 18 HbS/β-Thal). Among them, only 6 had a history of painful crisis and 15 a splenectomy, 15 were on hydroxyurea and 12 on antithrombotic treatment. Based on previous studies and present controls, percentage of non-viable cells higher than 20% was considered a positive modified Ham test, indicating increased APC activation in 4 SCD patients (Figure 1). Positive patients had significantly increased HbS levels (80.5±11 *vs* 61.8±16%, p=0.037), while 2/4 were homozygous (HbS/S) and 2/4 heterozygous (HbS/β-Thal). The majority (3/4) were not on hydroxyurea. No significant difference was found regarding age, gender, platelets, white blood cells, Hb, HbF, LDH and bilirubin levels between patients with and without complement activation. Then, we evaluated *in vitro* the efficacy of complement inhibition by eculizumab in the modified Ham test. Mixing eculizumab serum (ECU) with complement activated sera demonstrated a dose-killing relationship that was consistent across the 4 patients.

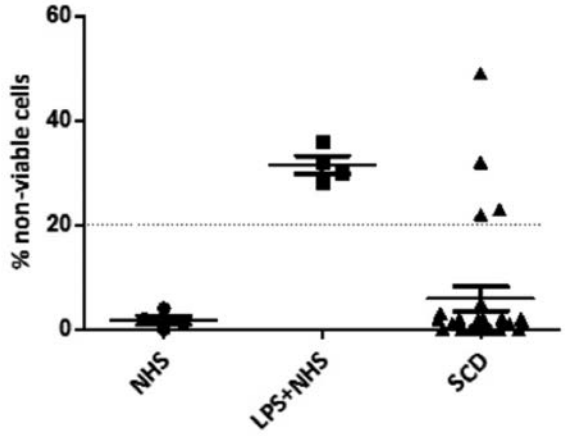

Figure 1.

Summary/Conclusions: Our results suggest that complement dysregulation is evident in asymptomatic SCD patients with increased HbS levels, an important tool in everyday clinical practice. APC activation during a painful crisis and the role of hydroxyurea need to be further investigated in larger series validating the role of different functional assays. Effective inhibition of complement activation *in vitro* is promising for future studies in selected patients.

PB2145

THE ROLE OF EXECUTIVE DYSFUNCTIONS IN THE VERBAL LANGUAGE DEFICITS OF CHILDREN WITH SICKLE CELL DISEASE

B. Arfe'[1], M. Montanaro[2], E. Mottura[2], R. Manara[3], M. Scaltritti[1], G. Basso[2], L. Sainati[2], R. Colombatti[2,*]
[1]Department of Psychology, University of Padova, [2]Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, [3]Department of Radiology, University of Salerno, Salerno, Italy

Background: Children with Sickle Cell Disease (SCD) frequently present impairment of general and specific neurocognitive functions, even in the absence of clear neurological damage at brain neuroimaging. Verbal language deficits are also common, but the etiology of poor performance in the verbal domain is still not clear. The ability to speak and communicate verbally relies on a complex interaction of cognitive and linguistic functions as well as on environmental factors, like bilingualism or second language (L2) learning. The majority of children with SCD in Italy are of immigrant families whose first language is not Italian. These children thus perform poorly in tests assessing the verbal domain with adverse impact on school performances.
Aims: To evaluate if verbal language deficits in bilingual children with SCD are mainly due to linguistic and environmental issues or to impairment of executive functions.
Methods: In this study a cohort of bilingual children with SCD and social-demographically matched healthy controls recruited from elementary schools of the same city, performed an extensive battery of tests to assess naming skills, phonological and semantic fluency, attention and Executive Functions (inhibition and planning skills) and visuo-spatial skills (Boston naming test, phonological and semantic fluency tests, Flanker task, Elithorn test, PMA spatial relations subscale). All tests were administered in Italian. A composite index considering parental education and employment was used to match socially, demographically and economically children at best. Analyses of variance (ANOVAs) were performed to test differences between the two groups in verbal language, attention and executive functions. Hierarchical regressions explored the contribution of linguistic knowledge and executive functions (*i.e.* inhibition) to the verbal language deficit of children with SCD.
Results: Thirty-two children with HbSS SCD aged 6 to 12 years (mean age= 9.03) and 35 controls (mean age= 9.14) were enrolled. Patients and controls were matched for gender (F 53 *vs* 61%), ethnicity (African 30 *vs* 29),% of children born in Italy (81 *vs* 80%), number of years lived in Italy (8.09 *vs* 8.31) and Socio-Demographic Index (5.15 *vs* 4.59). Children's Performance (in Z scores) at Visuo-Spatial, Boston Naming, Phonological Fluency and Semantic Fluency Tests are shown in Figure 1. The results overall showed significant differences between patients and controls in inhibition and planning (p= 0.001 and 0.001 respectively) and in verbal tasks that involved Executive Functions more (*i.e.* phonological fluency) (p=.004). The poorer verbal performance of children with SCD was not associated to visible lesions to Broca's area; in fact only 9 patients presented Silent Infarcts that were all in the white matter, in watershed areas. Regression analyses showed that in children with SCD inhibition skills explained unique variance in phonological fluency, suggesting that poor executive control

was a factor of the lower performance in this task. Figure 1. Children's Performance (in Z scores) at Visuo-Spatial, Boston Naming, Phonological Fluency and Semantic Fluency Tests. P-values: Visuo-spatial intelligence: not significant(ns); Boston naming: ns; Phonol-Fluency: 0.004; Semantic fluency: ns.

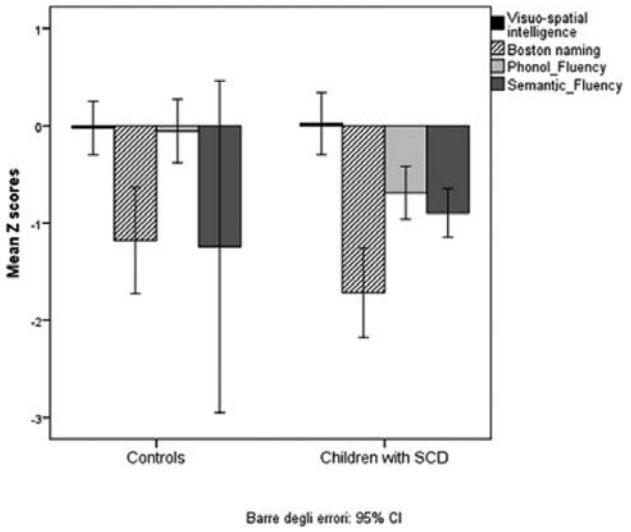

Figure 1.

Summary/Conclusions: Selective language problems may occur in children with SCD in the absence of clear neurological damage to language areas. These problems are explained by the executive dysfunction of patients with SCD and not by environmental factors like bilingualism. Cognitive rehabilitation or extra tuition may aid in overcoming these difficulties.

PB2146

UNDERSTANDING MEDICAL HISTORY, LIFESTYLE AND NEEDS FOR FUTURE THERAPIES FOR PEOPLE LIVING WITH SICKLE CELL DISEASE - IMPLICATIONS FROM A PATIENT SURVEY

A.M. Leitgeb[1,*], M. Robinson[2], C. Herder[1], L. Jendeberg[1]
[1]Modus Therapeutics, Stockholm, Sweden, [2]Micromattie Consulting Inc, Oviedo, Florida, United States

Background: Sickle Cell Disease (SCD) is an inherited blood disorder affecting millions of people. Sevuparin/DF02 is being developed to treat people suffering from SCD and is currently in clinical phase 2 for the treatment of the acute painful crisis in hospitalized SCD patients with intravenous infusion. This is called the Resolve program. In a second program called EASE, sevuparin/DF02 will be investigated as an on-demand treatment of early symptoms of painful sickle cell crisis in an at-home setting via a subcutaneous injection.Searching in the literature and discussing with health care providers, it becomes clear that little is known about how the SCD patients sense these early symptoms of a painful crisis. In order to gain increased understanding of how people living with SCD experience daily life, coping with disease, support by health care providers and the demand for new therapies, a patient survey addressing these areas was conducted.
Aims: The aim with this survey was to gain deeper understanding of different aspects of life with SCD by providing a channel for patients to air their own views. The outcome will provide important information and, in combination with future feasibility studies, will guide the design of the first clinical study aimed at treating the early symptoms of pain crises in SCD patients.
Methods: A 29-question survey was created to gather input on a wide variety of topics related to the lives of people living with SCD. This questionnaire was developed by Modus Therapeutics AB, Sweden, in conjunction with Micromattie Consulting Inc., USA. Experts and leaders of community-based organizations participated in two focus group sessions to ensure that the text and structure were ethical and appropriate for the intended purpose. The survey was hosted at www.modustxpatientsurvey.com. Patients answered the survey directly, or had their views entered in by a caregiver. The answers are anonymous. During the initial period, survey promotion occurred within the Sickle Cell Warriors online community and later, additional connections within the network of community-based organizations were leveraged. The survey was open for access during the period of January 10, 2017 through March 1, 2017.
Results: An interim analysis was conducted on January 31, 2017. Basic demographic data is presented in Table 1. Responders were located mainly in the US. Medical history related questions indicate that fatigue (40%), aches/pain (37%), irritability (27%) and appetite (20%) are early symptoms and increase just before the onset of a pain crises. However, 7% reported infrequent signs and 19% never experienced an indicator of pain crisis. Patients take initiative at home to manage the onset of an acute crisis and the top 5 home strategies reported were: prescription pain medication (15%), sleep/rest (15%), apply heat using heating pad/blanket/bath/shower (13%), increase fluid intake (12%), and finally avoid stress (9%). Further it is clear, that people living with SCD are motivated to try a new therapy that could provide "significant relief" and "prevent symptoms from happening" due to their SCD.

Table 1.

Demographic data from interim analysis January 31, 2017.

Demographic data	
Number of responders	70
Age	4-74 years
Female	80%
Male	20%
SCD diagnosis	100%
Ethnicity	
• African American/African Descent	97%
• Other	3%

Summary/Conclusions: The survey collected feedback about topics for which the patient is the best source of information. It is obvious that people with SCD are willing to self-medicate by subcutaneous injections and that there is a need for new tools and medications. With support from the answers from the survey, specific aspects will be considered while designing a first clinical study for subcutaneous sevuparin/DF02 administration to treat early symptoms of painful crisis in an at-home setting.

PB2147

LONG-TERM USE OF HYDROXYUREA IN CHILDREN AND ADOLESCENTS WITH SICKLE /BETA THALASSEMIA

M. Economou[1,*], A. Teli[1], E. Papadopoulou[1], A. Papastergiopoulos[1], S. Theodoridou[2], F. Papachristou[1]
[1]Aristotle Universtity of Thessaloniki, [2]Blood Bank, Hippokration General Hospital, Thessaloniki, Greece

Background: Hydroxyurea (HU) has lately been used in the treatment of patients with severe sickle cell disease (SCD). Despite documented benefits on laboratory and clinical parameters in SCD patients, there are few reports about drug's long-term safety and efficacy in pediatric patients with SCD – even more so in the rare patient subgroup of sickle/beta thalassemia.
Aims: A prospective, long term evaluation of HU efficacy and safety in children and adolescents with sickle/beta thalassemia (S/b thal).
Methods: Ten patients with S/b thal aged 3.5-18 years were followed for a 6 year period (Jan 2011- Dec 2016). HU was given at a daily dose that ranged from 10 to 20 mg/kg, with a mean of 14.1 mg/kg. Laboratory follow-up consisted of WBC, Hb, Ht, RBC, reticulocyte count and PLT count measured every 2 weeks until dose escalation to a stable dose, biochemistry assessed every 2 months and Hb F measured every 2-3 months. Patients were clinically evaluated prior to HU treatment and every 12 weeks during the study period. Evaluated data on clinical course included frequency of vaso-occlusive crises, hospitalizations and transfusions, as well as presence of severe clinical events. Hematologic toxicity of hydroxyurea was defined as a more than 20% decline from baseline in Hb, as an absolute neutrophil count of less than 1,000/μl and/or a PLT count of less than 80,000/μl. Moreover, presence of alopecia, rash, skin hyperpigmentation or headache was reported as drug-related toxicity.
Results: A significant reduction in vaso-occlusive crises as compared to prior to HU treatment was noted (median: 1 episode per year before HU, range: 0-2.5 *vs* median: 0.24 episodes per study year after HU, range: 0-1.33, p=0.011). A significant reduction in hospitaliizations was also reported (median: 1 per year before HU, range: 0.3-2 *vs* median: 0.16 per study year after HU, 0-0.83, p=0.005). None of the patients presented with severe clinical events such as acute chest syndrome, avascular bone necrosis, stroke or splenic sequestration during the study period. With regards to hematological parameters, a significant increase in HbF (10.2±6.5% *vs* 16.6±7.1% p=0.02), MCV (66.1±3.9fl *vs* 79.3±8.4fl, p<0.001) and MCH (20.9±1.2pg *vs* 25.3±2.2pg, p<0.001), as well as a decrease in reticulocyte count (7.7±3.3% *vs* 5.0±1.9%, p=0.039), WBC count (9,566±3,674/μl, *vs* 7,466±3,460/μl, p=0.009) and PLT count (333,778/μl,±170,227 *vs* 272,111±160,304/μl, p=0.007) was noted. Concerning adverse events, one patient presented with mild transaminasemia, one with mild elevation of serum creatinine levels and one with pancytopenia. Due to persistent pancytopenia HU treatment was discontinued in the last mentioned patient, but was restarted a year later due to frequent vaso-occlusive events - despite the patient being put on transfusions after initial HU discontinuation. Besides the pancytopenia episode, the rest of the mentioned toxicities were short-term and dose-dependant.
Summary/Conclusions: The study indicates that HU has an overall safe profile and results in a marked improvement of clinical course in pediatric S/b thal patients.

PB2148

IN VITRO AND *IN VIVO* EVIDENCES OF SICKLING REVERSAL INDUCED BY REHYDRATION WITH HIGH K+-ISOTONIC SOLUTION

O. I. Ajayi[1,*], O. Uchegbu[2], F. Ozimede[1]
[1]Physiology, [2]Medical Lab Science, University of Benin, Benin city, Nigeria

Background: Erythrocyte sickling and adhesion are favoured by cellular dehydration, which increases the rate of hemoglobin polymerization and cell sickling. Potassium chloride co-transport and calcium-activated potassium channel (Gardos channel) mediate erythrocyte dehydration in sickle cell disease and β-thalassemia. We investigated the in-vitro and in-vivo effects of various concentration of K^+ ions in physiological solutions (PSS) as well as in *cocos nucifera* water (CNw) which is known for its natural high potassium content and isotonicity.
Aims: This study was aimed at ascertain the efficacy of high potassium isotonic solutions in rehydrating sickle cell and possibly reversing the sickling phenomenon at *in vivo* and *in vitro* situations
Methods: : Erythrocytes from twenty sickle cell anaemia (SCA) as well as 46 healthy subjects were studied. One part was treated with sodium metabisulphite ($Na_2S_5O_7$) solution to induce maximum sickling as controls while the other was subjected to different high concentrations of K^+ in PSS as well as *Cocos nucifera* water (40mM, 80mM and CNw - 65mmol/L) respectively. The procedure was repeated for the normal HB AA subjects. Also, both groups of subjects were given 10ml/kg body weight of coconut water to drink as a single dose for the in-vivo experiment. Blood samples were collected longitudinally before and after the oral ingestion, at 1hr and at 24hrs for analysis of red cell indices as well as stained blood films used to ascertain the percentage sickled erythrocytes count before and after the treatment in both cases.
Results: Maximum percentage counts of sickled cells after the addition of $Na_2S_5O_7$ (45%) were observed which decreased significantly ($P<0.05$, respectively) to about 2% with Cocos nucifera and 10% with 80mM K^{+PSS}. The count in 40mM K^{+-PSS} was not statistically significant. In both Hb AA and SS subjects, MCH and MCV remained relatively stable when compared with the pre-ingestion sample ($P>0.05$, respectively) while MCHC increased significantly in both groups as early as 1hr and sustained till the 24th hour. MCHC was equally raised in the in-vitro samples ($P<0.05$, respectively). The morphology of red cells also indicated a lesser count of sickled red cells after the oral ingestion
Summary/Conclusions: *Cocos nucifera* water and other high potassium ion solutions can activate the rehydration of sickled erythrocytes by probably de-activating the Gardos channel to increase the mean corpuscular haemoglobin concentration(MCHC) and thereby restoring the normal red cell shape. We suggest a probable pharmacological value of the *cocos nucifera water* as well as other formulated high potassium but isotonic fluids in SCA management.

PB2149

VITAMIN D IN SPANISH CHILDREN WITH HEMOGLOBINOPATHIES.

A.M. Bobes Fernández[1,2,3,*], B. Ponce[1,2], Y. Aguilar[1,2], C. Garrido[1,2], M. García-Morín[1,2], C. Beléndez[1,2], E. Cela[1,2]
[1]Hospital Gregorio Marañón, [2]Facultad de medicina, Universidad Complutense de Madrid, [3]Hospital Clínico San Carlos, Madrid, Spain

Background: Although vitamin D deficiency has been documented as a frequent problem in studies of children, there are limited data on the prevalence of this nutritional deficiency among children who suffer from sickle cells disease (SCD) or thalassemia. Vitamin D homeostasis is important to prevent osteopenia. Furthermore vitamin D deficiency has been associated with increased risk of common cancers, autoimmune diseases, hypertension, and infectious diseases. Vitamin D deficiency is now recognized as a pandemic. The major cause of vitamin D deficiency is the lack of sun. Although Spain has a high rate of sunny hours, we have found low levels of vitamin D in our patients with SCD or thalassemia.
Aims: The purpose of this work is to assess the status of vitamin D in children with SCD and thalassemia in our setting.
Methods: We have recruited children diagnosed with SCD and thalassemia between 1998 and 2016 and we have reviewed their vitamin D levels. We have chosen the first vitamin value we obtained and the last one till today. Vitamin D was measured by quantitative determination of 25(OH) D. Deficit of vitamin D was defined by<30 ng/ml. The study enrolled 114 children. Most of them, with SCD diagnosis (94%). The type of anaemia was Hb SS (94 patients), Hb SC (8 patients), Hb Sß0 (3 patients) and HbSß+ (2 patients). The remaining 6% were diagnosed with Thalassemia Maior. Mostly of the children were African or Central-South American. In our centre, vitamin D prophylaxis is made since the first year of life.
Results: 60% of the children had vitamin D deficiency. We have divided children into 4 groups depending on the age. When considering vitamin D first determination: mean vitamin D levels in children below 2 years old were 39.5±13.3 ng/dl. The group between two and five years old had a mean serum vitamin D of 35.5±14.8 ng/dl. Children aged between five and ten had 26.1±13.5 ng/dl of mean 25(OH)D. Finally in the group older than 10, we observed mean of 7.4±14 ng/dl. When having these low levels of vitamin D, we strongly recommend to start treatment with Cholecalciferol 25000U/month. Regarding second levels of vitamin D, we have divided patients into those who presumably have the treatment against children who do not. We present the results in the following Table 1.

Table 1.

	<2 years old	2-5 years old	5-10 years old	>10 years old
Vit D treatment	33.7±9.02ng/dl	35.5±12.3ng/dl	34.3±7.3 ng/dl	26.4±11.2ng/dl
No Vit D treatment	-	33.8±1.5 ng/dl	27.3±4.9 ng/dl	6.6±2 ng/dl

Summary/Conclusions: The study found a high prevalence of vitamin D deficiency in children older than five years old(in the first determination) with SCD or Thalassemia Maior and significant decrease of levels in those not having vitamin D therapy. It is not well known the physiopathology of this factor deficiency, although it is supposed to be multifactorial. However we confirm that living in a sunny geographical situation with a healthy diet is not enough to maintain an adequate 25(OH)D levels. Although it is difficult to reach correct levels of vitamin with oral treatment, vitamin D levels increase when having correct doses. We have also checked that older children have lower levels of vitamin D than younger boys. This could be explained by the fact that preteenagers spend lot of time at home instead of going out. If prophylaxis is made not only the vitamin levels will increase but bone growth also.

PB2150

KNOWLEDGE OF SICKLE-CELL DISEASE IN HAUTE-NORMANDIE, SOCIO-DEMOGRAPHIC CONTEXT AND HEALTH CHARACTERISTICS: INTEREST OF THE IMPLEMENTATION OF A PATIENT EDUCATION IN SICKLE CELL DISEASE

S. Ngo[1,*], H. Van Elslande[2], A. Lahary[3], J.-M. Kerleau[4], H. Levesque[2]
[1]Internal Medicine, Hopital Delafontaine, Saint Denis, [2]Internal Medicine, [3]Hematology, CHU Rouen, Rouen, [4]Internal Medicine, Centre hospitalier de Dieppe, Dieppe, France

Background: Sickle cell anemia (SCA) is a genetic disease causing a severe disease manifesting by painful crisis but which can also be marked by organ complications. Mortality is still happening at a young age. Many of these complications may be better taken care of if treated early. The best way to manage this disease is probably through Patient Education (PE)
Aims: Patient Education for children with sickle cell anemia has been a subject of research, organized in France by association such as ROFSED, but PE in adult patients has been little studied. The main objective of this work was to evaluate SCA patients followed in Haute-Normandie, from a sociodemographic, health and socio-demographic perspective in order to establish a PE program. The secondary objective was to give them the opportunity to express their expectations of such a program.
Methods: We did an observational multicenter study. A self-questionnaire of 39 items was sent to all patients suffering from SCA followed in Haute-Normandie.
Results: Fifty patients (male / female ratio 0.92) out of 123 (40.6%) responded, mean age 33±10.5 years (SS genotypes [66%], SC[25%], S-beta-thalassemia [9%]). 56% of them were born outside of Metropolitan France, 36% came from French speaking African countries. Aerage age was 18±10.9 years. Despite the fact that their education has been disrupted by the disease for the majority (69.4%), the level of education was “satisfactory”: 68% of patients had graduated from high school or achieved a higher level, 18% had graduated from professional education, 10% had a primary / middle school level and 4% were illiterate. 68% of the patients had a job or were students. 48% of patients reported to practice physical activity at least once weekly. Tobacco was consumed on a daily basis by 14%, alcohol 2% and 4% for cannabis. Self-assessment of health status was 6.9 / 10, self-assessment of morale of 7.9 / 10 and impact of the disease on daily life was estimated at 5.4 / 10. The mean age at at which specialized follow-up was started was 11±9 years. 88% of the subjects stated that they understood everything the doctor said during consultation. Missed appointments were reported by 26% which was justified by forgetfulness, lack of will or physical incapacity. Regarding sources of information regarding SCA, patients declared asking their specialist first and then looking on the internet. 68% of subjects had a first-degree relative suffering from the same disease, 71% were able to talk about the disease with their family. While the triggers of crises and the management of crises were well-identified by patients (average scores of 13.8 and 12/20), “standards” were not met with chronic complications, prenatal diagnosis, and long term treatment (mean scores respectively of 7.4; 4.2 and 2.2 / 20). Average score on the whole questionnaire was 9/20. Most patients showed interested in PE (52.1%) *vs* 31.3% that claimed were not interested, 17.7% did not decide.
Summary/Conclusions: A majority of SCA adults followed in Haute-Normandie are first-generation migrants. Even if the disease has heavy impact on everyday life and school access, their education level appeared correct. PE sessions will need to focus on chronic complications, prenatal diagnosis, and the long term treatment. The majority of adults with SCA are motivated by PE, we will have to adapt to a heterogeneous population in terms of educational level, ethnic origin and knowledge of the disease.

PB2151

DELAYED HAEMOLYTIC TRANSFUSION REACTIONS: A MASQUERADE OF SICKLE CELL COMPLICATIONS

H.N. Fernandez - Leyva[1,*], S. Kotsiopoulou [1], N. Osuji[1], J. Maitland[1]
[1]Haematology, Croydon University Hospital, london, United Kingdom

Background: Patients with sickle cell disease (SCD) may require repeated red blood cells (RBCs) transfusion, putting them at risk from minor blood group alloimmunization and the development of delayed haemolytic transfusion reactions.
Aims: Reported a prevalence of recognized DHTR syndrome in patients with SCD.
Methods: We reviewed the cases of (DHTR) in SCD patients in a 5-year period (2010- 2016). A total of 10 patients had a clinical picture compatible with DHTR and underwent treatment with high dose steroids, intravenous immunoglobulins (IVIG) or erythropoietin. Any patient received Rituximab.
Results: The most common indications for transfusion were anemia due to vasococlusive sickle cell crisis or preoperative anaemia optimization. The cohort received partial exchange transfusion and phenotypically matched RBCs. Before transfusion the median of Hb level was 69 g/L (baseline range 80g/L) and the nadir at haemolysis episode was 38 g/L, Ht was 21.9%, WBC was 17.3 × 10^9 cells/L and mean LDH 1290 IU/L). The median time to develop DHTR was seven days after the transfusion and approximately 6 days after the surgical interventions (range: 4–12 days) and all cases presented with symptoms of anaemia, jaundice, tiredness and tachycardia. The median age was 29 years with female predominance (6:4). Blood cultures were negative in 80% of patients and only positive in 2 cases. 30% of patients tested positive for viral infection on PCR. Mortality rate in our series was low (zero). Pain episodes and other complications associated with DHTR was treated as required and four cases were successfully monitored in HDU. One patient required noninvasive ventilations and inotropic support. Two patients received RBCs transfusion (median 1.5 unit of packed RBCs). Possibly as their presentation mimics an acute vaso-oclusive crisis. In all cases haemoglobin stabilized and improved, symptoms resolved and patients were discharged on small course of oral antibiotics (median admission 6 days).
Summary/Conclusions: The symptoms of DHTR can easily be mistaken for other SCD complications, including infection and vaso-occlusive crisis.
The diagnosis of DHRT is based on clinical suspicion, when there is a rapid Hb drop after a recent RBC transfusion with clinical signs of haemolysis. To support the diagnosis, laboratory tests (serial FBCs, haemolysis screen, DAT, measurement of Hb S levels) and exclusion of other aetiologies are useful. Whenever a DHTR is suspected, further RBC transfusion should be withheld unless absolutely necessary, as it may precipitate acceleration of the hemolytic reaction. Patients in whom the diagnosis of DHTR is missed may receive repeat transfusions, which may contribute to the complications associated with SCD. The use of more extensive phenotypic matching of blood and minimizing RBC transfusion help to prevent DHTR. The present series emphasize the importance of early recognition of symptoms and signs in correlation with a recent history of RBC transfusions, as DHTR can be a potentially life-threatening complication.

PB2152

HBS MONITORING ON TOSOH G8 IN VARIANT HBA1C MODE IN CASE OF URGENT RCE

S. Van Aelst[1], E. Nackers[1], K. Desmet[12], D. Kieffer[13,*]
[1]Department of Laboratory Medicine, University Hospitals Leuven, [2]Department of Cardiovascular Sciences, [3]Department of Microbiology and Immunology, KU Leuven, Leuven, Belgium

Background: Pre- and post-transfusion HbS levels are used to document the efficacy of red blood cell exchange (RCE) in patients with sickle cell disease (SCD). In case of urgent RCE a 24/7 STAT analysis, with the ability to identify and quantify hemoglobin (Hb) S, is warranted.
Aims: We evaluated the use of Tosoh Automated Glycohemoglobin Analyzer HLC-723G8 (Tosoh Europe, Amsterdam, The Netherlands) for this purpose, using the variant HbA1c mode. Results were compared to our routine CZE Minicap Flex Piercing (Sebia, Lisses, France).
Methods: Within- and between-run imprecision were assessed using a sickle cell trait and a sickle cell anemia sample, aliquoted and stored at -80°C, twice daily in duplicate for ten days. A linearity study was performed using duplicate measurements of a dilution set of 11 samples (HbS range: 0% - 88%). Additionally, a comparison study was conducted between TOSOH G8 and Minicap Flex Piercing using 32 whole blood left-over HbS samples (HbS range: 9% - 93%). Data analysis was performed using Microsoft Excel Analyze-it version 4.65.3 and differences were considered as statistically different if the P-value was <0.05.
Results: Within- and between-run imprecision were <2% and an acceptable linearity was observed. Passing-bablok regression analysis comparing TOSOH G8 and Minicap Flex Piercing showed an acceptable correlation coefficient of 0.998 (>0.95) and a slope and intercept of 0.94 (95%CI: 0.92 to 0.98) and 0.057 (95% CI: -2.5 to 1.3), respectively. Differences in HbS results between TOSOH G8 and Minicap Flex Piercing ranged from -8.76% to +0.36% (mean difference: -3.54%). More specifically, for samples with a HbS concentration <25% HbS results on TOSOH G8 differed between -0.34% to +0.36% compared to Minicap Flex Piercing. For samples with a HbS concentration >25%, differences in HbS results ranged from -8.76% to -0.43%.
Summary/Conclusions: In our clinical laboratory, TOSOH G8 is used in variant HbA1c mode to quantify HbA1c. Previous studies demonstrated reliable HbS identification using TOSOH G8 in variant HbA1c mode. Our study showed a good analytical performance for HbS quantification using TOSOH G8. Good correlation with Minicap Flex Piercing system was found, although results were statistically not interchangeable. Our results suggest that TOSOH G8 in variant HbA1c mode generates lower HbS results in samples with a high HbS concentration (>25%) compared to our routine analyzer. However, the goal of RCE is to achieve a post-transfusion HbS level of 30% or less. Therefore, results obtained with TOSOH G8 are clinically acceptable to monitor post-transfusion HbS levels. Importantly, HbS on TOSOH G8 can only be requested in case of urgent RCE. Our routine hemoglobinopathy screening will still be performed using CZE Minicap Flex Piercing in combination with CE-HPLC Variant ^{II}TM.

GENDER DIFFERENCES IN THE DEVELOPMENT OF CMR ABNORMALITIES AND CARDIAC COMPLICATIONS: A MULTICENTRIC PROSPECTIVE STUDY IN A COHORT OF SICKLE CELL DISEASE PATIENTS

A. Meloni[1,*], L. Pistoia[1], C. Gerardi[2], E. Facchini[3], M. Allò[4], M. P. Smacchia[5], S. Campisi[6], S. Maffei[1], V. Vinci[7], G. Restaino[8], V. Positano[1], A. Pepe[1]
[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Presidio Ospedaliero "Giovanni Paolo II" - Distretto AG2 di Sciacca, Sciacca, [3]Azienda Ospedaliero-Universitaria di Bologna - Policlinico "S. Orsola-Malpighi", Bologna, [4]Presidio Ospedaliero ASL 5, Crotone, [5]Policlinico Umberto 1, Roma, [6]Presidio Ospedaliero "Umberto I", Siracusa, [7]Azienda Ospedaliera "Garibaldi" Presidio Ospedaliero Nesima, Catania, [8]Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, Italy

Background: No data are available in literature about the relationship between gender and the development of CMR abnormalities and/or cardiac complications in sickle cell disease (SCD).
Aims: This prospective and multicentre study aimed to assess if there was an association between gender and risk of cardiac iron overload, heart dysfunction and dilation, left ventricular (LV) hypertrophy, and myocardial fibrosis, assessed by Cardiovascular Magnetic Resonance (CMR), and of cardio-vascular complications in sickle cell disease (SCD) patients.
Methods: We considered 115 SCD patients (58 females, 34.79±13.26 years), consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network. Myocardial iron overload was assessed by the multislice multiecho T2* technique. Biventricular function parameters and atrial areas were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.
Results: Table 1 shows the comparison between sexes in the development of cardiac outcomes. Males and fameles showed a similar risk of accumulating cardiac iron, but both patients with cardiac iron were females. Compared to females, males showed a significant lower risk of developing LV hypertrophy, although having a similar risk for biventricular dilation and dysfunction and for myocardial fibrosis. No patients with less than 31 years developed LV hypertrophy and age at the CMR was significantly higher in patients with LV hypertrophy *versus* patients without it (41.24±75.98 years *versus* 34.47±13.37 years; P=0.003). We recorded 12 (10.4%) cardiac events: 4 ischemic strokes, 5 arrhythmias (4 supraventricular and 1 ventricular), two pulmonary hypertensions and one pulmonary embolism. No prospective association was detected between gender and cardiac complications.

Table 1.

	N(%) with positive outcome	Cox Regression	
		HR (95%IC)	P
Global heart T2<20 ms:*			
Female sex	2 (3.4)	Reference	0.506
Male sex	0	0.02	
Ventricular dilatation			
Female sex	10 (17.2)	Reference	0.162
Male sex	4/55 (7.3)	0.44 (0.14-1.39)	
LV hypertrophy			
Female sex	12 (20.7)	Reference	0.02
Male sex	1/55 (1.8)	0.09 (0.01-0.069)	
Ventricular dysfunction:			
Female sex	12 (20.7)	Reference	0.965
Male sex	11/55 (20.0)	1.02 (0.44-2.37)	
Myocardial Fibrosis:			
Female sex	7/39 (17.9)	Reference	0.338
Male sex	3/35 (8.3)	0.50 (0.12-2.05)	
Atrial dilatation			
Female sex	9/36 (25.0)	Reference	0.990
Male sex	7/32 (21.9)	1.01 (0.37-2.71)	
Cardiac complications			
Female sex	8 (13.8)	Reference	0.204
Male sex	4 (7.0)	0.42 (0.11-1.59)	

Summary/Conclusions: In SCD male and female seem to show a comparable risk in developing cardiac complication, although compared to females, males showed a significant lower risk of developing LV hypertrophy. There are no specific guidelines for SCD patients and, as a consequence, the cardiovascular follow-up is conformed to that one of thalassemia patients (complete cardiac evaluation performed annually for both genders). Our data not support a different follow up time based on the gender.

PB2154

SICKLE CELL PAIN IN CHILDREN: TARGETS FOR ADMINISTRATION OF ADEQUATE INITIAL ANALGESIA

A. Rushd[1,*], A. Ramanathan[2], B. Inusa[3]
[1]KCL, [2]GSTT, [3]Paediatric haematologist, Guys St Thomas Hospital, London, United Kingdom

Background: Acute pain is a hallmark presentation in sickle cell disease (SCD) and frequently requires attendance to the emergency department (ED).
Aims: Here we report our findings following a complete retrospective audit cycle, documenting the timeliness of analgesia administration and post-treatment pain review as per National Institute of Clinical Excellence and College of Emergency Medicine guidelines, in children with SCD presenting to a single inner city London ED over a 14 month period.
Methods: In 2014, we evaluated 48 patient records of children presenting to the ED, with respect to mild, moderate and severe pain scores, time of analgesia administration and pain review. Completing the audit cycle, 97 records were re-audited in 2015. A total of 145 admission records were evaluated.
Results: In 2014 the ED met CEM criteria for the timeliness of analgesia administration in 100% of severe and 95% of the moderate pain category; however fell 33% short of NICE standards. Pain review was poorly performed, identifying an area for improvement. Proportions meeting the aforementioned criteria fell significantly in 2015, except review of moderate pain, which increased by 25%.
Summary/Conclusions: We conclude CEM guidelines promote timely administration of analgesia in patients with severe pain; however mild pain may be overlooked. NICE avoids this discrimination. Thus we recommend combining the mild and moderate pain categories to acknowledge the fluctuating nature of sickle pain and its tendency to rapidly escalate. In addition, we reiterate the need for regular pain reviews. This is important in ensuring analgesia is closely titrated to pain level.

PB2155

DIAGNOSTIC CHALLENGES IN A POPULATION WITH INCREASED IMMIGRATION: HEMOGLOBINOPATHIES IN THE NEW CENTURY

J. Zanabili Al-Sibai[1,*], A. Fonseca Mourelle [1], T. Arias Fernández[1], L.R. Morais Bras[1], L.F. Ávila Idrovo[1], C. Castañón Fernández[1], A. Solé Magdalena[1], A. Bernardo Gutiérrez[1], R. Llorente de Jesus[1]
[1]Hematology, HUCA, Oviedo, Spain

Background: The diagnosis of hemoglobinopathies (Hbpts) has changed in recent years due to immigration, with an increase in structural Hbpts. In our region, Asturias, population census is 1,061.756 habitants; 48,097 out of them are immigrants.
Aims: Review the incidence of structural Hbpts and thalassemias in our region in the last 10 years.
Methods: A retrospective analysis was performed with 1202 hemoglobin (Hb) studies at Hospital Universitario Central de Asturias between January 2006 and March 2016. The studies came from medical applications, the finding of abnormal Hb patterns in the HbA1c test or suggestive results of thalassemia on hematimetry test. Studies were performed by high-performance liquid chromatography (HPLC) with the Variant Hemoglobin Testing machine of Bio Rad, and Hb electrophoresis with Paragon plates until May 2013. Since then, it has been performed by capillary electrophoresis (CE) with the MINICAP System of the Sebia laboratory.
Results: We analyzed 1202 patients, 49% were males and the median age was 33 years (range 0-85). We found 562 patologic studies. - Thalassemia were detected in 390; 337 were β or δβ (86.4%); 54% came from Spain. The cases of β-thalassemia were: 5 intermedia, 3 major, 1 δβ-homozygote and the remainder were minor (97%). All thalassemia major, 3 intermediate and 74%of minor were Caucasian. Anemia was found in all of major thalassemia (median Hb 6.2g / dL, range 6-6.5), in 3 of intermedia (11.4g / dL, range 6-10), and in 197 of minor (10.87g / dL, range 6.9-11.9). - Structural Hbpts were found in 170, the predominant was Hb S (n=125). Only 17 sickle cells (Hb SS and Hb SC). Most of them black (n=14) coming from Africa (n=10) and South America (n=5). Eighty six percent (n=108) were heterozygous (Hb SA), mainly from Africa (n=56) and South America (n=23). Anemia were seen: 4 Hb SC (median Hb 10.5g / dL, range: 9.4-11.2), 9 Hb SS (7.94g / dL, range 5.2-9.7) and 37 heterozygotes (10.15g / dL, range 6.7-11.9). There are two peaks of higher incidence of structural Hbpts, in 2008 coinciding with the creation of the Tropical Diseases Unit and since 2013 when detection increases with the introduction of HbA1c test. The increase in thalassemias was due to the decision to extend studies due to pathological findings in hematimetry results (Figure 1).

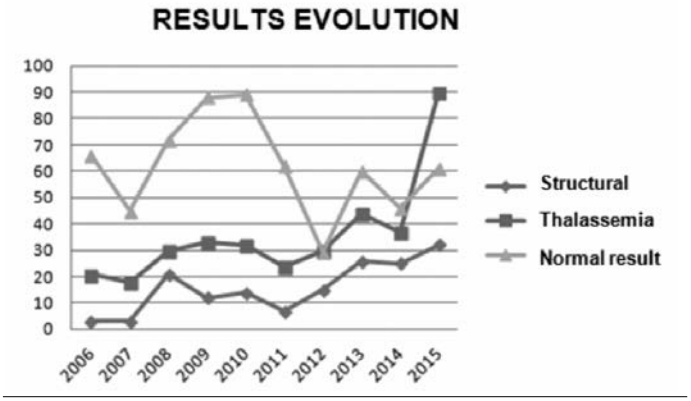

Figure 1.

Summary/Conclusions: In our area there is a predominance of β-thalassemia minor. Structural Hbpts are the main diagnosis in immigrants. The incidence is still small, although increasing in the last 3 years, so a neonatal screening program is being implemented. Both HPLC and EC are simple, fast and efficient methods in the diagnosis of Hbpts. In our area there is a predominance of β-thalassemia minor. Structural Hbpts are the main diagnosis in immigrants. The incidence is still small, although increasing in the last 3 years, so a neonatal screening program is being implemented. Both HPLC and CE are simple, fast and efficient methods in the diagnosis of Hbpts.

EFFECT OF SUSTAINED-RELEASE SUPPLEMENTATION OF L-ARGININE AMONG CHILDREN WITH SICKLE CELL DISEASE IN FEDERAL TEACHING HOSPITAL GOMBE, NORTH EASTERN NIGERIA

O. Erhabor[1,*], V.D. Knox[2], S. Abubakar[3], S. Yuguda[3]
[1]Haematology and Blood Transfusion Science, Usmanu Danfodiyo University Sokoto, Nigeria, Sokoto, Nigeria, [2]Department of Biochemistry and Molecular Pharmacology, West Virginia University Medical School , Morgantown, United States, [3]Department of Haematology, Federal Teaching Hospital Gombe, Gombe State, Nigeria , Gombe, Nigeria

Background: Sickle cell disease is a global public health problem. As of 2013 about 3.2 million people have sickle-cell disease with 176,000 deaths
Aims: In this present study, we investigated the effect of 8 weeks, low dose supplementation of sustained-release of nitric oxide generating L-arginine supplement (350mg) given two times daily on the full blood count, L-arginine, nitric oxide, Pantothenic acid, plasma malondaldehyde, glutathione and total antioxidant capacity of children with sickle cell disease.
Methods: This study included children with sickle cell disease (HbSS) aged 1-14 years with mean age 7.4500±0.50613 years presenting to the sickle cell clinic unit of Federal Teaching Hospital Gombe, Gombe State. Subjects received sustained release oral L-arginine supplementation of 350mg twice daily for 8 weeks.
Results: L-arginine and nitric oxide levels were significantly higher among sickle cell disease children. There were no statistically significant differences between the baseline and post L-arginine supplementation in the PCV, WBC, RBC and LYM levels of subjects ($p>0.05$). There was a statistically significant difference between the baseline and post L-arginine supplementation in the MCV, MCH, MCHC, PLT, NEU, EOS, MON and RDW-SD levels of subjects ($p<0.05$). The L-arginine and nitric oxide levels was significantly higher post supplementation compared to baseline levels ($p=0.002$ and 0.000 respectively). The pantothenic acid level was significantly higher at baseline compared to post supplementation levels ($p=0.00$). The L-arginine, nitric oxide and Total Antioxidant Capacity was significantly higher post supplementation compared to baseline levels among sickle cell disease subjects with vaso-occlusive crisis ($p= 0.001$, 0.01 and 0.05 respectively). The pantothenic acid and malondaldehyde levels at baseline were significantly higher than the post supplementation levels among subjects with vaso-occlusive crisis ($p=0.002$ and 0.000 respectively). The Total Antioxidant Capacity and Glutathione levels were significantly higher post supplementation compared to baseline levels among the sickle cell subjects ($p= 0.05$ and 0.000 respectively). The baseline plasma malondaldehyde level was significant higher that the post supplementation levels among the sickle cell disease subjects. There is need for more effort and resources to be dedicated to research especially in supplementation studies involving a larger population aimed at establishing specific treatment for sickle cell disease. It is recommended that L-arginine supplementation be included in the management of patients with sickle cell disease particularly those with vaso-occlusive crisis. We observed a statistically significant negative correlation between the L-arginine levels and the red cell count among sickle cell disease subjects ($r= -0.350$, $p=0.043$).

Summary/Conclusions: L-arginine supplement should be made available in the paediatric emergency unit, clinic and pharmacy department in high risk communities to obviate the negative effects during vaso-occlusive crisis and potentially reduce the length of stay in the hospital. L-arginine, nitric oxide, total antioxidant capacity, malondaldehyde and glutathione levels should be routinely monitored in sickle cell disease patients particularly those presenting with vaso-occlusive crisis.

Saint-Justine, University of Montreal, Montreal, Canada, [11]Hematology Department, Hospital Infantil Universitario Nino Jesus, Madrid, Spain, [12]Institute of Hematology and Oncology Paediatrics, Hospices Civils de Lyon, Lyon, France, [13]Hospital Sírio Libanês, San Paulo, Brazil, [14]Division of Stem Cell Transplantation and Immunology, Hospital for Children and Adolescents of Frankfurt, Frankfurt, Germany

Background: Body mass index (BMI) may influence outcome after allogeneic transplantation. Previous studies have demonstrated that being obese or underweight may have a detrimental effect on survival rates after chemotherapy induction in children with acute leukemia. However, the impact of BMI of transplanted patients on survival is still not clear, with conflicting results being reported on this issue.
Aims: To analyze the effect of BMI on UCBT outcomes in children with acute leukemia
Methods: We retrospectively analyzed 517 patients aged from 2 to 20 years with acute leukemia who underwent umbilical cord blood transplantation (UCBT) from 1990 to 2015. Patients were classified according to BMI as normal (5^{th}-85^{th} percentile), underweight (<5^{th} percentile), overweight (85^{th}-95^{th} percentile) and obese (>95^{th} percentile) by using growth charts for age and gender.
Results: Sixty-one percent (n=314) of patients were in the normal category, 12% (n=63) were underweight, 15% (n=80) overweight and 12% (n=60) obese. All patients received single-unit UCBT after a myeloablative conditioning regimen. Diagnosis was acute lymphoid leukemia in 70% (n=363) and acute myeloid leukemia in 30% (n=154). Median age at UCBT was 7.4 years (range 2-19.6). Cytomegalovirus (CMV) serology was positive in 45% patients; 60% of patients were male. Most patients (92%) were in complete remission at UCBT. Median follow-up was 52 months (range 2-201). Total body irradiation (>6 Gy) was used in 58% of cases; antithymocyte globulin (ATG) in 68% of cases. Median infused total nucleated cell (TNC) dose was $4.2x10^7$/Kg (0.3-17.8); 56% of patients received a graft with 0-1 HLA mismatch donor. Four-year overall survival (OS), leukemia-free survival (LFS) and graft-*versus*-host disease-free, relapse-free survival (GRFS) were 45±2%, 43±2% and 35±2%, respectively. Cumulative incidence function (CIF) of neutrophil engraftment was 88.6% (85.9-91.4%). CIF for acute GVHD was 34% (30.1-38.4%) at 100 days. At 4 years chronic GVHD was 19.1% (15.7-23.3%), relapse incidence was 34.5% (30.1-38.9%) and non-relapse mortality (NRM) was 22.8% (19.2-26.7%). In univariate analysis, no statistically significant difference in OS, LFS, GRFS, neutrophil engraftment, NRM and chronic GVHD between the 4 groups identified according to BMI was identified. Conversely, acute GVHD was 44.3% (33.3-58.8%) for underweight, 36% (31-41.8%) for normal, 26.2% (18.1-38%) for overweight and 23.3% (14.7-37.1%) for obese (p=0.03). Among patients underweight who experienced acute GVHD (n=27), 37.5% had grade III-IV acute GVHD with gut involvement. In multivariate analysis, infused TNC dose>$4.2x10^7$/Kg was associated with higher neutrophil engraftment (HR=1.46, CI 95% 1.18-1.82, p=0.001). Positive CMV serology (HR=1.5, CI 95% 1.04-2.26, p=0.03) and female gender (HR=1.5, CI 95% 1.03-2.23, p=0.03) were associated with higher NRM. ATG use (HR=1.6, CI 95% 1.05-2.31, p=0.03) was associated with higher relapse incidence. Moreover, ATG use and a positive CMV serology were associated with worse OS (HR=1.6, CI 95% 1.15-2.17, p=0.04 and HR=1.3, CI 95% 1.01-1.69, p<0.001, respectively) and LFS (HR=1.6, CI 95% 1.17-2.16, p<0.001 and HR=1.34, CI 95% 1.04-1.72, p=0.02, respectively). Infused TNC >$4.2x10^7$/Kg (HR=1.5, CI 95% 1.07-2.14, p=0.02), lack of ATG in the conditioning (HR=2.72, CI 95% 1.6-3.1, p<0.001) and BMI <5^{th} percentile (HR=1.8, CI 95% 1.19-2.78, p<0.001) were associated with higher incidence of acute grade II-IV GVHD.
Summary/Conclusions: In conclusion, we did not find association of obesity with transplant outcomes in this study population. However a BMI <5^{th} percentile at UCBT was found to be associated with higher risk of acute GVHD, highlighting the importance of nutritional status before UCBT.

PB2158

PROSPECTIVE PHASE STUDY OF REDUCED TOXICITY CONDITIONING CONSISTED OF HIGH DOSE-CYTARABINE, FLUDARABINE, CYCLOPHOSPHAMIDE +/- TOTAL BODY IRRADIATION FOLLOWED BY ALLOGENEIC STEM CELL TRANSPLANTATION

S. Kasahara[1,*], H. Nakamura[2], Y. Kaneda[1], Y. Ikoma[2], E. Takada[3], Y. Shibata[1], T. Matsumoto[2], N. Nakamura[2], S. Ninomiya[2], J. Kitagawa[2], H. Goto[1], T. Hara[2], M. Sawada[3], T. Takahashi [1], K. Saito[4], M. Shimizu[2], H. Tsurumi [2]
[1]Hematology, Gifu Municipal Hospital, [2]Hematology, Gifu University Graduate School of Medicine, [3]Hematology, Gifu Red Cross Hospital, [4]Internal Medicine, Gihoku Kosei Hospital, Gifu, Japan

Background: Allogeneic hematopoietic stem cell transplantation (allo-SCT) using reduced intensity conditioning (RIC) has been widely applied to elderly or frail patients who are not eligible for conventional conditioning regimen. However, benefit provided by reduced toxicity has been often offset by increased incidence of relapse. So far, the optimal conditioning for those patients has not been established.
Aims: Here, to investigate whether addition of high dose cytarabine (AraC) to RIC regimen consisting of fludarabine (Flu) and cyclophosphamide (Cy) +/- total body irradiation (TBI) can be available for elderly or frail recipients, phase II study has been designed.
Methods: This study was conducted from April 2011 to December 2015. The protocol was approved by each institutional review board (Trial identifier: UMIN000007281). Patients aged from 55 to 70, or patients who have some organ damage or a history of SCT aged from 20 to 54 with hematologic malignancies were enrolled after obtaining written informed consent. Bone marrow (BM), peripheral blood (PB), or cord blood (CB) was used as stem cell sources. Pretransplant conditioning regimen consisted of 30 mg/m^2 of Flu for 5 days (total 150 mg/m^2), 4 g/m^2 of AraC for 2-4 days (divided by 2 daily, total 8-16 g/m^2) and 50mg/kg of Cy for a day. Four gray of TBI was used for all CB transplant recipients, whereas 2 gray of TBI was used in other stem cell sources except a matched related donor according to each institutional policy. Calcineurine inhibitors (cyclosporine or tacrolimus) and short term methotrexate were used as GVHD prophylaxis. Donor cell engraftment and 60 day-survival were assessed as a primary end point to evaluate feasibility of this protocol.
Results: Thirty nine patients including 7 recipients with a history of SCT were enrolled. Median age was 61 (28-69), 21 were male, and 18 were female. Nineteen were acute myeloid leukemia, 11 myelodysplastic syndrome, 6 malignant lymphoma and 3 acute lymphoblastic leukemia. Donors were 4 matched related PB, 8 matched unrelated BM, 5 1-Ag/allele-mismatched unrelated BM, and 22 ≤2-Ag-mismatched CB. Thirty seven (94.9%) patients have passed 60-day-point post-transplant. In 38 (97.4%) recipients, engraftment was obtained, a patient died before engraftment due to sepsis caused by enterococcus faecium (male CB recipient, 55y, day15). Median neutrophil recovery to over 500/μl was obtained on day 19 (16-38). Fourteen blood stream infections (13 bacteremias and 1 candidemia) judged as grade 3 toxicity and 2 cases (1 sepsis and 1 endotoxemia) of grade 4 toxicity were observed within 60 days post-transplant. There were 2 deaths of post-engraftment due to cerebral bleeding (1 female CB recipient, 64y, day 46) and GVHD (1 male CB recipient, 60y, day 77) within 100 days. Although no relapse was observed up to day 60, 7 relapses were observed up to 1 year. Overall survival and disease-free survival were estimated to be 82.1% and 73.8% at 1 year post-transplant, respectively.
Summary/Conclusions: RIC using Flu/high dose AraC /Cy +/- TBI was well tolerated with acceptable low toxicities and was sufficient to allow donor cell-engraftment post allo-SCT for elderly or frail patients with hematologic malignancies. Longer follow up and another prospective study enrolling more patients are required to evaluate the eventual survival benefit by reducing relapse.

LATE COMPLICATIONS OF CONDITIONING REGIMENS (CYCLOPHOSPHAMIDE - TOTAL BODY IRRADIATION *vs* BEAM) FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN NON-HODGKIN LYMPHOMA.

S. Novelli[1,*], A.C. Caballero[1], A. Monter[1], G. Gomez Segura[2], I. Garcia Cadenas[1], A. Esquirol[1], R. Martino[1], J. Sierra[1], J. Briones[1]
[1]Hematology, [2]Radiotherapy, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Autologous stem cell transplantation (ASCT) is a frequently used procedure for the treatment of patients with relapsed non-Hodgkin lymphoma (NHL). While chemotherapy-based regimens are now commonly administered, total body irradiation (TBI) was largely used in the past. The current conditioning regimen in our center is BEAM (a combination of carmustine (BCNU), etoposide, cytarabine and melphalan) allthough we also have a large experience with cyclophosphamide (CFM)-total body irradiation (TBI) since this was the usual conditioning until year 2000.
Aims: To analyze the cumulative incidence of secondary neoplastic complications and non neoplastic complications (grade 3-4 infections, cardiovascular and pulmonary toxicity) after the two conditioning regimens (CFM-TBI *vs* BEAM) for ASCT.
Methods: We performed a retrospective analysis of patients with NHL that received an ASCT between October 1992 and December 2012. The late complications were defined as those to other previous comorbidity or to aging. Statistical analysis was performed using the IBM SPSS Statistics version 21.0. Cumulative incidences were estimated using EZR version 1.27 (Saitama Medical Center, Jichi Medical University, Omiya, Japan), a graphical user interface for R (version 3.1.1).
Results: A total of 105 atografted patients were analyzed. Patient's characteristics are in Table 1. The median follow up since ASCT was 73 months (0 – 274 months). Thirty-one percent (n=33) of patients were conditioned with CFM-TBI. The overall 5-years survival (OS) was 68.3% (58-77% - CI 95%) and the 5-year disease free survival (DFS) was 52% (42 61% - CI 95%). There were no differences regarding OS and DFS between the two conditioning regimens. The 5-years cumulative incidence (CI) of relapse was 0.48 (0.37-0.57, CI 95%). We detected 10 secondary neoplasm (myelodysplasia n=1, skin carcinoma n=2, lung carcinoma n=3, oropharingeal carcinoma n= 1, intestinal adenocarcinoma n=1, renal neoplasia n=1, bladder neoplasia n=1). The median time for the neoplastic event was 10.5 years (0-18.5 years). The CI of secondary neoplasias (2nd neoplasia) at 10 years was 10% (1-20%, CI 95%) and at last point of follow up (18.5 years) was 40% (13%>63%, CI 95%). There were no differences in the CI of 2nd neoplasias between BEAM and CFM-TBI. Non-neoplastic complications were present in 10% of patients (n=11). Three cases were infections grade 3-4 related to ASCT. Six cases had cardiac complications (5 acute coronary syndrome, 1 myocardiopathy) and 2 had pulmonary toxicity. The CI of non-2nd neoplastic complications at 10 year was 10% (1 – 25%, CI 95%).No differences were detected between the two conditioning regimens regarding non-neosplastic complications. (see Figure 1).

Table. 1. Patient's characteristics.

	Frequency (n)	Percentage
Age (years)	51 years old (18-70 years)	
Gender	Male: 62	59%
Histology	Diffuse Large Cell Lymphoma: 40	38%
	Follicular Lymphoma: 65	62%
Prognostic Index (IPI or FLIPI) (when available, n=103)	Low risk: 23; Intermediate risk: 67; High risk: 13	22%/65%/13%
Response pre- ASCT	Complete Remission: 58	55%
	Partial Remission: 46	44%
	Stable disease: 1	1%
Number of Lines pre-ASCT	1 line: 11; 2 lines: 69; 3 lines: 18; 4 lines: 7	10%/66%/17%/7%
Conditioning	CFM-TBI: 33 ; BEAM: 74	31% / 69%

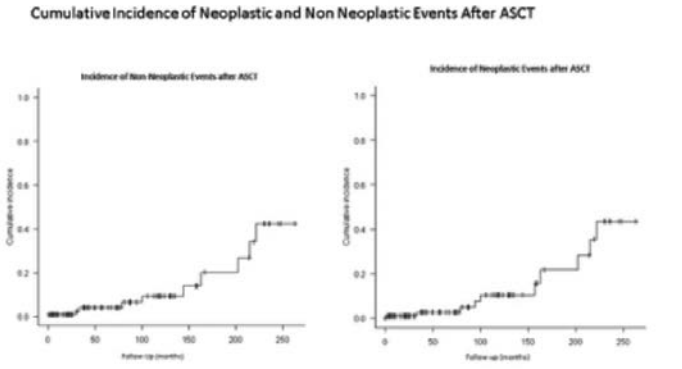

Figure 1.

Summary/Conclusions: Autologous stem cell transplantation offers long disease free survival for half of the patients with a high risk non-Hodgkin lymphoma. In our series, patients conditioned with BEAM or CFM-TBI had a comparable incidence of neoplastic and non-neoplastic events

PB2160

THE MANAGEMENT OF RELAPSED HODGKIN´S LYMPHOMA AFTER HAPLOIDENTICAL STEM CELL TRANSPLANTATION: DONNOR LYMPHOCYTE INFUSION AND BRENTUXIMAB.

I. Sánchez Bazán[1,*], A.L. Contento Gonzalo[1], M.J. Pascual Cascón[1], A.R. Martín Cerezo[1], M.Á. Cuesta Casas[1], A.I. Heiniger Mazo[1]
[1]Hematology, Hospital Regional de Málaga, Málaga, Spain

Background: Hodgkin's lymphoma, is an heterogeneous malignancy wich is posible to cure. For those patients who relapse, chemotherapy followed by an autologous transplantation (autoTPH) may conduce to a complete remission. Allogeneic transplantation (alo-SCT) is used for patients in relapse after auto-SCT or those with refractory advanced disease. Since 2012, with the experience of the Baltimore group, our Center has chosen the haploidentical family donor as a source for aloSCT in Hodgkin's disease. Despite the promising results, the rate of relapse is between 25 and 35%, and there is not standardized treatment for this situation.
Aims: To analyze the outcome of post-transplant relapse treatment of haploident donor haematopoietic progenitors (haploTPH).

Methods: We studied 18 patients with the diagnose of Hodgkins lymphoma in our center between August 2004 and July of 2013. All of them were submitted to haploSCT with a median follow-up of 495 days (455-1054).
Results: The median age was 32 years (21-60). 44% (8 patients) relapsed. 60% of then (5 patients) were nodular sclerosis histological subtype and 40% (3) lifocitic predominance. 2 patients (25%) were diagnosed in stage IV and 75% (6) stage II. The median of number of treatment lines received before transplantation was 5.5 (4-7); Compared to 7 in the non-relapsed group (4-11). 5 patients (60%) of the patients who relapsed had reached haploTPH in complete remission and 40% in partial remission, we did not observe differences related to the pre-SCT status. Peripheral blood was used as progenitors source in 75% (6) of the patients who relapsed and in 70% (7) in the non-relapsed group. 38% of the whole group of patients, had a donor/recipient KIR alloreactivity without differences between the two groups of the study. 88% (7) of the relapses occurred before 6 months of the SCT. The mean time to relapse was 316 days (range 181-446). Between the 8 relapsed patients, one was treated by another center with Vimblastine / Dexamethasone and died by infection, another patient died by abdominal sepsis before starting any treatment. Brentuximab was administered in 63% (5) of the patients. One of them received a single Brentuximab cycle with no tolerance, and changed to RT, GPD+Donnor lymphocyte infusions (DLI) and had reached complete response after 5 DLI. The rest (4) received between 3 and 7 doses with adequate tolerance. According to the the re-evaluation (PET-TC) after 3rd Brentuximab, 4 were in partial remission and one reached complete response. We associated Donor lymphocyte infusion in 6 patients. The mean of DLI received was 10; the median was 8, with a range between 22-3. Four patients reached complete remission, two of them maintain a partial response. All of them presented good tolerance to DLI. We observed Graft *versus* host disease in four patients, 3 of them presented moderate cutaneous affection, and one of them suffered hepatic graft *versus* host disease stage III, with adequate evolution after treatment.
Summary/Conclusions: Is posible to treat patients who relapsed after haploidentical stem cell transplantation with Brentuximab+DLI, with a very good tolerance. We observed cutaneous graft *versus* host disease in most of the patients who reached completed response after DLI. Despite this findings, we need multicentric studies to perform standarized treatments and protocols.

PB2161

CONDITIONING REGIMENS BEFORE AUTOLOGOUS STEM CELL TRANSPLANT FOR PATIENTS WITH MALIGNANT LYMPHOMA – LEED *vs* MCEC –

H. Shimizu[1,*], C. Naitoh[2], Y. Osaki[1], Y. Miyazawa[3], K. Toyama[2], H. Koiso[1], A. Yokohama[1], M. Morio[3], H. Ogura[4], N. Tsukamoto[1], H. Handa[1]
[1]Gunma University, Maebashi, Gunma, [2]Fujioka General Hospital, Fujioka, Gunma, [3]Shibukawa Medical Center, Shibukawa, Gunma, [4]Maebashi Sekijuji Hospital, Maebashi, Gunma, Japan

Background: High-dose chemotherapy before ASCT has been established as an effective treatment option for high-risk patients with chemo-sensitive ML. Although the therapeutic efficacy of this strategy highly depends on the conditioning regimens before ASCT, the appropriate regimen has been controversial. Thus, we performed a multi-center retrospective study of ASCT recipients with ML to compare the safety and efficacy of the conditioning regimens LEED and MCEC, which are widely used in Japan.
Aims: The primary objective was to determine the preferable conditioning regimen before ASCT: LEED or MCEC.
Methods: This study analyzed 127 adult patients who underwent ASCT following LEED or MCEC as the conditioning regimen against chemo-sensitive ML at four institutions in Japan between 1997 and 2015. Any type of pathological diagnosis was considered. The LEED regimen consisted of 140 mg/m^2 L-PAM (day −1), 500 mg/m^2 etoposide (days −4 to −2), 60 mg/kg cyclophosphamide (days −4 to −3), and 40 mg/body dexamethasone (days −4 to −1). The MCEC regimen consisted of 200 mg/m^2 MCNU (days −8 and -3), 300 mg/m^2 carboplatin (days −7 to −4), 500 mg/m^2 etoposide (days −6 to −4), and 50 mg/kg cyclophosphamide (days −3 to −2). Fisher's exact test was used to compare binary variables. OS rates were estimated by the Kaplan-Meier method and compared using the log-rank test. Cumulative incidences (CIs) of relapse and non-relapse mortality (NRM) were compared using the stratified Gray test. The Cox proportional hazards regression model was used for multivariate analysis of OS. Values of p <0.05 were considered significant.
Results: Of the 127 patients, 76 were male and 51 were female, and the median age was 56 years (range: 18 to 68 years). Underlying diseases were DLBCL in 74 patients, mantle cell lymphoma in 16, other B-cell lymphoma in 14, Hodgkin lymphoma in 9, and T-NK-cell lymphoma in 14. The disease status at the time of transplant was first complete remission (CR) in 68, advanced CR in 27, and partial remission in 32. As the conditioning regimens before ASCT, 81 patients (64%) received the LEED regimen, and 46 (36%) received the MCEC regimen. No significant differences in patient characteristics, disease features, or transplant procedures were present between the two groups except for the following three factors: (1) ASCT in the later period (2007–2015) in the LEED group compared with the MCEC group (72% *vs* 13%; p <0.01); (2) more frequent administration of rituximab before ASCT in the LEED group (84% *vs* 59%; p <0.01); and (3) less frequent radiation therapy before ASCT in the LEED group (17% *vs* 37%; p=0.02). The 5-year OS rates were not significantly different between the LEED and MCEC groups (77% *vs* 68%; p=0.35). Likewise, both the 5-year CIs of relapse and NRM were similar in the two groups (relapse: 39% *vs* 33%; p=0.61, NRM: 1% *vs* 5%; p=0.71). In multivariate analysis that included the transplant periods, rituximab administration, and radiation therapy as independent variables, two or more prior regimens was extracted as an independent unfavorable prognostic factor for OS, but not conditioning regimens. Regimen-related toxicities within 100 days after ASCT were assessed. The incidences of grade 3-4 nausea (36% *vs* 78%; p <0.01), vomiting (4% *vs* 28%; p <0.01), diarrhea (36% *vs* 56%; p=0.02), and liver dysfunction (4% *vs* 36%; p <0.01) were significantly decreased in the LEED group. The 5-year CIs of secondary MDS/AML were similar between the two groups (4% *vs* 3%; p=0.62).
Summary/Conclusions: Our findings demonstrated that both the LEED and MCEC regimens showed sufficient anti-lymphoma effect as conditioning regimens before ASCT, with a 5-year OS rate of more than 70% in patients with chemo-sensitive ML. However, the LEED regimen is considered more preferable in comparison with the MCEC regimen based on the low frequency of severe regimen-related toxicities. A large-scale prospective study is warranted to confirm these findings.

PB2162

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR SECONDARY HAEMATOLOGICAL NEOPLASIA: A SINGLE CENTER EXPERIENCE

E. Metafuni[1], P. Chiusolo[1], L. Laurenti[1], F. Sorà[1], S. Giammarco[1], G. Leone[1], A. P. Bacigalupo[1], S. Sica[1,*]
[1]Hematology Department, Fondazione Policlinico agostino Gemelli, Rome, Italy

Background: Therapy related haematological neoplasms (t-HN) occur due to direct mutational events of chemotherapeutic agents and radiotherapy. Disease latency, mutational events and prognosis vary with drugs categories.
Aims: The aim of this retrospective study was to assess the outcome of t-HN after hematopoietic stem cell transplantation (HSCT).
Methods: We describe a cohort of 31 patients, 19 females (61.3%) and 12 males (38.7%), with median age of 53 years (range, 20 to 64), who received an allogeneic HSCT in our Unit, between September 1999 and July 2016. Patients had a history of solid tumor in 15 cases (48.4%), haematological malignancies in 15 cases (48.4%) and both of them in one case (3.2%). All but one received a median of 2 (range, 1 to 6) lines of therapy. After a median of 36 months (range 12-190) from the first neoplasia, patients developed t-AML (n=19) (61.3%), t-Ph+ ALL (n=1) (3.2%), or t-MDS (n=11) (35.5%). Molecular abnormalities were detected in 7 (46.7%) out of 15 evaluable patients: BCR/ABL (1), ITD FLT3 (2), inv16 (1), NPM1 (2), NPM1+/ITD FLT3 (1). Karyotype aberrations were found in 18 (64.3%) out of 28 evaluable patients: 16.7% was favourable risk (n=3), 27.8% was intermediate risk (n=5) and 55.5% was adverse risk (n=10). The disease status at transplant was as follows: complete remission (n=13) (42%), refractory disease (N=10) (32%), stable disease (n=3) (10%). Patients received conventional chemotherapy in 14 cases (45.2%), azacytidine in 11 cases (35.5%), both of them in one case (3.2%), whereas 5 patients (16.1%) were untreated. The conditioning was myeloablative (MAC) in 20 patients (64.5%) or reduced intensity (RIC) in 11 patients (35.5%); the donor was a family member (REL) in 17 patients (54.8%) or unrelated (MUD) in 14 patients (45.2%). The hematopoietic cell transplantation comorbidity index (HCT-CI) was as follows: 14 patients (45.2%) had a score of 3 and 17 patients (54.8%) had a score of 4 or more. Overall survival was calculated with Kaplan-Meier method. Transplant-related mortality (TRM) and relapse-related mortality (RRD) rates were estimated by cumulative incidence (CI), both considering the opposite event as competing. Fine and Gray's method for CI of TRM and RRD was used to evaluate the risk factors on univariate analysis.
Results: Twenty-three patients were in remission on day +30, by bone marrow cytology, 3 patients were classified as resistant disease and five patients were not evaluable because of early death. Five patients (21.7%) relapsed after a median 6 months (range, 3 to 15). At the time of this analysis (December 2016) 14 patients were alive with a median OS of 53 months (range 8-190), while 17 patients died after a median of 4 months (range 1-27): RRD was 16% (n=5) and TRM was 39% (n=12). Non relapse causes of death were as follows: GvHD (n=3), infectious complications (n=8) and EBV-related PTLD (n=1). One patient experienced a third tumor (breast cancer) thirteen years from HSCT. TRM was higher for patients transplanted from MUD (66%) as compared to REL donor (16%) (p=0.01). The overall survival was 45.2% (Figure 1) and 58% maintained a complete remission.
Summary/Conclusions: This report confirms that allogeneic HSCT is a curative approach in approximately 50% of patients with therapy related haematological neoplasms, especially for those patients who benefit from a familial donor.

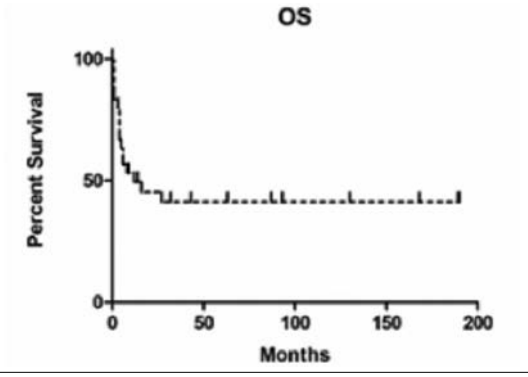

Figure 1.

IMPROVEMENT IN BIVENTRICULAR CARDIAC MECHANICS NOTED IN PATIENTS UNDERGOING MYELOABLATIVE AUTOLOGOUS-HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR AL AMYLOIDOSIS

S. Heitner[1,*], C. Purtell[2], E. Scott[3]
[1]Knight Cardiovascular Institute, [2]Department of Medicine, [3]Knight Cancer Institute, Oregon Health and Science University, Portland, United States

Background: Primary amyloidosis (AL) is characterized by extracellular deposition of insoluble protein fibrils often with multisystem organ involvement. The Mayo staging model for determining prognosis in patients with cardiac amyloidosis takes into account troponin, NT-proBNP, and serum free-light chain difference in order to stage patients prior to undergoing autologous hematopoietic stem cell transplant (Auto-HCT). Since amyloidosis often involves the kidneys, serum biomarkers that require renal clearance are less reliable in the setting of significant renal dysfunction. 2D-echo and strain imaging offer non-invasive modalities for identifying early cardiac changes independent of renal function. These changes may also precede symptom improvement as assessed by NYHA classification.
Aims: Our hypothesis is that strain imaging is a feasible biomarker for cardiac respone after Auto-HCT in AL amyloidosis.
Methods: Seven patients with biopsy-proven AL amyloidosis who were treated with a Melphalan based myeloablative regimen and Auto-HCT were evaluated retrospectively. Each patient underwent 2D-echo up to 36-days prior to treatment followed by repeat 2D-echo within 14-months. Strain imaging was performed using EchoInsight®. Chart review was conducted to determine associated NYHA functional classification and Mayo staging. Statistical analysis was performed using SPSS.
Results: Of the 7 patients studied, 3 were Mayo stage I, 2 stage II, 1 stage III, and 1 stage IV. The median follow-up from transplant was 47.4 months. There was one death at 20.4 months. The mean NYHA classification at baseline was 2.3 and after transplant was 1.9. Longitudinal, radial and circumferential left ventricular strain (LV) were evaluated, but only the global longitudinal strain (GLS) showed an improvement (baseline -14.69%; follow-up -16.84%; mean absolute improvement 2.15%; p <0.05) across all four Mayo Stages. There was no difference in GLS within individual stages. In patients with stable NYHA classification after transplant, there was also a significant improvement in Right Ventricular Free-Wall Strain (RVFWS) with a mean absolute improvement of 6.2% (p <0.05). There was no significant change in left ventricular ejection fraction (LVEF) (Figure 1).

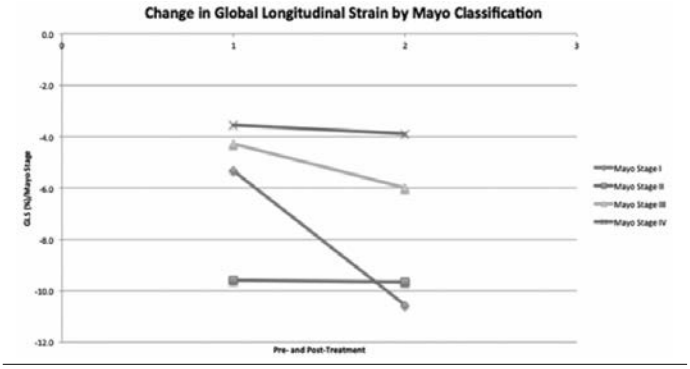

Figure 1.

Summary/Conclusions: We demonstrate that there is a clinically meaningful improvement in cardiac mechanics one year after Auto-HCT, despite no alteration in LVEF. This metric may prove useful in assessing organ response, especially when serum biomarkers are less reliable. Changes in left ventricular GLS occur independent of pre-transplant Mayo stage, although prospective studies are needed for confirmation. We further believe that improvements in RVFWS may predict clinical improvement.

PB2164

AN ABSOLUTE NUMBER OF CD34+ CELLS IN BLOOD AS A PREDICTOR OF A SUCCESSFUL HARVEST OF HEMATOPOIETIC STEM CELLS IN DIFFERENT MOBILIZATION REGIMENS

I. Galtseva[1,*], Y. Davydova[1], T. Gaponova[1], N. Kapranov[1], L. Kuzmina[1], V. Troitskaya[1], E. Zvonkov[1], E. Parovichnikova[1], L. Mendeleeva[1], V. Savchenko[1]
[1]Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Autologous stem cells transplantation (ASCT) has become necessary part in therapy of hematological diseases. Transfusion of at least 2×10^6 CD34+ HSCs per kg of patient's weight allows achieving an adequate hematopoiesis after high-dose chemotherapy. The most optimal is to collect $\geq2\times10^6$ CD34+ cells/kg with single harvest apheresis. Different mobilization regimens lead to variations in white blood cell count (WBC) and the number of circulating HSCs. Deciding on the time of the first leukapheresis is very important.
Aims: The aim was to identify significant parameter predicting efficiency of CD34+ cells collection.
Methods: The study included 142 patients (pts) who undergo ASCT (80 m, 62 f, median age 53 y.o., 81 were diagnosed with multiple myeloma, 10 - Hodgkin's lymphoma, 51 – non-Hodgkin's lymphomas). WBC and absolute CD34+ number in the blood before the first apheresis and the number of CD34+/kg in the apheresis product were determined for each patient. There were three different mobilization regimens: 12 pts received 10 μg/kg/day G-CSF in the stable hematopoiesis for 5-6 days; 86 pts - 4 g/m^2 cyclophosphamide and 5-10 μg/kg/day G-CSF (Cph+G-CSF); 44 pts - DHAP: 40 mg dexamethasone, 100 mg/m^{2}cisplatin, 2g/m^{2}cytarabine and 10 μg/kg/day G-CSF (DHAP+G-CSF). CD34+ HSCs were evaluated with ISHAGE-protocol by BD FACSCanto II flow cytometer. Results are presented as mean±SEM. ROC-analysis was performed for WBC and the absolute number of CD34+ HSCs in the blood as the predictor markers for HSCs successful harvesting ($\geq2\times10^6$ CD34+/kg for fist apheresis).
Results: WBC mean was higher in pts with G-CSF mobilization scheme compared to Cph+G-CSF and DHAP+G-CSF (28.5±3.5 *vs* 10.4±0.9 and $9.0\pm1.8\times10^9$/l, respectively, p<0.0001), but the absolute number of CD34+ HSCs in the blood (26.3±9.3 *vs* 55.5±5.6 and 93.1±22.3/μl, p=0.03) and the number of CD34+/kg in the leukapheresis product (1.9±0.7 *vs* 5.2±0.6 and $6.9\pm1.3\times10^6$/kg, p=0.01) were lower. Differences between Cph+G-CSF and DHAP+G-CSF in all parameters were not found. There was not any relationship between WBC and the number of CD34+/kg: the area under ROC-curve (AUC) didn't differ from 0.5 for all mobilization regimens. Then absolute number of CD34+ in blood was investigated as predictor for harvest success, AUCs were 0.964, 0.938 and 0.979 (p<0.0001) for G-CSF, Cph+G-CSF and DHAP+G-CSF, respectively. In the ROC-analysis showed the optimal CD34+ number in blood than most likely to collect $\geq2\times10^6$ CD34+/kg for first leukapheresis. It was 29 CD34+cells/μl in G-CSF mobilization, 24 CD34+cells/μl – in Cph+G-CSF and 27 CD34+cells/μl - in DHAP+G-CSF. To calculate universal level of absolute CD34+ number all data from 142 pts was used. In this case AUC was 0.952 and a threshold of successful harvesting was 20 CD34+cells/μl in blood before apheresis with sensitivity of 96% and specificity of 81%.
Summary/Conclusions: Various mobilization regimens differ in count of leucocytes and CD34+ HSCs in peripheral blood: WBC was significant higher in G-CSF than in Cph+G-CSF and DHAP+G-CSF, but the absolute number of CD34+ cells was higher in chemotherapy-based mobilization and G-CSF than in G-CSF alone. The absolute number of leucocytes in blood before apheresis was not a predictor factor of harvest success in all variants of mobilization regimens. If there is at least 20 CD34+cells/μl in blood before apheresis it is possible to collect $\geq2\times10^6$ CD34+/kg for single leukapheresis with high sensitivity and specificity independent of mobilization regimen.

QUANTIFICATION OF CD34+ CELL AND ITS VIABILITY OF FRESH OR CRYOPRESERVED NUCLEATED CELLS BY IMAGE-BASED CELL COUNTER IS COMPARABLE TO STANDARD FLOW CYTOMETER

Y.-H. Lee[1,2,*], W.-J. Rah[1], H. Koh[1,2], J.Y. Suh[2], H.J. Eom[2], E.-K. Shin[1], J. Uhm[2,3], J.H. Oh[4], J.-Y. Lee[4], S.R. Bong[4], J.Y. Kim[4], S. Han[4], C. Chung[4], H.J. Park[4], J.K. Yoon[4]
[1]Department of Pediatrics, [2]Blood & Marrow Transplantation Center, [3]Department of Internal Medicine, Hanyang University Medical Center, [4]NanoEntek, Seoul, Korea, Republic Of

Background: As a standard method for quantification of CD34+ stem cells, flow cytometry has been widely used. However, it has some limitations such as

expensive instrumentation, high reagent costs, and poor reproducibility between technicians and laboratories.
Aims: We developed and assessed an instrument performance of a newly-developed image-based microscopic cell counter (ADAM II™) for enumeration of CD34+ cell and its viability.
Methods: We used samples of fresh and cryopreserved nucleated cells from G-CSF mobilized peripheral blood stem cells (PBSCs) as well as cord blood (CB). We assessed the reproducibility and linearity of the new device and compared numbers and viabilities of CD45+ cells and CD34+ cells determined with the ADAM II™ and flow cytometer.
Results: Each analysis used 10 aliquots from one sample to assess the reproducibility of ADAM II™, with expected values of 14.77~172.06 CD34+ cells/, 0.08~0.56 CD34(%)/CD45. The number of CD34+ cells determined by ADAM II™ was sufficiently accurate over the expected range, and the intra-assay coefficient of variation (CV) was ≤10.8%. The linearity of CD34+ cell counts was confirmed over a range of dilutions (0.58~280 cells/□ of sample). Linearity was satisfactory (R^2=0.99). The numbers and viabilities of CD45+ cell and CD34+ cell obtained with the ADAM II™ were highly correlated with those obtained with the flow cytometer (R^2>0.9841, p<0.0001). In all samples from fresh/cryopreserved PBSC and fresh/cryopreserved CB, there were no significant differences of total numbers and viabilities of CD45+ cell and CD34+ cell count analyzed from ADAM II™ as well as flow cytometer.
Summary/Conclusions: The newly developed image-based microscopic cell counter (ADAM II™) appears to be suitable for quantification of CD34+ cell and its viability of fresh or cryopreserved PBSCs or CBs.

PB2166

EXTRACORPOREAL PHOTOPHERESIS IN STEROID-DEPENDENT OR REFRACTORY ACUTE GRAFT-*VERSUS*-HOST DISEASE

I. Sakellari[1], I. Batsis[1], E. Gavriilaki[1,*], A. Panteliadou[1], A. Lazaridou[1], K. Leontopoulos[1], D. Mallouri[1], A. Bouinta[1], V. Constantinou[1], E. Yannaki[1], C. Smias[1], A. Anagnostopoulos[1]
[1]Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: Extracorporeal photopheresis (ECP) has been incorporated in the management of graft-*versus*-host disease (GVHD) post allogeneic haematopoietic cell transplantation (alloHCT) in many centres. The introduction of ECP as an early second-line treatment in steroid-dependent or refractory patients with acute GVHD (aGVHD) remains under study. The rationale of its early use is based on the low incidence of complete responses to corticosteroids and the profound immunosuppression caused by traditional secondary treatments.
Aims: Based on our long-lasting experience in chronic GVHD, we aimed to prospectively assess the role of ECP in this high-risk population.
Methods: We enrolled consecutive patients with steroid-dependent or refractory grade (gr) II-IV aGVHD post alloHCT from January 2013 to August 2016. All patients with unrelated or haploidentical donors received thymoglobulin (ATG) 5mg/kg as prophylaxis. Post-transplant GVHD prophylaxis included cyclosporine – methotrexate in myeloablative and cyclosporine – mycophenolate mofetil in reduced toxicity or intensity regimens. ECP was commenced after assessment of response to 5 days of steroid treatment according to our protocol: 2 sessions/week for 1 month, 1 session/2 weeks for 3 months, evaluation of response and 1 session/month for 6 months.
Results: We studied 20 patients, aged 35 (18-65), post alloHCT with myeloablative (14), reduced toxicity (4) and intensity (4) conditioning, from sibling (3), matched (8) or one locus mismatched (8) volunteer unrelated and haploidentical (1) donors. Disease risk index was high (10), intermediate (9) and low (1). Acute GVHD was observed at day +17 (8-50) in 15 patients, late-onset at+130 (110-160) in 4 patients and induced at +38 post donor lymphocyte infusion in a relapsed AML patient. Skin, intestine and liver involvement was evident in 6 patients, skin and intestine in 10 and skin only in 4 patients. Nine patients (2 with GrII, 7 with GrIII aGVHD) were steroid-dependent and 11 (8 with GrIII, 3 with GrIV) steroid-refractory. ATG was administered simultaneously with ECP initiation in 6 refractory patients that further developed EBV reactivation (p=0.032) treated pre-emptively with rituximab. ECP was commenced at day +51 for 16 (4-20) sessions. The majority of patients (16/20) presented partial (6), very good (9) or complete (1) response to ECP. With 9.3 (1.8-54.7) months of follow-up, immunosuppression was reduced in 10/20 and ceased in 1 patient. Clinically significant bacterial infections were found in 17 patients, fungal in 2, CMV and EBV reactivation in 14 and 13 respectively and other viral in 5 patients. Cumulative incidence (CI) of chronic GVHD was 77.4 at 1-year. 1-year CI of aGVHD-related mortality was 20%. 1-year overall survival (OS) was 53% and significantly increased in steroid-dependent *versus* refractory patients (76% *vs* 36%, p=0.041). Reduction of immunosuppression (p=0.026) and steroid dependence (p=0.023) were associated with improved OS, irrespectively of other factors.
Summary/Conclusions: Our study supports that ECP should be considered early in the course of steroid-dependent or refractory aGVHD, before significant irreversible end organ damage has been established. Optimal timing of intervention, frequency, duration and tapering schedule of ECP need to be investigated in future studies.

PB2167

RAPID RECONSTITUTION OF NK1 CELLS IS ASSOCIATED WITH THE LOWER INCIDENCE OF GRAFT-*VERSUS*-HOST DISEASE AFTER ALLOGENEIC TRANSPLANTATION

X. Zhao[1,*], L. Xu[1], X. Yu[1], Y. Chang[1], X. Huang[1]
[1]Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: The balance between immunostimulation and immunoregulation in T cell immunity is achieved by a Th1/Th2/Th3/Tr1 and CD4+CD25+ regulatory T (Treg) cell paradigm.
Aims: We investigated the production of type1 (IFN-*gamma*, NK1), type2 (IL-13, NK2), type3 (TGF-*beta*, NK3) and regulatory cytokines (IL10, NKr) from human peripheral blood to discuss the cytokine paradigm of NK cells in human allogeneic hematopoietic stem cells transplantation (allo-HSCT).
Methods: Forty patients undergoing haploidentical (n=27) and HLA-identical sibling (n=13) allo-HSCT between August 2009 and December 2009 were enrolled in this analysis after being originally selected using a protocol exploring the association of reconstituted donor derived NK1/NK2/NK3/NKr cells to GVHD and CMV reactivation.
Results: Expansion of NK2 and NK3 were found post allo-HSCT compared to healthy donor. The levels of NKr reconstituted to donor's level since day 15 post allo-HSCT, and the levels of NK1 in recipients post transplantation were consistently lower compared to donors' levels until day 60 post allo-HSCT. Multivariate analysis showed that the higher levels of NK1 by day 15 were associated with lower overall acute GVHD (HR 0.157, 0.039-0.642, P=0.010) as well as II-IV acute GVHD (HR 0.260, 95%CI, 0.064-1.053, P=0.059). Meanwhile, the higher levels of NK1 by day 15 correlated with lower CMV reactivation (HR 0.040, 0.005-0.348, P=0.003).
Summary/Conclusions: These results indicate that rapid reconstitution of NK cells; especially NK1 cells would be help to prevent the development of graft-*versus*-host disease as well as CMV reactivation after allogeneic transplantation.

PB2168

BORTEZOMIB FOR STEROID-REFRACTORY RITUXIMAB AUTOIMMUNITY AFTER ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION

M. Zine[1,*], T. Khalid[1], S. Kafka[1], D. Bonney[1], S. Hughes[1], S.H. Lum[1], R. Wynn[1]
[1]Bone Marrow Transplant Unit, Royal Manchester Children's Hospital, Manchester, United Kingdom

Background: Therapy of post-transplant autoimmunity manifestations remains a challenge. Many cases are steroid and rituximab refractory and continuing intensified immune suppression increase the risk of infection in the post-HSCT patient. In our institution, we have used bortezomib as our third agent after failure of steroids or rituximab, or in cases of steroid-dependence since Bortezomib appears to be effective in cases with refractory autoimmunity.
Aims: In our series, we assessed the therapeutic response to proteasome inhibitor in 4 cases of post-transplant refractory autoimmunity
Methods: Three of the 4 cases received Bortezomib for autoimmune cytopenia (autoimmune haemolytic anaemia AIHA (n=2), AIHA with acquired red Cell Aplasia (n=1)). At least 2 therapy lines had failed to resolve the cytopenia. One to two courses of Bortezomib were administered at a dose of 1.3 mg/m2 at day 1, 4, 8, 11 each course. In two cases this treatment was combined with immunosuppressive agents: Mycophenolate mofetil (MMF) alone in one case and associated with sirolimus in the other case.
Results: Resolution of autoimmune cytopenia was observed in the three cases after a median of 33 days from the first day of administration. The fourth case received 1 course of Bortezomib for persistent anti-enzyme antibodies after allogeneic transplant for Wolman disease. Therapeutic response was obtained after 25 days reflected by a complete regression of circulating anti-enzyme antibodies. In all cases, no Bortezomib related toxicity was noticed. The response was maintained in all cases.
Table 1 summarizes the clinical data and the results of the four cases.

Table 1.

patients	Age at Allogeneic HSCT	Diagnosis	post-transplant bortezomib indication	Previous treatments	bortezomib courses (n)	Response	Time to response	bortezomib-related toxicity	loss of response at last follow up
1	14	Beta thalassemia	AIHA	IVIG, Sirolimus, Steroids, Rituximab, Cyclophosphamide, Splenectomy	2	Yes	33	None	No
2	91	myelodysplastic syndrome trisomy 8	AIHA	IVIG, Steroids, Rituximab, MMF	2	Yes	57	None	No
3	14	Mucopolysaccharidos type 1	AIHA with Acquired Red Cell Aplasia	Rituximab, MMF	1	Yes	14	None	No
4	25	Wolman disease	Anti-enzyme antibodies	None	1	Yes	25	None	No

Summary/Conclusions: Our study shows that Bortezomib is a promising therapeutic option for refractory post-transplant autoimmunity with high tolerance and no related toxicities.

PB2169

POST-THAW CELL COUNT PREDICTS ENGRAFTMENT RATE IN CORD BLOOD TRANSPLANTATION

K. Isobe[1,*], K. Koh[1], R. Kawakami[1], T. Itabashi [1], M. Yanagi[1], K. Sasaki[1], K. Watanabe[1], M. Mori[1], Y. Arakawa[1], R. Hanada[1]
[1]Hematology/Oncology, Saitama Children's Medical Center, Saitama, Japan

Background: The infused cell count in cord blood transplantation (CBT) is an important element for engraftment; however, this number in the prior reports has been based on the pre-thaw cell count. Therefore, the association between post-thaw cell count and engraftment rate, especially in pediatric patients, is unclear.
Aims: Tte Aim of this study is to reveal the association between post-thaw cell count and engraftment rate in pediatric patients in the setting of CBT at our institution.
Methods: We retrospectively reviewed the medical records of 78 patients who underwent CBT between June 1998 and April 2016. We excluded the cases of CBT that required rescuing after engraftment failure.
Results: Underlying disease was acute leukemia (AL) in 63 (ALL, 38; AML, 25) patients, chronic myeloid leukemia in one, malignant lymphoma (ML) in two, myelodysplastic syndrome (MDS) in three, aplastic anemia in one, and others (such as primary immunodeficiency syndrome) in eight. In terms of conditioning regimens, myeloablative conditioning was administered to 62 patients and reduced intensity conditioning was administered to 16 patients. The median age at CBT was 3 (range, 0–19) years, and the median follow-up period was 898 (range, 47–6236) days. The engraftment rate was 84.6%, primary engraftment failure was observed in 11 patients (AL,seven; ML, one; MDS, one; neuroblatoma, one; and others, one) and secondary graft failure was observed in one patient (severe congenital neutropenia). The 3-years overall survival rate was 55.1%, and 32 patients had died (cause of death: progressing disease in 19 patients). We analyzed the data on 34 patients of whom both of pre- and post- thaw CD34+ cell counts in the cord blood samples were available. The median pre- and post-thaw CD34+ cell counts was 1.67×10^5/kg and 1.51×10^5/kg, respectively, and they were significantly correlated with each other (r=0.73, p=0.52). In our study cohort, the engraftment failure occurred in five patients (primary in all patients). The median post-thaw CD34+ cell count was 1.60×10^5/kg in the patients who achieved engraftment and 1.01×10^5/kg in the patients who did not achieve engraftment. No statistically significant difference was observed between these two groups (p=0.30). When we defined the cut-off value of the pre-thaw CD34+ cell count as 1.2×10^5/kg in the patients who were infused with CD34+ cells more than the cut-off value, the specificity and sensitivity of graft failure was 79.3% and 60%, respectively. When we defined the cut-off value of the post-thaw CD34+ cell count as 0.7×10^5/kg in the patients who were infused with CD34+ cells more than the cut-off value, the specificity and sensitivity of graft failure was 96.6% and 40%, respectively.
Summary/Conclusions: We concluded that the risk of graft failure is more precisely predicted by the post-thaw than pre-thaw CD34+cell count and that if the post-thaw CD34+ cell count is more than 0.7×10^5/kg, the risk of graft failure is very low.

PB2170

COLONYFORMING CAPACITY OF HEMATOPOIETIC STEM CELLS MOBILIZED INTO PERIPHERAL BLOOD WITH VINIRELBINE AND GRANULOCYTE COLONY STIMULATING FACTOR

V. Balashova[1], I. Kostroma[2,*], I. Zapreeva[2], V. Rugal'[1], S. Bessmeltsev[2], A. Chechetkin[2], S. Gritcaev[2]
[1]Laboratory of Leukemia Study, [2]Hematological Clinic, Russian Institute of Hematology and Blood Transfusion, St. Petersburg, Russian Federation

Background: One of the alternative method to mobilize stem cells from bone marrow to peripheral blood is using of vinorelbine with granulocyte colony stimulating factor (G-CSF). The specific features of vinorelbine are absence of hospitalization necessity and predictability of leukocytapheresis' optimal time. But there is not enough data to conclude whether vinorelbine is safe for haematopoietic stem cells.
Aims: The aim of the study was to determine the colonyforming capacity of haematopoietic stem cells mobilized into peripheral blood with vinirelbine and G-CSF.
Methods: Data of 11 patients with multiple myeloma (MM) and 1 patient with Hodgkin lymphoma (HL) were analyzed. Vinorelbine was injected IV in dose 50-70 mg (35 mg/m^2). Daily lenograstim dose was 10 mcg/kg. The number of BFU-E, CFU-GM, CFU-GMME and CFU-Macrophage was studied in 14-days culture: $1x10^5$ cells of leukocytapheresis product were set into Petri dish with MethoCult H 4435 full medium. Control group was consisted of hematopoietic stem cells donors' data in which G-CSF monotherapy was used for mobilization.
Results: The median patients' age was 55 (43-64) y. Induction courses for MM treatment included borteszomibe (11 patients), lenalidomide (5 patients) and carfilsomibe (1 patient) in combination with steroids. A patient with HL was treated with ABVD scheme. Leukocytaphereses were started on 6-8 day, herewith in 9/11 (75%) patients on 7 day. The number of gained CD34$^+$ was 1.7-7.8x10^6/kg (Me 3.3x10^6/kg). Median number of BFU-E, CFU-GM, CFU-GMME and CFU-Macrophage in patients' group was 207, 180, 14 and 9 accordingly. The results were not significantly different from control group data: 168, 170, 10 and 12 accordingly; p<0.05.
Summary/Conclusions: We conclude that mobilization regimen with vinorelbine in combination with G-CSF does not damage colonyforming capacity of hematopoietic stem cells.

PB2171

URIC ACID LEVEL MIGHT BE A PROGNOSTIC INDICATOR FOR SURVIVAL IN PATIENTS WHO UNDERWENT ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION. SINGLE CENTER EXPERIENCE

N. Mandaci Şanli[1,*], S. Şıvgın[1], L. Kaynar[1], B. Eser[1], M. Çetin[1], A. Ünal[1]
[1]Hematology and Bone Marrow Transplant Center, Erciyes University School of Medicine, KAYSERİ, Turkey

Background: Uric acid (UA) is an abundant aqueous antioxidant that accounts for almost two thirds of all free-radical-scavenging activity in human serum. It is released from injured cells during conditioning for allogeneic hematopoietic stem cell transplantation (AHSCT).
Aims: The aim of this study was to evaluate the prognostic impact of pre transplantation uric acid levels on survival and mortality in allogeneic HSCT patients.
Methods: We retrospectively analyze 273 patients with hematologic diseases undergoing AHSCT. The patients were categorized as patients with acute leukemia, myelodysplastic syndrome, lymphoma patients and other hematologic disease diagnoses. A serum uric asid concentration 3.4 mg/dl was considered hypouricemia. Pretransplantation uric asid, creatine, total protein and albumin were analyzed. Univariate, multivariate Cox regression models and Kaplan–Meier curves were performed to uric asid, creatine, total protein and albumin associated with disease-free survival (DFS) ,over all survival (OS), early non relaps mortality (+30 day) and late non relaps mortality (+100 day).
Results: Pretransplantation low uric acid levels were detected in 57 (%20.8) patients. Low UA levels were significantly associated with DFS (HR: 0.52; p= 0.027) . None of the creatine, total protein and albümin were significantly associated with DFS (HR:0.98; p= 0.98, HR :0.87 p=0.60, HR: 1.15; p= 0.66). There was no significant association between UA, creatine, total protein and albümin levels and overall survival (HR: 0.84; p= 0.46, HR: 2.10; p= 0.057, HR :0.88; p= 0.52, HR: 0.78; p= 0.26), early relapse mortality (HR: 1.38; p=0.54, (HR: 2.16; p= 0.29, HR: 0.61; p= 0.25, HR: 0.53; p= 0.13) and late non-relapse mortality (HR:0.57; p=0.35, HR: 0.21; p=0.29, HR: 1.04; p= 0.94, HR: 1.07; p= 0.92).
Summary/Conclusions: Uric asid is a natural antioxsidant compound. UA reacts with oxygen-derived free radicals and becomes oxidized. Since humans are unable to catabolize UA to the more soluble compound allantoin due to lack of urate oxidase or uricase, the serum UA concentration is higher in humans than almost all other mammals. However, this high UA level in humans has been regarded as being beneficial in the presence of elevated oxidative stress. Our study supports that the uric asid is a antioxidant compound. BecauseDisease-free survival is lower in patients with low uric acid levels before transplantation. This is the first report demonstrating a positive association between UA levels and survival analyses in allogeneic HSCT patients. Our findings are potentially clinically relevant. Confirmation in independent cohorts and further investigations into underlying mechanisms, such as reduced antioxidative capacity in hypouricemia, are warranted. In thecoming years, as a result of increased works on this subject, uric asid may be considered a possible prognostic marker in allogeneic hematopoietic stem cell transplantation.

PB2172

RISK FACTORS FOR HERPES SIMPLEX VIRUS-1/2 VIREMIA AND CLINICAL OUTCOMES FOLLOWING UNMANIPULATED HAPLOIDENTICAL HAEMATOPOIETIC STEM CELL TRANSPLANTATION

F.-F. Tang[1], L.-P. Xu[1], X.-H. Zhang[1], H. Chen[1], Y.-H. Chen[1], X.-D. Mo[1], Y.-Q. Sun[1], K.-Y. Liu[1], X.-J. Huang[1,*]
[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: Herpes simplex virus(HSV)-1/2 can still be reactivated after allogeneic haematopoietic stem cell transplantation (allo-HSCT) even when the prophylactic acycloviris used. However, the risk factors for HSV-1/2 viremia and the clinical outcomes following unmanipulated haploidentical HSCT remain unknown.
Aims: The aim of this study was to explore the risk factors for HSV-1/2 viremia and to evaluate clinical outcomes following haplo-HSCT.
Methods: Nineteen patients with HSV-1/2 viremia and fifty-seven patients without HSV-1/2 viremia which were selected using the case-pair method after haploidentical HSCT were enrolled. We analysed the risk factors for HSV-1/2 viremia and compared clinical outcomes between the two patient groups.
Results: The risk factors for HSV-1/2 viremia included HLA disparity ≥2 loci (p=0.049) and cytomegalovirus (CMV) reactivation (p=0.028). The incidences of platelet engraftment, oral mucositis and severe haemorrhagic cystitis (HC) in patients with and without HSV-1/2 viremia were 77% and 94% (p=0.003),

78% and 13% (p=0.000), and 25% and 6% (p=0.04), respectively. Moreover, the median time to platelet engraftment in patients with and without HSV-1/2 viremia was 25 d(range,11–80 d) and 17 d(range, 8–67 d) (p=0.004). In a multivariate analyses, HSV-1/2 viremia was associated with delayed platelet engraftment(p=0.038), a higher incidence of oral mucositis(p=0.000) and severe HC (p=0.038). However, HSV-1/2 viremia was not associated with non-relapse mortality (34.0% *vs* 31.5%, p=0.26),leukaemia-free survival (60.9% *vs* 57.9%, p=0.46) and overall survival (61.2% *vs* 60.7%, p=0.37) (Figure 1).

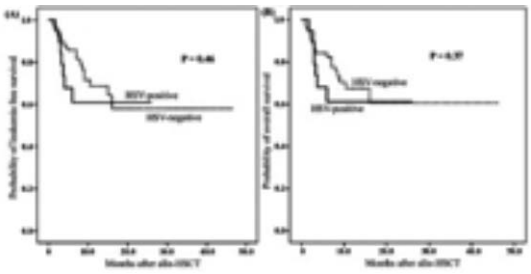

Figure 1.

Summary/Conclusions: Based on our study results, we recommend that HSV-1/2 PCR should be performed on clinical suspicion.

PB2173

FACTORS PREDICTING GRAFT-*VERSUS*-HOST DISEASE-FREE, RELAPSE-FREE SURVIVAL AND OUTCOMES AFTER REDUCED INTENSITY ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE LEUKEMIA OR MYELODYSPLASTIC SYNDROMES

H. Kanamori[1,*], J. Aoki[1], A. Negoro[1], S. Koyama[1], T. Tachibana[1], H. Nakajima[2], M. Tanaka[1]
[1]Hematology, Kanagawa Cancer Center, [2]Hematology and Clinical Immunology , Yokoham City University, Yokohama, Japan

Background: Reduced intensity allogeneic stem cell transplantation (RIST) is now commonly applied for elderly patients with acute leukemia (AL) or myelodysplastic syndromes (MDS). However, the factors affecting graft-*versus*-host disease-free, relapse-free survival (GRFS) and overall survival (OS) remain obscure.
Aims: To identify such factors and to clarify the clinical significance of RIST with various graft sources, we retrospectively analyzed patients with AL or MDS who received RIST in our hospital.
Methods: The study included patients with acute myeloid leukemia (n=73), acute lymphoid leukemia (n=31) or MDS (n=25), who received fludarabine (Flu)/melphalan (Mel)-based RIST between 2004 and 2015 as the first transplantation.
Results: There were a total of 129 patients, including 3 in low risk (L), 74 in intermediate risk (I), 36 in high risk (H) and 16 in very high risk (V), classified by the refined disease risk index (rDRI). The median age was 58 years (range: 18-68 years), with 73 males and 56 females. Conditioning regimens contained Flu (125mg/m^2) combined with Mel (80mg/m^2, n=21 or 140mg/m^2, n=108). Total body irradiation (4Gy) was used in 96 patients who received transplantation from unrelated donors or HLA mismatched related donors. Bone marrow (BM) or peripheral blood stem cell (PB) from related donors was used in 40 patients, BM or PB from unrelated donors in 33 and cord blood (CB) from unrelated donors in 56. Primary graft failure occurred in 7 patients and death before engraftment was observed in two. After a median follow-up of 46 months (range: 15-144 months) for the survivors, the 1-year GRFS, disease free survival (DFS) and OS were 57%, 61% and 70%, respectively. On univariate analysis for all patients, pre-transplant factors associated with the 1-year GRFS included stem cell sources (BM/PB *vs* CB: 44% *vs* 68%, p=0.005), donors (related *vs* unrelated: 38% *vs* 62%, p=0.012), disease (AL *vs* MDS: 60% *vs* 28%, p<0.001) and rDRI (L/I *vs* H/V: 65% *vs* 38%, p=0.003). On multivariate analysis, BM/PB (HR 2.0, 95% CI 1.0-4.0, p=0.039), MDS (HR 2.6, 95% CI 1.5-4.6, p=0.001) and H/V rDRI (HR 2.1, 95% CI 1.2-3.5, p=0.006) were associated with a worse GRFS. The 5-year OS, cumulative incidence of relapse (CIR) and non-relapse mortality (NRM) were 55%, 36% and 18%, respectively. On univariate analysis, significant prognostic factors were hematopoietic cell transplantation-specific comorbidity index (HCT-CI) (score 0 vs >= 1: 78% *vs* 48%, p=0.007), disease (AL *vs* MDS: 59% *vs* 40%, p=0.004) and rDRI (L/I *vs* H/V: 64% *vs* 43%, p=0.003) for the 5-year OS, donors (related *vs* unrelated: 53% *vs* 27%, p=0.005) and rDRI (L/I *vs* HV: 27% *vs* 48%, p=0.005) for CIR, and age (<60 *vs* >= 60: 10% *vs* 28%, p=0.021), donors (related *vs* unrelated: 8% *vs* 23%, p=0.034) and disease (AL *vs* MDS: 13% *vs* 36%, p=0.003) for NRM. On multivariate analysis, HCT-CI score >= 1 (HR 3.1, 95% CI 1.3-7.4, p=0.009) and MDS (HR 2.4, 95% CI 1.3-4.5, p=0.005) were adversely associated with OS, so were H/V rDRI (HR 2.5, 95%CI 1.4-4.7, p=0.003) and MDS (HR 3.7, 95%CI 1.6-8.8, p=0.002) for CIR and NRM, respectively.

Summary/Conclusions: Our data suggest that Flu/Mel-based RIST was a promising strategy for patients with hematologic malignancy, irrespective of (?) donor or stem cell sources. However, GRFS and OS of MDS were significantly worse than those of AL, and MDS is strongly associated with high NRM even with RIST. This indicates that we should pay more attention to NRM in MDS.

PB2174

INCIDENCE AND RISK FACTORS FOR THE DEVELOPMENT OF HEMORRHAGIC CYSTITIS ON HAPLOIDENTICAL TRANSPLANTATION

M. Saez-Perdomo[1], M. Perera[1,*], J. Viedma[1], C. Rodriguez[1], A. Suarez[1], L. Guerra[1], J. Lopez[1], T. Molero[1], S. Jimenez[1]
[1]Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain

Background: Hemorrhagic cystitis (HC) is a serious complication ocurring after allogenic hematopoietic stem cell transplantation (HSCT) more frequent on haploidentical (haplo) HSCT, with an incidence of 10% to 70%(Silva et al Haematologica 2010;95(7):1183–1190) associated mainly with the effect of cytotoxic agents such as Cyclophosphamyde (Cy). The conditioning regimen, BKPyV infection and graft *versus* host disease have an implication in the incidence. Other authors related the reactivation of CMV and a previous transplantation as risk factors to HC development(Ruggeri et al Transplant Infectious Disease 2015:17:822–830).
Aims: With this study we aim to describe the HC incidence and risk factors in all haplo-HSCT performed in the Canary Islands.
Methods: We analyzed all consecutive haplo-HSCT from family donors performed at our Hospital between 2013 and 2016. The conditioning regimen used for the transplant was the Hopkins haplo protocol with high dose Cy (50 mg/kg on days 3 and 4) posttransplantation (PTCy). We used as HC prophylaxis intense hydratation on the Cy administration day and the following 24 hours (using bladder wash only in 1 patient with cardiac dysfunction) and perfused MESNA at 100% of Cy dose beginig 15 minutes before the Cy administration on 16 pts and at 20% of the last dose at 0, 4 and 8 hours on all pts. We used SPSS V.23 to determine the cumulative incidence (CI) of HC.
Results: We performed 20 haplo-HSCT, of which 10 were males (1 was transplanted 3 times) and 8 were women. The mean age was 40 (range 16-64). The pts presented the following diagnosis: AML (10), ALL (1), EH (5), NHL (3), AM (1). 45% of pts received the haplo-HSCT in remission, 50% with refractory disease and 5% of pts did not receive previous treatment. 6 pts developed HC (36.5% CI at day +80) (Figure 1a) with a median time from haplo-HSCT to onset of 23 days (range 3-42), 1 (17%) was grade I, 4 (66%) grade II and 1 (17%) grade IV. The grade I case did not received the MESNA infusion like most of the other pts. No pts died due to HC and all cases resolved without sequelae. 12 pts received Cy pre- and post-transplant and only 8 pts received PTCy. The CI at day +80 for the pts with PTCy was 33.3% and for Cy pre- and post-transplant 38.3% (Figure 1b). We found no statistically significant difference on the CI of HC between these two groups. The development of HC was related to Cy in 1 patient, who suffered from this complication on the second and third haplo-HSCT. For the rest of the pts (after day +30) the HC was related to BKPyV infection, as a consequence of the immunosuppression state of the patient, we also observed all these pts had positive serum viral load for CMV.

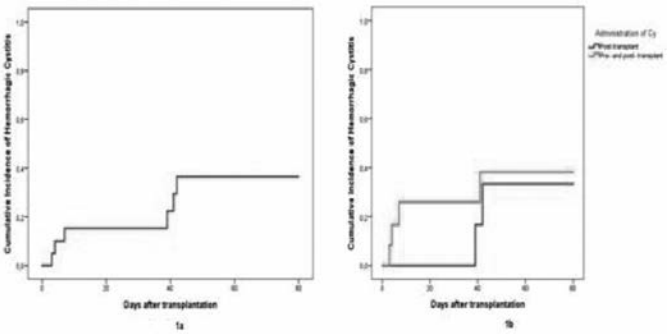

Figure 1.

Summary/Conclusions: The incidence of HC associated to post-HSCT high Cy dose in our series is 15% lower than other ones. Most of them on grade 1 or 2 and without mortality associated. The risk of HC is high, particularly in the setting of highly pre-treated patients (especially those undergoing a 2nd transplant). The development of HC after day +30 is evidently associated to BKPyV as a contributing factor for continuous inflammation and CMV reactivation (as an immunosuppression marker). In our study, HC did not have an impact on mortality of high-risk patients after haplo-HSCT. The HC remains frequent with a high morbidity in particular when it is severe, often causing prolonged hospitalization and resource use. We need further studies to recognize the at-risk population early.

PB2175

OUTCOME OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS UNDERGOING NON-MYELOABLATIVE ALLOGENIC STEM CELL TRANSPLANTATION AFTER TREATMENT WITH THE BRUTON TYROSINE KINASE INHIBITOR IBRUTINIB

F. Ramdohr[1,*], G.-N. Franke[1], M. Jentzsch[1], W. Pönisch[1], C. Michael[1], S. Heyn[1], S.-Y. Wang[1], G. Behre[1], S. Leiblein[1], S. Schwind[1], D. Niederwieser[1], V. Vucinic[1]
[1]Dept. Hematology & Clinical Oncology, University of Leipzig, Leipzig, Germany

Background: Although the Bruton tyrosine kinase (BTK) inhibitor ibrutinib significantly improves the prognosis of CLL patients (pts), allogeneic hematological stem cell transplantation (HCT) remains the only curative option for the underlying disease. Data on pre-transplant treatment of CLL with ibrutinib are very limited.
Aims: Here we present our experience of HCT in pts previously treated with ibrutinib.
Methods: 11 CLL pts (median age at HCT 57 years [y], range 52-66 y) treated between 2014 and 2016 in our unit with non-myeloablative (nma) HCT after ibrutinib were included. Ibrutinib treatment lasted median 4.03 months (range 1 - 28). Conditioning regimen was Fludarabin 30 mg/m^{2}on day -4 to -2 followed by 2 Gy total body irradiation. Disease status at HCT was Binet B (n=3) or Binet C (n=8). Two pts had Richter's transformation (RT) diagnosed before nma-HCT. Ten pts were in partial remission (PR) at nma-HCT (PR1 n=4; PR2 n=3; PR3 n=2, PR4 n=1) while one was in first relapse. Donors were human leukocyte antigen (HLA) matched related (n=3, MRD) or HLA-matched unrelated (n=8, MUD). Pts received median 3 lines of therapy (range 1-6) including ibrutinib before transplantation. Classical cytogenetic analysis and fluorescence *in situ* hybridization (FISH) was carried out for every pt. Five pts had a deletion (del)(17p13) and one a del(11q22.3).
Results: The average overall survival (OS) for all pts was 471 days (range 36-812) (Figure 1). The average OS of patients with del(17p13) was 379 days (range 66-628) compared to 456 days (range 36-812) for those without del(17p13, p=0.98). OS was not significantly influenced by the stem cell source (MUD *vs* MRD, p=0.63) or remission status PR1 *vs* >PR1 (353 *vs* 472 days, p=0.79). Non-matched CMV-Status (negative recipient and positive donor or positive recipient and negative donor) had an OS comparable to that of matched CMV-Status (p=0.73). Pts above the median age had a lower OS although this didn't reach significance (p=0.39). EFS was median 125 days (range 26-628). Pts with or without a TP53 alteration had a similar EFS (p=0.91). Pts undergoing MRD-HCT had better EFS than those undergoing MUD transplantation (p=0.055). CMV-Status or age>median had no prognostic influence on the EFS (p.0.83 and p=0.39 respectively). Non-relapse mortality (NRM) was 32% at 10 months (Figure 1), which was consistent with a previous publication from our group (30% at 4y). The acute GvHD Grade 3-4 was present in 3 pts (27.2%).

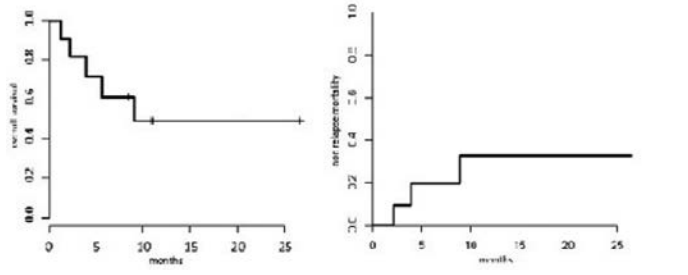

Figure 1.

Summary/Conclusions: The outcome in this small group is comparable to studies of CLL-pts undergoing nma-HCT without receiving ibrutinib upfront. Previous data from our unit (Hebenstreit *et al.*, Leuk Lymphoma 2014) showed OS 51% and NRM 30% at 4y. Ibrutinib appears to be a feasible option in a transplantation setting, although further testing with larger numbers of patients and a longer follow up is required.

SHORT-TERM CHIMERISM IN T-HELPER CELL SUBSETS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

D. Dubnyak[1,*], N. Risinskaya[2], M. Drokov[1], N. Kostritsa[3], L. Kuzmina[1], N. Popova[1], E. Mikhalcova[1], V. Vasilyeva[1], O. Koroleva[1], Z. Konova[1], I. Fevraleva[2], I. Galtseva[4], J. Davydova[4], N. Kapranov[4], A. Sudarikov[2], E. Parovichnikova[1], V. Savchenko[1]
[1]Bone marrow transplant department, [2]of Molecular Hematology, National Research Center for Hematology, [3]school of medicine, Lomonosov Moscow State University, [4]Laboratory of immunophenotyping, National Research Center for Hematology, Moscow, Russian Federation

Background: Despite the fact that almost all studies in transplant biology dedicate T-cells the chimerism in T-helper (Th) cells and its subsets such as T-regulatory (Treg) cells after allogeneic hematopoietic stem cell transplantation (allo-HSCT) has never been evaluated.
Aims: To evaluate Th, Treg and bone marrow cell short-term chimerism in allo-HSCT patients.
Methods: Between May 2015 and November 2016 there was 109 transplants in our center. The research included 24 patients with hematological malignancies (AML =14,ALL =7,MDS =2,CMML -1). The median age of patients was 33,5 (range 19 to 60) years old, female=16, male=8. Myeloablative conditioning regimen was used for 11 patients. The other 13 patients underwent reduced intensity conditioning regimen. Peripheral blood stem cells (PBSCs) as graft source was used in 9 patients, BM in 15 patients. 9 patients were transplanted from HLA-identical related donor ,15 - from unrelated matched. Chimerism was evaluated at +30, +60, and 90-day in blood and bone marrow. Peripheral blood mononuclear cells (PBMC) were isolated using standard protocol. Cells were sequentially incubated with CD4-biotin and anti-biotin microbeads (Milteney Biotec, Germany). Next pure fraction of Treg cells (CD4$^+$CD25^{high}) was obtained by positive selection with the use of anti-CD25 microbeads. DNA was isolated by AmpliSens DNA-sorbB nucleic acid extraction kit. Chimerism was assessed by the STR-PCR analysis (polymerase chain reaction with a panel of primers for loci of short tandem repeats).
Results: For detailed result see Figure 1. 18 patients didn't have any signs of relapse, graft failure or acute graft-*versus* host disease at all observation time. In this group on day 30% of cells with donors genotype was - 97,17±0,75; on day 60 – 95,75±2,15; on day 90- 98,21±0,80. On day 30 T-helper – 87,51±3,12; on day Th 60- 90,43±3,18; on day 90 Th – 93,71± 3,03. On day 30 T-regulatory – 77,36±4,50; on day 60Treg – 82,08± 5,94; on day 90Treg – 97,71± 1,18. Four patients were diagnosed with relapse at +4 and +6 months after allo-HSCT. Two patients were diagnosed with acute GVHD.

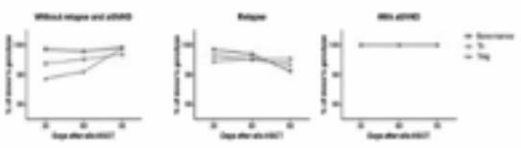

Figure 1.

Summary/Conclusions: Impact of chimerism in different T-helper subsets still need further investigation. We will continue our research and further results will be reported later.

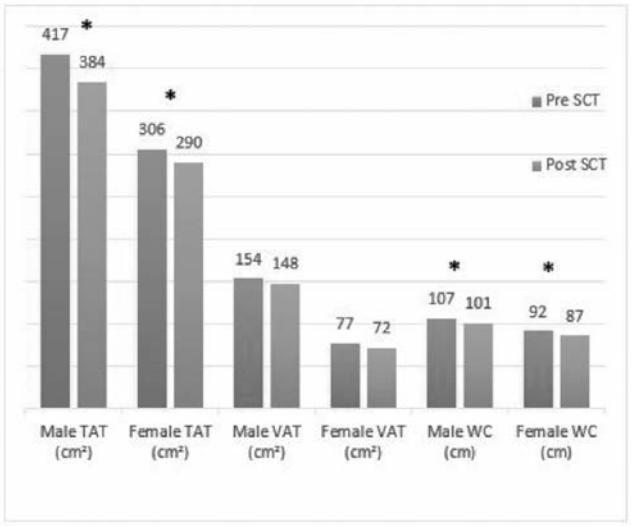
PB2177

ADIPOSE TISSUE CHANGES IN LYMPHOMA PATIENTS IN THE PERI TRANSPLANTATION PHASE

J. Jabbour[1,2], B. Manana[3], A. Zahreddine[4], C. Saadeh[5], C. Maya[3], A. Bazarbachi[4], D. Blaise[6], J. El Cheikh[3,*]
[1]Clinical Nutrition, American University of Beirut Medical Center, Beirut, Lebanon, [2]Ecole Doctorale Sciences de la vie et de la santé, Aix Marseille Université, Marseille, France, [3]Division of Hematology/Oncology, [4]Bone Marrow Transplantation Program, [5]Department of Radiology, American University of Beirut Medical Center, Beirut, Lebanon, American University of Beirut Medical Center, Beirut, Lebanon, [6]Programme de Transplantation et Thérapie Cellulaire, Centre de Recherche en Cancérologie de Marseille, Institut Paoli Calmettes, Marseille, France

Background: Abdominal Visceral Adipose Tissues (VAT) have been shown to have inflammatory activity and have been used to predict cancer outcomes. The ratio of VAT/Total Adipose Tissues (TAT) is a negative predictor of progression free survival in Lymphoma patients on chemotherapy.
Aims: Assess the changes in adipose tissues among stem cell lymphoma recipients in the peri-transplantation phase.
Methods: Institutional Review Board approved this retrospective study for adult patients (age>16 years) having B and T lymphoma who underwent Stem Cell Transplantation (SCT). Each patient was imaged by PET/CT scan pre-SCT and in the first 3 months post transplantation. A cross sectional image was analyzed at the level of the L3 to calculate TAT, VAT and Waist Circumference (WC). Data was analyzed by gender since body composition parameters differed significantly between the two categories in the literature.
Results: The study sample consisted of 91 patients [mean age: 37.7±13.5 years, n=52 (57%) males, n=81(87%) autologous SCT, n=12(13%) allogeneic SCT, median overall survival in months: 12 in males and 19 in females]. Death was observed in 6 (11.5%) males and 1(2.4%) female. Patient characteristics were similar across gender categories except for weights (kg) and Body Mass Index (kg/m^2): 88.1 and 28.6 *vs* 65.2 and 25.0, in males and females respectively (p<0.05). Changes from pre-SCT to 3 months post SCT revealed that TAT and VAT decreased with mean differences of 33±56 cm^2 (p<0.01) and 7.0±36 cm^2 (p=0.17) in males and 16±44 cm^2 (p<0.01) and 4±14 cm^2 (p=0.056) in females, respectively. Waist circumference decreased significantly with mean

differences of 3.9±4.9 cm and 2.8±4.4 cm in males and females, respectively (p<0.01). VAT/TAT withnissed a slight increase in males and reduction in females (p>0.05). In multivariate analysis, no significant associations were shown with mortality and progression rates (Figure 1).



* p value<0.05

Adipose Tissue Changes in the peri transplantation phase presented by gender.

TAT: Total Adipose Tissues; VAT: Visceral Adipose Tissues ; WC: Waist Circumference

Figure 1.

Summary/Conclusions: This study provides data on the evolution of adipose tissues parameters in the peri-transplantation phase. TAT, VAT and WC decrease 3 months post transplantation. Future studies should evaluate the associations of these parameters with major outcomes on larger sample sizes.

PB2178

NON RELAPSE MORTALITY (NRM) ANALYSIS IN 93 UNRELATED DONOR TRANSPLANTATION - SINGLE CENTRE EXPERIENCE - HLA HAPLOTYPE ROLE?

P. Mensah-Glanowska[1,2,*], B. Piątkowska-Jakubas[1,2], A. Radziszewska[2], A.B. Skotnicki[1,2]
[1]Department of Haematology, Krakow University Hospital, [2]Department of Haematology, Collegium Medicum Jagiellonian University, Krakow, Poland

Background: Unrelated donor stem cell transplantation has a curative potential against haematological malignancies. However there are concerns about associated risk of non-relapse mortality. We performed a retrospective single centre study of causes of non-relapse mortality over four year period - 2012-2016.
Aims: Purpose of the study was to analyse non-relapse mortality (NRM) in patients subjected to unrelated donor transplantation in four-year-period: 2012 to 2016 - 93 transplant procedures in 86 patients.
Methods: Study cohort was analysed - relapse rate and non-relapse mortality were assessed. Causes of both - early and late NRM were studied.
Results: There were 23 relapses in the group of assessed patient cohort (24,7%). 7 patients undergone the second transplant - five patients - because of AML relapse, later two - because of secondary graft failure. Out of re-transplanted 7 patients - 3 patients are alive - 2 patients with graft failure and one with post-transplant AML relapse in 2nd CR. Out of 93 procedures of unrelated donor transplantation there were 16 cases of death - assumed as non relapse mortality NRM (17%). There were 9 early deaths (before day +100) - 6 cases in patients with relapsed/refractory acute leukaemia without remission after conventional chemotherapy. These patients were subjected to sequential conditioning with cytreduction phase. Active disease and highly active antileukaemic treatment can be reason for higher treatment related toxicity and elevated risk of death. Later two patients developed infectious bacterial complications with septic shock. In one patient - antiviral treatment refractory CMV encephalitis with massive macrophage activation syndrome was diagnosed. Analysis of NRM after day100 revealed 7 affected patients. All these patients GVHD 2-4 was diagnosed previously, accompanied by transplant associated microangiopathy (TAM) and infections - both viral and fungal. Additionally to factors connected to NRM - age, comorbidity score, patient/donor HLA allelic and antigen and sex mismatches, HLA patient/donor haplotypes were analysed. It was possible to categorise 15 out of 16 NRM patients into 5 HLA class II haplotype groups connected with autoimmune diseases in Caucasian population - rheumatoid arthritis and lupus erythematosus: DRB1 01:01 DQB1 05:01 (5 patients), DRB1 03:01 DQB1 02:01 (4 patients), DRB1 11:01 DQB1 03:01 (3 patients), DRB1 15:01 DQB1 06:02 (2 patients), DRB1 04:01 DQB1 03:02 (1 patient).
Summary/Conclusions: Based on these results we create working hypothesis that HLA class II haplotype may predispose to severe post-transplant infectious or/and non-infectious complications and affect the risk of NRM. Because small number of analysed patients and documented high frequency of these haplotypes in population, further analysis is required.

PB2179

HAPLOIDENTICAL STEM CELL TRANSPLANTATION WITH HIGH DOSE CYCLOPHOSPHAMIDE POST-TRANSPLANT IN HIGH RISK HEMATOLOGIC MALIGNANCIES: RISK FACTOR AND OUTCOME ANALYSES IN OUR CENTER

J. Viedma[1,*], M. Saez-Perdomo[1], M. Perera[1], A. Suarez[1], J. Lopez[1], C. Medina[1], L. Guerra[1], M. T. Gómez-Casares[1], H. Luzardo[1], T. Molero[1], S. Jimenez[1]
[1]Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain

Background: Allogenic hematopoietic stem cell transplantation (allo-HSCT) is an effective therapy for a variety of hematological malignancies. However, a lack of HLA-identical sibling donors or unrelated donors has restricted the application of allo-HSCT in hematological malignancies. Haploidentical HSCT (Haplo-HSCT) offers the benefits of rapid and nearly universal donor availability and, in the past decade, has been accepted worldwide as an alternative treatment for patients with hematological malignancies who do not have an HLA-identical sibling donor or who require urgent transplantation.
Aims: The purpose of this study was to investigate the incidence, causes and factors influencing overall and transplant-related mortality after Haplo-HSCT.
Methods: We analyzed all consecutive patients receiving Haplo-HSCT from family donors at our hospital from 2013 to 2016. The conditioning regimen used for the transplant was the Hopkins haplo protocol with high dose Cy (50 mg/kg on days 3 and 4) posttransplantation. We classified the patients before the Haplo-HSCT according to disease risk index (DRI), ECOG, Sorror score and EBMT risk score to evaluate the correlation between the physical state of the patients before the transplant and the survival (overall mortality (OM) and transplant-related mortality (TRM)). We used SPSS V.23 to calculate the cumulative Mortality incidence by the KM test and the Cox proportional hazards model.

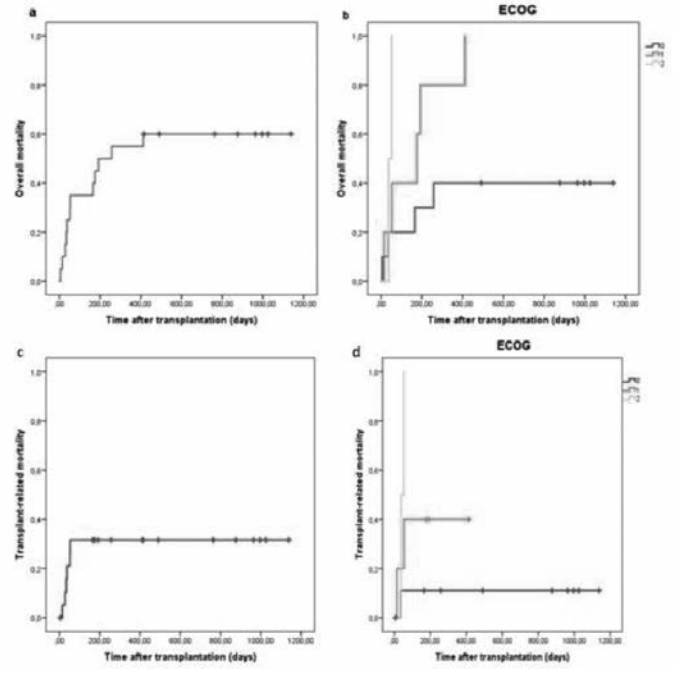


Figure 1.

Results: We performed 20 haplo-HSCT, 10 were males (1 was transplanted 3 times) and 8 were females mean age of 40 (range 16-64). Diagnosis: AML (10), ALL (1), EH (5), NHL (3), AM (1). Forty five percent of patients received the haplo-HSCT in remission, 50% with refractory disease and 5% of patients did not receive previous treatment. Of the 20 patients from our series, 12 died post transplant with an OM of 60%. The cumulative incidence (CI) of OM was 15% at 1 month (m), 35% at 3 m, 45% at 6 m, 55% at 1 year, and 40% at 2 and 3 years (Figure 1a). When we analyzed the OM depending on the different physical status scores we found no statistically significant differ-

ence between OM from the different states of EBMT (p=0.356) and DRI (p=0.07), however we found a statistically significant difference for ECOG (p=0.028) (Figure 1b) and Sorror (p=0.016). On a pairwise analysis of the OM we found no statistically signification for EBMT, and found a statistically significant difference between the patients with low-high DRI (p=0.01), intermediate-high DRI (p=0.01), ECOG 0-1 (p=0.046) and Sorror 0-5 (p=0.003). The multivariate analysis showed that ECOG 2 *vs* 0 (p=0.013, HR=46.59), Sorror 2-3 *vs* 0-1 (p=0.041, HR=19.55) and Sorror 4-5 *vs* 0-1 (p=0.005, HR=282.48) were significantly related with a higher incidence of OM. Five patients died of infection (41.67%), 3 of disease progression (25%), 1 of relapse (8.33%) and 3 of other causes (25%). Six patients died of TRM (50%). The CI of TRM was 10.5% at 1 m and 31.6% at 3 m, 6 m, 1, 2 and 3 years (Figure 1c). When we analyzed the TRM depending on the different physical status scores we only found a statistically significant difference between TRM incidence from the different states of ECOG (p=0.038) (Figure 1d) and no statistically significant difference for EBMT (p=0.386), DRI (p=0.372) and Sorror (p=0.073). On the pairwise analysis we also found statistically significant differences between ECOG 1-2 (p=0.018) and EBMT 1-5 (p=0.046), for Sorror we found a marginal statistical signification between 0-1 (p=0.052), 0-2 (p=0.052) and 0-5 (p=0.052), for DRI we found no statistically significant difference. On the multivariate analysis we found no statistically significant correlation between TRM and the physical status scores.

Summary/Conclusions: Despite the fact that Sorror, EBMT and DRI scores are widely validated to establish the risk of patients undergoing HSCT, in our experience ECOG remains a useful score for assessing the risk of TRM on patients receiving Haplo-HSCT. We think further studies with a larger sample would be necessary to confirm our results.

PB2180

A SIMPLIFIED METHOD OF CRYOPRESERVATION OF PERIPHERAL BLOOD STEM CELLS WITH OVER 10% GRANULOCYTE CONCENTRATION FOR LESS THAN 36MONTHS

T. Akagi[1,*], K. Ota[2], T. Fujii[2], K. Kamata[3], K. Mayama[3], K. Yamaguchi[3], K. Yamagata[3], S. Fukuda[3], K. KUbo[2]
[1]Transfusion and Cell Therapy, [2]Hematology, Aomori prefectural central hospital, Aomori, [3]Gastroenterology and Hematology, Hirosaki University Hospital, HIrosaki, Japan

Background: The long-term stability of cryopreserved peripheral blood stem cells (PBSCs) is an important concern for patients experiencing disease relapse. However, the quality of long-term cryopreserved PBSCs stored at -80°C by using simplified method has not been elucidated in detail. Cryopreserved PBSCs undergo cell damage and decrease in viability, and those containing granulocytes might influence cell loss.
Aims: The aim of this study was to evaluate the effect of cryopreservation for less than 36 months and the number of granulocytes in the cryopreserved PBSC products on $CD34^+$ cells.
Methods: We examined the effects of cryopreservation on the viability of CD34+ cells that were stored for less than six months and those stored for 7–24 months, and 25-36 months, and the change of CD34+ cell viability with higher granulocyte content. We also evaluated the correlations between the number of granulocyte in the cryopreserved PBSC products and the time to engraftment of leukocyte or platelet. Informed consent was obtained prior to the procedure from all the patients following institutional guidelines.
Results: A total of 65 PBSC samples were collected. We compared three groups based on the cryopreservation period: (1) less than 6 months, (2) 7–24 months, and (3) 25-36 months. The median (range) viability of CD34+ cells after thawing was 81.8% (58.2–94.4). 80.5% (56.6–92.8), and 76.1% (54.5–89.6) in the three groups, respectively. No significant difference in the viability of the cells in either frozen period was observed (p=0.14, respectively). We compared the effect of granulocyte concentration (over 10% concentration against less than 10% concentration) on CD34+ cells viability. The median (range) viability of CD34+ cells containing >10% granulocytes was 76.6% (54.5–93.0%), and that for cells containing <10% granulocyte was 82.1% (59.1–94.4%), respectively. There was significant difference in the viability of CD34+ cells between the two groups (p=0.02, respectively). Second, we analyzed 81 autologous PBSC transplants after stored at -80°C by using simplified method. We compared two groups based on the granulocyte concentration (>10% concentration against <10% concentration). No significant difference in the days to leukocyte >1.0x10^9/L and to platelet >20x10^9/L in either granulocyte concentration was observed. However, the median (range) time to platelet >50x10^9/L containing >10% granulocytes was 27.2(12-87), and that for cells containing <10% granulocyte was 20.3(10-51), respectively. There was significant difference in the day to platelet >50x10^9/L between the two groups (p=0.04, respectively).
Summary/Conclusions: Long-term cryopreservation represents a means of holding a potential therapeutic modality in reserve for use at a future date. In this study, PBSCs can safely be stored for at least36 months by the simplified method at -80°C. The loss of the viability of CD34+ cells was greater when the granulocyte content was over 10% than in cells with less than 10% of granulocytes. The effect of reduced CD34+ cells viability seems important for engraftment. Difference in the day to platelet >50x10^9/L between the two groups based on the granulocyte concentration (>10% concentration against <10% concentration) was observed. Thus, a lesser granulocyte content could give a more reliable graft with better quality. Further research is necessary to observe the effect of long-term cryopreservation period and granulocyte content on the viability of stored CD34+ cells.

PB2181

LYMPHOCYTE RECONSTITUTION AFTER ALOGENIC TRANSPLANTATION, DOES EARLY RECOVERY HAVE ANY INFLUENCE IN SURVIVAL RATES?

V. Verdugo[1,*], M.A. Correa Alonso[1], V. Rubio Sanchez[1]
[1]Hematology, Hospital Jerez de la Frontera, El Puerto de Santa María, Spain

Background: Immune reconstitution after AloTPH has significant influence on the procedure final success. Studies have established that early lymphocyte recovery can influence survival rates, associated to a reduction in mortality unrelated relapse (NMR) and, in some studies, also to a reduction in relapse rate.
Aims: Analyze our patients survival rates in terms of lymphocyte reconstitution in absolute value on day+30 and+60 post-HSCT. Check if there is any relationship between the number of transfused CD34+ progenitors and LT3+ and see if that possible link affects the speed of recovery after transplant t- lymphocyte count.
Methods: Analysis of the lymphoid recovery in a retrospective study of 63 of 71 patients transplanted (ALO, and Haplo Unrelated Donor) by AML and ALL between 2008- 2015. (8 died before the day+60). Table 1 shows the characteristics of the pre-transplanted patients and analyze the influence of the parameters of the infused product (CD34x10^6 and LTx10^8/kg r), type of transplant, GVHD presentation. treatment and reactivation of CMV on the recovery of absolute lymphocyte numbers in s+30 and +60 days post transplantation using as cutt off <0.3x10^3/ml. We have analyzed the ratio of the number of lymphocytes on day +60 with survival after transplantation. It has made a statistical - analysis of OS and DFS in relation to the number of lymphocytes on day +30 and day +60 with Kaplan Meier compared the results with long-rank test and subsequent analysis of the variables collected with Cox Regression.
Results: After analyzing the product infused we observe a relationship between LT and lymphocyte recovery on day+30 (p: 0097, cor: 0223) and day +60 (p=0.059, cor: 0257) but not with the CD34+/Kg r. Table 2 shows the patient characteristics in lymphocyte absolute count in the day +60. We analyzed the overall survival (OS) and disease - free survival (DFS) and a decrease in OS with statistical difference was evident in patients with <.300 (p=0.0029) on day +60 and day+30 (p: 0.05), a decline also in DFS, with no statistically significant difference (p=0.1). Multivariate analysis to determine which factors could influence the lymphoid recovery on day +60 and SG, we observed that the type of unrelated donor, myeloablative conditioning and ATG administration can influence a delay in this recovery. No differences were observed in the rest of the variables.

Table 1.

CHARACTERISTICS OF THE PATIENT S:

SEX:	
- Male: 44 (62%)	
- Female: 27 (38%)	
AGE: Median: 41 (14-69)	
DIAGNOSTICS:	
- LLA: 22 (31%)	
- LMA: 47 (66.2%)	
- THE Biphenotype: 1 (1.4%)	
- Bilinear: 1 (1.4%)	
STATE OF ILLNESS TO TRANSPLANTATION:	
- RC: 55 (77.4%)	
- RP / EMR + 10 (14%)	
- Refractoriness: 6 (8.45%)	
STEM CELL:	
- SP: 66 (92.95%)	
- MO: 2 (2.8%)	
- SCU: 3 (4.2%)	
DONOR:	
- DE: 48 (67.6%)	
- DNE: 20 (28.165)	
- Haploidentical: 3 (4.2%)	
CONDITIONING:	
- MIELOBLATIVO: 46 (64.8%)	
- Low Intensity: 25 (35.2%)	

Summary/Conclusions: A delay in lymphocyte recovery is associated with a decrease in survival rates in our patients. Measures favoring an accelerated lymphocyte recovery (judicious use of thymoglobulin, adequate donor selection, and transplantation modality) could affect the post-transplant survival. It appears that the amount of infused product could play an important role in reconstitution, so it would be a factor to take into account prior to infusion.

PB2182

SUCCESFULL AUTOLOGOUS STEM CELL TRANSPLANTATION AFTER VELCADE-BASED REFRACTORY MULTIPLE MYELOMA PATIENTS

V. Martínez-Robles[1,*], B. Ballina[1], S. Cerdá[1], N. de las Heras[1], J.A. Rodríguez-García[1], F. Escalante[1]
[1]Hematología, Complejo Asistencial Universitario de León, LEON, Spain

Background: The optimal induction treatment for Newly Diagnosed Multiple Myeloma Patients needs combinations with Bortezomib-Based (Bor-Based) schemes. Primary Refractory patients include patients with progressive disease or rapid (<60 d) relapse after these optimal induction approach have a very bad prognosis. Lenalidomide-Dexamethasone (LenDex) were usually the next step in the treament of these patients, until the recent introduction of triplets combination LenDex-based. Autologous Stem Cell Transplantation (ASCT) have proven efficacy in NDMM younger patients that have got at least a partial response (PR) after the induction therapy. There are few data about toxicity and response of ASCT in primary refractory patient that can obtain a response with LenDex rescue treatment.
Aims: Analysis of tolerance, response and overall survival of ASCT-candidates that are primary refractory to Bor-Based induction treatment.
Methods: Retrospective analysis of our database. From 2010 to Nov-2016, 53 ASCT-Candidates (for 1st or 2nd ASCT procedures) were included. Median Age for diagnosis was 62 (46-71). Median Age for ASCT procedure was 63 (46-72). 12 of these 53 patients (22.6%) were considered primary refractory and considered candidates to get Len-Based rescue treatment. 6 of them (50%) were woman. Characteristics of Disease: IgG kappa (4), IgG-lambda (3), IgA kappa (3), IgA lambda (1), Light Chain lambda (1). ISS I/II/III): 5/2/5. Induction treatment: VelDex (4), VTD (6), VCD (2). Median of cycles administered: 6 (2-8). Best Response to induction treatment: >PR (6), Minimal Response (1), progressive disease (5) Len-Based (12). Plus CFM in 3 of them to optimize response. Median number of cycles administered: 6 (3-12). 3 of them didn´t responde. Of the other 9, 6 of them were considered candidate to intensificate treatment with high doses chemotherapy supported with an ASCT (2 of 6 to a 2nd ASCT procedure). The other 3 patients are in treatment or in preASCT evaluation. Characteristics of the after-rescue ASCT-patients. Median age at ASCT: 62 (49-70). All of them received Melphalan 200 mg/m2 as conditioning treatment.
Results: Morbidity or mortality (M&M) (0%) of ASCT procedure in refractory patients is similar to non-refractory patients. After a median follow up of 46 months from diagnosis for all ASCT-candidates group, the refractory patients get an overall survival of 46.2 months (3-72 m). Any of them have relapsed yet. 2 of them are in biological relapse without need of treatment.
Summary/Conclusions: Patients refractoriness to induction may receive ASCT after a rescue treatment LenDex based, as is effective in this group conventionally considered to have a very bad outcome. New combinations (triplet) with new drugs with LenDex-based treatment may improve the responses rates and overall survival before and after of ASCT procedure in these group.

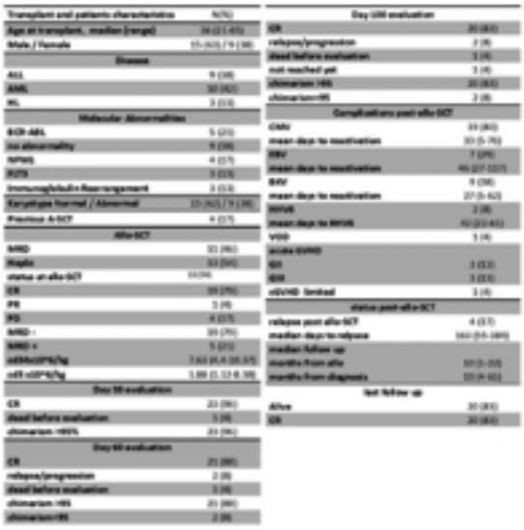
PB2183

SAFETY AND EFFICACY OF TBF CONDITIONING IN PATIENTS UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION.A RETROSPECTIVE SINGLE CENTER EXPERIENCE.

R. Massoud[1,*], N. Moukalled[1], B. Haffar[1], A. Zahreddine[1], A. Bazarbachi[1], J. El-Cheikh[1]
[1]Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon

Background: The optimal intensity of myeloablation with a reduced-toxicity conditioning (RTC) regimen to decrease relapse rate after allogeneic stem cell transplant (allo-SCT)without increasing non-relapse mortality (NRM), has not been well established.
Aims: In this retrospective study at the American University of Beirut medical center (AUBMC) we aimed to evaluate the outcomes of patients who underwent allo-SCT with thiotepa, busulfan and fludarabine (TBF) as RTC.
Methods: We included twenty fourconsecutivepatients with hematological malignancies who received TBF as conditioning forallo-SCTfrom January to December 2016**.** All patients and transplant characteristics are listed in Table1. All patients received the myeloablative conditioning regimen consisting ofthiotepa(5mg/kg/day)infused on day -7 and -6, fludarabine(30mg/m^2/day) was infused on day -5 to day -2; and busulfan(130mg/m^2/day) was infused on day -5 to day-3. All patients received 2.5mg/kg/day intravenousrabbit antithymocyte globulin (ATG) on days -2 and -1. GVHD prophylaxis for patients transplanted from haploidentical donors consisted of post-transplant cyclophosphamide 50mg/kg/day on day +3 and day +5, cyclosporine started at 3 mg/kg/day on day+6 and readjusted according to level, and mycophenolate mofetil 500mgx4/day started on day+6 to +28. Patients transplanted from matched related donor, received cyclosporine as of day +1.
Results: Twenty three patients(96%) engrafted, with 14 days (range, 10-18) and 13 days (range, 8-48) as median time for neutrophil and platelet engraftment respectively. One patient who underwent haploidentical donor transplant with persistent disease for AML (karyotype 45,XY,-7) failed to engraft and died due to disease progression on day+22.After a median follow up of 10 months (range, 1-22) post-allo-SCT, the cumulative incidence of GradeII-IV acute GVHD (aGVHD) was 26%. One patient developed chronic limited GVHD (cGVHD).All the complication post allo-SCT are listed in table 1. Five patients (24%) relapsed post allo-SCT at a median of 163 days (range, 55-384), of which three (13%) died due to disease progression, and two were successfully salvaged and are in complete remission (CR) with full donor chimerism (FDC) at last follow up. Two patients developed JC virus progressive multifocal leukoencephalopathy, one of them made a full recovery and the other died in CR. The day 100 NRM was 0%. At last follow up 20 patients (83%) are alive in CR, with negative minimal residual disease and FDC.

Table 1.



Summary/Conclusions: Our results show that This TBF conditioning regimen appears to be safe,allows high rate of engraftment and low NRM rate among high-risk patients and can lead to a long-term disease control.

PB2184

COMPLETE REMISSION STATUS BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION AS PROGNOSTIC FACTOR IN PATIENTS WITH NON-HODGKIN LYMPHOMA

A. Pinto[1,*], A. Roque[1,2], M. Gomes[1], E. Cortesão,[12], A. Espadana[1], A.B. Sarmento[1,2], C. Geraldes[1,2], M.L. Ribeiro[1]
[1]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, [2]Faculty of Medicine and CIMAGO, University of Coimbra, Coimbra, Portugal

Background: High dose chemotherapy (HDC) followed by autologous stem cell transplantation (ASCT) is commonly used for treatment of relapsed or refractory non-Hodgkin's lymphoma (NHL), as well as for first-remission consolidation in patients with mantle cell lymphoma. Disease status before ASCT is variable and is unclear whether complete response before ASCT or after ASCT correlates with better survival.
Aims: To evaluate the prognostic effect of disease status before ASCT - complete remission (CR) *vs* partial remission (PR) - in a cohort of patients with NHL.
Methods: Retrospective analysis of patients with NHL treated with HDT and ASCT between 2007 and 2016 in a single institution. All patients received peripheral blood stem cell support after conditioning with BEAM regimen (carmustine 300mg/m^2, etoposide 800mg/m^2, Ara-c 1600mg/m^{2}and melphalan140 mg/m^2). Response was assessed according to The Lugano Classification. The Kaplan-Meier method was used to estimate progression free survival (PFS) and overall survival (OS) and comparison between risk groups was performed by using the log-rank test. Univariate analysis was performed and significant predictors at the level of 0.05 were used to adjust a multivariate Cox regression model.
Results: We included 83 NHL patients, mainly males (72.3%) with a median age at diagnosis of 51 years (18-65). The most prevalent histological subtypes were diffuse large B cell lymphoma (53.0%), mantle cell lymphoma (36.1%) and follicular lymphoma (15.7%). The median number of therapeutic lines was 2 (1-5). Patients with diffuse large B cell lymphoma and follicular lymphoma were mainly treated with R-CHOP/R-CVP (82.5%) at first-line. For those who did not achieve a CR or relapsed after first-line treatment, (R)-ESHAP/DHAP/ICE (78.8%) was performed as second-line followed by ASCT as salvage therapy in order to achieve and consolidate CR. The majority of patients with mantle cell lymphoma received R-CHOP/R-DHAP (55.0%) followed by consolidation with ASCT in first remission. With a median follow-up time from ASCT of 39.66 months (0.3-117.6), OS at 2 and 5 years was 84.8%

and 74.5% and PFS was 76.8% and 58.2%, respectively. Before ASCT, 60 patients (72.3%) were in CR and 23 (27.7%) were in PR. After ACST, 4 patients were not assessed for response due to early death by toxicity. Of the remaining, 70 (88.6%) achieved a CR, 4 (5.1%) a PR and 5 (6.3%) failed to respond. Patients in CR before ASCT presented significantly longer PFS compared with those in PR (107.9 *vs* 44.0 months, p=0.01). Besides that, patients that obtained CR after ASCT also had longer OS and PFS compared with those in PR (107.9 *vs* 8.0 and 107.9 *vs* 7.3 months, p<0.001). However, these patients had significantly lower PFS compared to patients that continued in CR after ASCT (45.3 *vs* 107.9 months, p=0.041). Univariate analysis indicated that remission status pre-ASCT (CR *vs* PR) is a significant predictor of PFS after ASCT (HR 0.39; 95% CI 0.19-0.82, p=0.013). Multivariate Cox regression model showed that this factor retains prognostic value after adjustment for age, histological subtype, Ann Arbor stage and number of previous lines of treatment.

Summary/Conclusions: Our results highlight the relevance of the obtained CR after ASCT in the OS. Furthermore, we conclude that patients with NHL who are in CR before ASCT have a better PFS than those in PR before ASCT. Additionally, continued CR after ASCT may also be an important prognostic factor. Our results suggest that the use of more effective induction regimens in order to improve initial response may be advantageous in terms of clinical benefits post-ASCT.

PB2185

AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MANTLE CELL LYMPHOMA:SINGLE CENTER EXPERIENCE

S.K. Toprak[1,*], E. Atilla[1], P. Ataca Atilla[1], S. Civriz Bozdag[1], M. Kurt Yuksel[1], P. Topcuoglu[1], T. Demirer[1], O. Arslan[1], M. Ozcan[1], M. Arat[2], O. Ilhan[1], H. Akan[1], M. Beksac[1], N. Konuk[1], A. Uysal[3], G. Gurman[1]
[1]Ankara University School of Medicine Department of Hematology, Ankara, [2]Florence Nightingale Hospital, Istanbul, [3]Koru Hospital, Ankara, Turkey

Background: Mantle cell lymphoma accounts for relatively small proportion (3%>10%) of non-Hodgkin lymphoma. High-dose chemotherapy (HDT) and autologous-stem cell transplantation (ASCT) has played a critical role in the treatment of mantle cell lymphoma. Regardless of that, mantle cell lymphoma remains largely a relapsing/remitting disease.

Aims: Our aim is to present our mantle cell lymphoma patients who underwent ASCT.

Methods: We retrospectively evaluated our 21 mantle cell NHL patients. The patients were followed after ASCT for relapse

Results: Patients were followed by a median time of 56.9 months (range, 6-170 months).The median age at diagnosis was 45 (range, 18-69), female to male ratio:5/16. The stages and MIPI scores at diagnosis were as follows: 5% stage II, 19% stage III, 76% stage IV; Low MIPI 29%, intermediate MIPI 48% and high MIPI 23%. First line treatments were R-CHOP for 6 cycles in 6 patients (29%) and R-CHOP for 3 cycles followed by R-DHAP in 15 patients (71%). The median time to ASCT was 20 months (range, 7-48 months). All patients were in at least partial remission at the time of ASCT. The transplant conditioning regimen was CVB in 5 patients (24%) and R+/-ICE in 5 patients (24%), R+/-BEAM in 11 patients (52%). Six patients (29%) achieved complete remission. Four patients (19%) died within three months of ASCT due to infection. Eleven patients (52%) was relapsed with a median time of 39 months (range, 4-123 months). Ten patients received BORID (bortezomib, rituximab, dexamethasone) and 1 patient received lenalidomide as salvage therapy and six of them achieved complete remission. Three patients underwent allogeneic hematopoietic stem cell transplantation as well as two patients received ibrutinib as fourth line therapy and followed in remission. The 3 year overall survival was 71%.

Summary/Conclusions: ASCT is a part of initial treatment strategy in fit patients with mantle cell lymphoma however%19 patients in our series had transplant related toxicity. Today, novel agents may present a less intensive approach for achieving response.

PB2186

ALLOGENEIC STEM CELL TRANSPLANTATION IN CHILDREN WITH AUTISM

A. Gomes[1,*], A. B. Mafra[1], A. Zanette[1], V. Rocha[1]
[1]Hematopoietic Stem Cell Transplantation, Hospital Sirio Libanês, Sao Paulo, Brazil

Background: Autism Spectrum Disorders (ASD) are severe heterogeneous neurodevelopmental abnormalities characterized by dysfunctions in social interactions and communication skills, restricted interests, repetitive, and stereotypic verbal and non-verbal behaviors. The etiology of ASD remains unknown, but recent studies suggest a possible association with altered immune responses and ASD. Inflammation in the brain and Central Nervous System has been reported with microglia activation and increased cytokine production in post-mortem brain specimens of individuals with ASD. Other studies have established a correlation between ASD and family history of autoimmune diseases, associations with MHC complex haplotypes, and abnormal levels of various inflammatory cytokines and immunological markers in the blood. The paracrine, secretome, and immunomodulatory effects of stem cells would appear to be the likely mechanisms of application for ASD therapeutics.

Aims: Evaluation the benefits of HSCT in patients with ASD.

Methods: We describe two cases of patients with ASD who underwent HSCT for acute lymphoblastic leukemia (ALL) and whose symptoms were markedly decreased like an improvement of social interaction, communication, and behaviors.

Results: The first patient is an 11-year-old girl with ASD who was diagnosis with Ph-positive ALL in October 2011 (at the end of treatment, BCR-ABL remained positive). She underwent a matched sibling HSCT in March 2015. The conditioning regimen was total body irradiation (TBI) and cyclophosphamide. During the 20-month follow-up period, we observed improvement in social interaction, communication, and behaviours. According to The Childhood Autism Rating Scale – CARS, prior to HSCT, she had a score of 39 (Severe Symptoms of ASDisorder), and she currently scores 30 (Mild-to-Moderate Symptoms of ASD). The second case is a 7-year-old boy with ASD, Asperger Syndrome, who was diagnosis with ALL in September 2012. He presented with bone marrow and testicular relapse in May 2015 and underwent a matched unrelated HSCT in November 2015. The conditioning regimen was Etoposide, ATG and TBI. During the 12-month follow-up period, we observed improvement in social interaction, communication, and behaviours. According to CARS, prior to HSCT he had a score of 30 (Mild-to-Moderate Symptoms of ASD), and he currently scores 24 (Minimal-to-No Symptoms of ASD). There is no treatment for ASD thus every effort to minimize the symptoms are valuable. In both cases, social interaction was significantly increased, and the aggressive behaviors decreased. Clinical cases have reported responses in autistic children receiving cord blood CD34+ cells.

Summary/Conclusions: Several incurable neurological disorders have shown benefits with cellular therapy. Thus, autism should be explored as an indication. Clinical studies are an immediate need to fully explore its potential in autism.

PB2187

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PEDIATRIC MYELODYSPLASTIC SYNDROMES: A SINGLE CENTER EXPERIENCE FROM TURKEY

D. Atay[1,*], F. Erbey[1], A. Akcay[1], G. Ozturk[1]
[1]Pediatric Hematology Oncology Bone Marrow Transplantation Unit, Acibadem University Medicine Faculty, Istanbul, Turkey

Background: Myelodysplastic syndrome (MDS) in childhood is a rare disorder and hematopoietic stem cell transplantation (HSCT) is the only known curative treatment option. However, there exist few reports regarding the outcome of transplantation for children with various types of MDS.

Aims: We analyzed the outcome of pediatric patients who underwent HSCT in our center.

Methods: We reviewed retrospectively 14 pediatric MDS patients who received HSCT at a single center. Median age at time of HSCT of the patients was 4.3 years and disease duration from diagnosis to transplantation ranged from 3 to 36 months with a median of 10 months. Five patients had primary and one had secondary MDS. Four patients had juvenile myelomonocytic leukemia (JMML) and 4 patients had myelodysplastic related acute myeloid leukemia (MDR-AML). Diagnostic cytogenetics included monosomy 7 (n=2), trisomy 8 (n=3), KRAS (n=1) or normal/other (n=8). Patients received a median of $6.8x10^6$ CD34+cells/kg. Eight patients received a bone marrow, 5 had peripheral blood graft and one an unrelated cord blood (UCB) transplant; five patients were transplanted from a matched sibling donor (MSD), 5 from a matched unrelated donor (MUD) and 4 from haploidentical donor. Conditioning regimen consisted of busulfan/cyclophosphamide in MSD/MUD patients. The patients transplanted from MUD and UCB also received antithymocyte globulin (ATG) for 3–5 days pretransplantation. Haploidentical transplantation was performed with RIC regimen and TCRαβ /CD3 depletion.

Results: Graft failure occurred in three patients with JMML (n=1), secondary MDS (n=1) and MDR-AML (n=1). Except one, all of the JMML patients relapsed at a median 83.5 days post-transplant and two of them died. One patient with MDR-AML underwent second transplantation from another MUD one year after first transplant and died from GVHD. Ten patients are alive with a median follow-up of 19.5 months (range 3-61). All patients with primer MDS are alive and well. Four patients died from transplant-related toxicity (n=2) and relapse (n=2). For the entire group, estimated five-year relapse-free survival (RFS), event-free survival (EFS) and overall survival (OS) were 78.6%, 64.3% and 70.7%, respectively.

Summary/Conclusions: These data demonstrate that especially children with primer MDS may achieve encouraging OS and RFS following HSCT. Relapse remains the main cause of treatment failure in children with JMML given HSCT. All children with MDS should be referred for allogeneic HSCT soon after diagnosis.

Thalassemias

RELATIONSHIP BETWEEN URIC ACID LEVELS AND CARDIAC FINDINGS IN A LARGE COHORT OF B-THALASSEMIA MAJOR: GENDER-RELATED DIFFERENCES

A. Meloni[1,*], C. Vassalle[1], L. Pistoia[1], T. Grippo[2], M. G. Bisconte[3], G. Palazzi[4], M. P. Smacchia[5], N. Dello Iacono[6], R. Ndreu[1], A. Olivi[1], V. Positano[1], A. Pepe[1]
[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Azienda Ospedaliera Regionale San Carlo di Potenza, Potenza, [3]Azienda Ospedaliera Cosenza - Presidio Ospedaliero "Annunziata", Cosenza, [4]Modena, Policlinico di Modena, [5]Policlinico Umberto 1, Roma, [6]Ospedale Casa Sollievo della Sofferenza IRCCS, San Giovanni Rotondo, Italy

Background: Iron overload, secondary to recurrent transfusions and ineffective erythropoiesis, induces oxidative stress in thalassemia (TM). Uric acid (UA), a major blood antioxidant, may act either as an antioxidant or pro-oxidant.
Aims: Our aim was to evaluate the role of UA in TM and its association with cardiac iron, dysfunction, fibrosis, and complications, and cardiovascular risk factors in a large cohort of TM patients of both sexes.
Methods: 397 TM patients (200 men, mean age 32±8 years) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network were considered. Myocardial and hepatic iron burdens were quantified by the T2* technique. Atrial dimensions and biventricular function were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.
Results: As expected, UA resulted significantly higher in male respect to female TM patients (4.74.7±1.3 *vs* 4.0±1.0 mg/dL; P<0.0001).
UA levels directly correlated with BMI (R=0.25, P=0.0003), and triglycerides (TG) (R=0.20, P=0.005) in female patients. Moreover, female which presented myocardial fibrosis showed higher levels of UA (4.4±1.3 *vs* 3.9±0.9 mg/dL, P=0.03). The multiple regression model identified BMI (T-value 3.7, P=0.0003), TG (2.1, P=0.04) and cardiac fibrosis (2.5, P=0.01) as independent correlates of UA level in women. In men, UA levels were positively correlated with BMI (R=0.17, P=0.02), TG (R=0.38, P<0.001), and inversely with HDL (R=-0.20, P=0.006) and glycemia (R=-0.15, P=0.04). Interestingly, UA was also directly correlated with global heart T2* values (R=0.3, P<0.001). After multivariate analysis adjustment, global heart T2* (T-value 2.6, P=0.01), TG (4.7, P<0.001), and BMI (1.9, P=0.05) remained as independent determinants of UA in male TM patients.
Summary/Conclusions: UA levels correlates with factors related to metabolic dysfunction in TM patients of both sex, while a more strong correlation between UA and cardiac fibrosis was observed only in females, and a direct relationship between UA and T2* global heart only in males. The differences in male and female TM patients imply some gender-specific mechanisms, providing biochemical basis for the epidemiological differences between sexes.

PB2189

CHARACTERIZATION OF HEMORHEOLOGICAL ALTERATIONS IN THALASSEMIA BY A CHEMOMETRIC APPROACH

P. Caprari[1,*], C. Bozzi[1], S. Materazzi[2], R. Risoluti[2]
[1]Haematology, Oncology and Molecular Medicine, Istituto Superiore di Sanità, [2]Department of Chemistry, "Sapienza" - University of Rome, Rome, Italy

Background: Several studies reported a high incidence of thromboembolic events in β - thalassemia, more frequent in thalassemia intermedia than in regularly transfused thalassemia major. In these patients a chronic hypercoagulable state is evident and the red blood cells exhibit impaired flow properties that facilitate micro-circulatory disorders.
Aims: Since many abnormalities described in thalassemia may determine rheological alterations, in this study we have investigated the viscoelastic profiles of red blood cells from patients with β-thalassemia. The hemorheological profiles of blood samples obtained from healthy subjects and thalassemic patients were studied by chemometric tools in order to develop a model of prediction of circulatory disorders according to the viscoelastic behaviour.
Methods: Blood samples from 45 β-thalassemia patients and 48 healthy individuals, after informed consent, were analyzed. Hemorheologic profiles were investigated at 37 °C at native and normalized hematocrit. The evaluation of RBCs viscoelastic properties was performed by determining storage modulus G', loss modulus G" and complex modulus G* in oscillation mode as a function of angular frequency ω in the range 0.1-10 Hz. Multivariate statistical analysis was performed on the resulting G', G'' and G* curves and Principal Components Analysis was used as display method.
Results: The hemorheological profiles of patients affected by ß-thalassemia and healthy subjects showed significant differences and the chemometric analysis demonstrated a clearly identification of anemic status according to viscoelastic profile. Increased G', G'' and G* modula were observed in thalassemic patients demonstrating a reduction in deformability and impaired flow properties.
Summary/Conclusions: In this study a characterization of haemorheological alterations in thalassemia patients has been performed by a chemometric approach. The achieved results permit to consider the viscoelastic properties as promising predictive new indices of microvascular damage in β-thalassemia and to explain the increased incidence of vascular complications in these disorders.

PB2190

HEPATITIS E IN TRANSFUSION-DEPENDENT THALASSEMIA PATIENTS, IN GREECE. A SINGLE CENTER EXPERIENCE

P. Klonizakis[1,*], G. Gioula[1], A. Melidou[1], M. Exindari[1], G. Karavalakis[2], C. Apostolou[1], E. Gigi[1], E. Vetsiou[1], A. Kotsiafti[1], E. Vlachaki[1]
[1]Aristotle University of Thessaloniki, [2]Papanikolaou General Hospital, Thessaloniki, Greece

Background: Hepatitis E (HE) is nowadays considered an emerging disease that may be a threat in both developing and industrialized countries all over the world. The causal agent is an RNA virus, transmitted mainly through the fecal-oral route. Nevertheless, there are additional patterns of transmission, including the transfusion of infected blood products. The risk of developing chronic HE infection following transfusion of infected blood–derived products is higher among immune-compromised individuals. Transfusion-dependent Thalassemia patients consist a distinct category of immune-compromised patients, but the data regarding transfusion-transmitted HE infection are limited for this group of patients. Accordingly, there is, as yet, no consensus on whether blood products should be systematically screened for markers of the HE virus
Aims: The aim of this study was to assess the status of Hepatitis E infection in 96 transfusion-dependent Thalassemia patients, followed up in a single Thalassemia Unit, in Northern Greece.
Methods: Over a one-month period, we retrospectively evaluated 96 consecutive patients, from a registry of 150 adult TDT patients followed at a single Thalassemia Unit, in Northern Greece. The mean age of the study population was 36±10 years, 42% were male and 58% female. According to the patients' blood transfusion history, the participants had been transfused with 47.376 blood units during the last 14 years, whereas during the last year the same patient population had been transfused with 3.384 blood units. The detection of HEV RNA was performed by Real-Time RT-PCR method (hepatitise2@ceeramTools kit, Applied Biosystems ABI), according to the instructions. The detection of HEV was based on the identification of the "a" region of ORF2. The detection of IgG anti-HEV antibodies and their titration were performed in 92/96 samples using a commercially available enzyme-linked immunosorbent assay kit (CUSABIO BIOTECH kit), according to the manufacturer's instructions. The cut-off value was calculated according to the manufacturer's instructions.
Results: HE RNA was not detected in any of the 96 samples, whereas the IgG anti-HEV antibodies were also negative in all measured samples. The negative HEV RNA, in all the participants of this study, indicates the absence of an active HE infection, whereas the negative IgG anti-HEV antibody titre implicates that there was no history of previous HE infection. According to the literature, IgG antibodies may be detectable following an HE infection for a time period that varies from one year to 14 years.
Summary/Conclusions: This is the first assessment of the HE virus seroprevalence in the population of TDT patients in Greece, over the last two decades. Our results suggest that TDT patients are not at a high risk for HE infection. Further studies are necessary to evaluate the clinical importance of the transfusion-transmitted HE infection in TDT patients and clarify whether screening of blood donors is necessary for countries with a lower or higher prevalence of HE.

PB2192

A PRELIMINARY STUDY OF THE CARDIAC EFFECT OF PPAR GAMMA IN BETA THALASSEMIA MAJOR WITH IRON OVERLOAD

P.M. Eldefrawy[1,*], P.N.A. Hamed[1], D.D. Elnileey[2], D.O. Ghallab[1], M.A. Khalifa[1]
[1]Hematology, [2]Clinical Pathology, Alexandria Faculty of Medicine, Alexandria, Egypt

Background: Peroxisome proliferator–activated receptor (PPAR)-gamma is a transcription factor belonging to the same family of nuclear receptors as steroid and thyroid hormone receptors. PPAR-gamma is a master transcriptional regulator involved in the expression of probably hundreds of genes. One of PPAR gamma gene polymorphisms is Pro12Ala which is present in at least 80% of humans. Pro12Ala polymorphism may reduce the risk of cardiovascular complications. Consistently, Ala12 allele carriers were found to have lower carotid intima- media thickness and reduced risk of myocardial infarction in type 2 diabetes patients. Pharmacological agonists of PPAR-gamma leads to a molecular

switch providing alleviating myocardial injury through modulating oxidative, inflammatory and apoptotic signaling pathway.
Aims: Our aim was to investigate the frequency of Pro12Ala polymorphism (substitution of proline to alanine at codon 12 in exon B of PPARγ gene in Egyptian β-thalassemia major (β-TM) with iron overload. Untreated transfusion induced iron overload in thalassemia major is fatal, usually as a result of cardiac complications.
Methods: 30 β-TM patients and 10 healthy volunteer matched for age, sex and body weight were involved in this study. β-TM patients followed up was in the "outpatient clinic of Hematology unit, at Alexandria main university hospital". Seventeen were males and thirteen were females with ages ranging from 16 – 39 years (21.53±5.44). Blood samples from β-TM patients and healthy controls were analyzed for PPARγ gene polymorphism using polymerase chain reaction-restriction fragment length polymorphism.
Results: The mean value of serum ferritin in β-TM was 4976.30±2216.41 ng/L which was significantly higher than that in controls (102.60±12.69 ng/L). The mean value of ejection fraction were 62.23±3.46% and 63.80±4.34 in cases and controls respectively. Pro12Ala polymorphism was present in 2 out of 30 (6.67%) β-TM patients with osteoporosis. One patient had heterozygous 12Ala polymorphism and the other had homozygous 12Ala polymorphism. Both had normal body mass index, lipid profile, ejection fraction and elevated serum ferritin (4923 ng/l in heterozygous patient and 4886 ng/l in homozygous patient). Ejection fraction was 70% in heterozygous patient and 68% in homozygous patient. Only one male control (10%) has homozygous 12Ala polymorphism (Table 1).

Table 1.

Comparison between the two studied groups according to PPAR gamma genotyping

Parameter	Cases (n = 30)		Control (n = 10)		χ^2	MCp
	No.	%	No.	%		
Genotyping						
Normal	28	93.3	9	90.0		
Heterozygous	1	3.3	0	0.0	1.509	0.585
Homozygous	1	3.3	1	10.0		

Data of the two cases with PPAR gamma polymorphism

Parameter	Homozygous	Heterozygous
Age (years)	20	18
Sex	male	Female
Body mass index	19.83	20.20
Ferritin (ng/ml)	4886	4923
FBG (mg/dl) kg/m^2	79	87
Triglyceride (mg/dl)	128	97
Total cholesterol (mg/dl)	130	161
HDL (mg/dl)	8	25
LDL (mg/dl)	80	71
Ejection fraction (%)	68	70
BMD	-6	-2.4

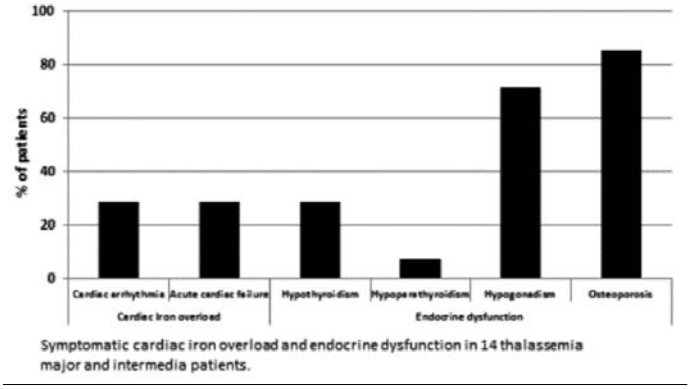
Summary/Conclusions: This study suggests that Pro12Ala polymorphism may have a cardioprotective effect in Egyptian thalassemic patients since we find the highest value of ejection fraction among the two positive cases. Further studies on a larger population of patients are still needed to confirm this finding.

PB2193

THALASSEMIA MAJOR AND INTERMEDIA IN PATIENTS OLDER THAN THIRTY-FIVE YEARS - FROM A FATAL TO A CHRONIC DISEASE

O. Pasvolsky[1,*], L. Shargian Alon[1], P. Raanani[1]
[1]Beilinson Hospital, Petach Tikva, Israel

Background: During the past four decades beta thalassemia major (TM) and beta thalassemia intermedia (TI) have transformed from a universally fatal disease at a young age, into a chronic disease, with a constantly increasing life expectancy. This is attributed, amongst others, to the use of improved chelation therapy. Since prolongation of life expectancy has occurred only in recent years, there is little data regarding the older population with TM and TI.
Aims: We aimed to characterize disease and patients' characteristics in patients above 35 years of age in an adult thalassemia center in Israel.
Methods: We conducted a retrospective analysis of 14 adult patients over the age of 35 years with TM (N=10) and TI (N=4) treated in a single center, specializing in the care of adult thalassemia patients. We used descriptive statistics to describe characteristics of disease and patients and the Mann-Whiteny test to compare between patients with TI and patients with TM.
Results: Between 2006 and 2016, 14 adult patients older than 35 years with TM (n=10) & TI (n=4) were followed and treated in our center. Median patients' age was 37 (range, 35-51) years, with 66% males and 50% of Arab ethnicity. Most of the patients had at least high school education (85%), and 78% were employed. Thirteen patients (all TM patients and 3 out of the 4 TI patients) were treated regularly with blood transfusions. All patients received chelation treatment. Median hemoglobin (Hb) levels and mean corpuscular volume (MCV) levels were lower in patients with TI compared to TM (8.1 *vs* 10 g/dl, p=.002 and 72.4 *vs* 84 fl, p=.004, respectively). Median LDH levels and indirect bilirubin levels were higher in patients with TI compared to TM (603 *vs* 330 u/L, p=.004 and 2.02 *vs* 1.1 mg/dl, p=.06, respectively) indicating increased hemolysis. All patients underwent splenectomy and had secondary thrombocytosis. All but two patients were treated with at least two different chelation modalities, either as single agent, including subcutaneous (SC) or intravenous (IV) deferioxamine (DFO), deferiprone (DFP), or deferasirox (DFX), or as various combination therapy options. The median number of chelation treatment lines was 3. All patients treated with chelation suffered from at least one adverse event, necessitating temporary discontinuation and usually substitution of treatment. The median number of adverse events was 1.5 per patient. Nine patients (64.2%) had good compliance with current chelation therapy. Four patients with acute heart failure secondary to cardiac iron overload, and all four improved with intensified chelation treatment. Four TM patients (40%) were hypothyroid, half of them requiring thyroid hormone replacement therapy. All TM patients had hypogonadism. All females had amenorrhea and were treated with hormone replacement therapy, and none of them tried to conceive. Six of the seven male TM patients were treated with monthly testosterone injections, and three of them fathered children. All TM patients had osteoporosis, and three TI patients (75%) had metabolic bone disease. Figure 1 shows the relative rates of symptomatic cardiac iron overload and endocrine dysfunction in the cohort. Three patients (21.4%) had significant liver overload according to liver T2* MRI, necessitating chelation treatment intensification. None of the patients in our cohort underwent allogeneic hematopoietic stem cell transplantation and none developed secondary malignancy during follow-up.



Symptomatic cardiac iron overload and endocrine dysfunction in 14 thalassemia major and intermedia patients.

Figure 1.

Summary/Conclusions: Advances in the treatment of thalassemia patients have enabled the majority of these patients prolonged survival into adulthood. However, this has brought a new set of challenges for both patients and healthcare. This study delineates the challenges faced while treating adult patients with TI and TM in the new era.

PB2194

EVALUATION OF LIVER IRON CONCENTRATIONS IN CHILDREN WITH BETA THALASSEMIA INFECTED WITH HEPATITIS C VIRUS BEFORE AND AFTER SPIRULINA THERAPY BY MAGNETIC RESONANCE IMAGING

M. El-Shanshory[1,*], M. Awad[1], R. El-Shafey[2], A. Alsharkawy[3]
[1]Pediatrics, [2]Radiology, Faculty of Medicine, Tanta University, [3]Pediatrics, Ministry of Health, Tanta, Egypt

Background: Magnetic resonance imaging (MRI) assessment of liver iron concentration (LIC) is necessary for quantitative staging of iron overload in children with β-Thalassemia. There is no enough evidence about the effect of spirulina therapy on LIC.
Aims: To assess LIC by MRI in multitransfused β-Thalassemic children infected with HCV before and after Spirulina Therapy.
Methods: Thirty multi-transfused β-thalassemic children infected with HCV, were subjected to clinical evaluation, appropriate laboratory investigations and assessment of LIC by MRI. They were classified according to LIC into mild

(group 1) and moderate to severe group (group 2). In addition to standard packed red cell transfusion, Spirulina therapy was given orally for 3 months, after which re-evaluation of these children was performed by repeating the same investigations.
Results: There was significant increase in LIC associated with significant changes in other MRI parameters (significant decrease in T2* and significant increase in R2*) in patients with β-Thalassemia of moderate to severe group as compared to those of the mild group before treatment. The mean values of serum ferritin (SF) was statistically insignificantly higher among patients of mild group. There was no significant correlation between different MRI parameters and SF level. There was negative correlations between LIC and T2* and positive correlation between LIC and R2*. There was significant decrease in values of LIC accompanied with significant improvements in SF after spirulina therapy as compared to their pretreatment values in patients of the moderate to severe group.

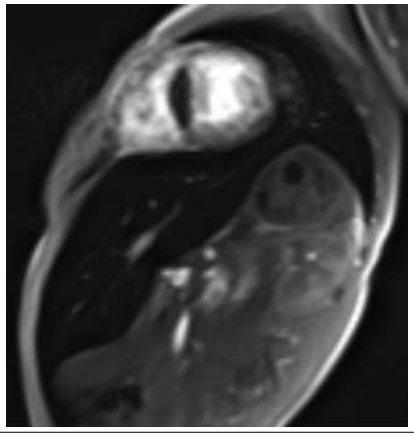


Figure 1.

Summary/Conclusions: Spirulina therapy may have favorable effects on lowering the values of LIC in children with β-Thalassemia infected with HCV.

PB2195

COMBINATION OF DEFERASIROX AND DEFEROXAMINE - A SUCCESSFUL CHELATION THERAPY IN B-THALASSEMIA MAJOR PATIENTS

F. Petropoulou[1,*], K. Ventiadi[1], G. Leveta[1]
[1]Thalassaemia Unit, General Hospital of Athens "G.Gennimatas", Athens, Greece

Background: Frequent transfusions required for β- thalassemia major patients cause iron overload. Without the appropriate chelation therapy, iron toxicity can cause significant heart, liver and endocrine morbidity.
Aims: In this case series we estimated the safety and efficacy of iron chelation with the combination of deferasirox (DFX) and deferoxamine (DFO) in transfusion dependent thalassemia (TDT) patients attending the Thalassemia Unit in a tertiary hospital in Athens, Greece.
Methods: 10 TDT patients were treated with a combination chelation therapy of DFX (30 ±10mg/kg/d) and DFO (44±12mg/kg/d for 2-6 days/wk in 12hr or 24hr infusion rates). Reasons for starting this combination treatment included: 1) treatment with one chelating agent did not succeed in decreasing heart and liver iron, 2) agranulocytosis or severe neutropenia due to deferiprone (DFP) treatment and 3) adverse events recorded with increased doses of one of the chelating agents. The efficacy of the treatment was estimated through MRI measurements of heart and liver iron ($T2^*_{Heart}$, and LIC) in combination with serum ferritin levels. Liver enzymes (ALT, AST) and serum creatinine were used to monitor safety of the treatment.
Results: Five of the 10 patients had significant liver hemosiderosis (LIC >15 mg Fe/gr d.w.) and 3 had heart iron overload, of which one significant (T2* 1.9 msec) (Table 1).

Table 1.

	Before starting DFX/DFO combination therapy	**12mos into** the DFX/DFO combination therapy
Serum Ferritin mean	3,360 ng/mL (range 1,700- 6,200)	2,450 ng/mL (range 800-4,900)
Liver Iron Concentration (LIC) mean	19.0 mg Fe/gr d.w. (range 6.2-46.4)	9 mg Fe/gr d.w. (range 1.6- 28.4)
Cardiac T2* mean	24.1 msec (range 1.9-36)	32.3 msec (range 5.2 -39.5)

The combination treatment was well tolerated without adverse events or effects on liver and kidney function.
Summary/Conclusions: The combination chelation with DFX/DFO can decrease iron overload and represents a safe and effective option when monotherapy is not effective or not well tolerated.

PB2196

EVALUATION OF THREE AUTOMATIC DEVICES FOR HEMOGLOBINOPATHY DIAGNOSTICS IN MULTI-ETHNIC POPULATIONS

C. Harteveld[1,*], Y. Daniel[2], G. Bakker-Verweij[1], G. Ivaldi[3]
[1]Clinical Genetics, Leiden University Medical Centre, Leiden, Netherlands, [2]Special Haematology, Guy's Hospital, London, United Kingdom, [3]Laboratorio di Genetica Umana, Ospedale Galliera, Genoa, Italy

Background: We have tested three different dedicated haemoglobin separation devices for their capacity of performing the diagnostics of hemoglobinopathies. These involve the Variant II ™ HPLC (BioRad), the Capillarys2 capillary electrophoresis (Sebia) and the most recently introduced HPLC, Premier Hb9210™ High Resolution HPLC of Trinity Biotech (Menarini).
Aims: As the latter device is new to the market a multisite precision study was performed testing the reproducibility of the system across three test sites (Leiden, Genoa and London) using the same set of samples for several following days. The results between these three sites were compared and evaluated. Moreover we have tested the capacity to detect the most common structural haemoglobin variants, such as HbS, HbC, HbD, HbE and less common Hb variants important to be diagnosed in multi-ethnic populations found in the U.K., The Netherlands and Northern Italy as well as elevated HbA_2 , as indicator for beta-thalassemia carriers.
Methods: tHb variant separation using he Variant II ™ HPLC (BioRad), the Capillarys2 capillary electrophoresis (Sebia) and the most recently introduced HPLC, Premier Hb9210™ High Resolution HPLC of Trinity Biotech (Menarini). Molecular analysis to verify the hemoglobin variants found.
Results: We present the data of the comparison studies using the replicates of the three different sites for the Premier Hb9210™ and of 100 normal samples and 217 patient samples for a variety of beta-thalassemia trait and haemoglobin (Hb) variants, including the molecular data of the beta-thalassemia mutations and Hb variants.
Summary/Conclusions: All three apparatuses identified the common Hb variants and beta-thalassemia trait in carriers, homo- , hetero- and compound heterozygotes with the expected sensitivity and specificity. The Premier Hb9210™ High Resolution HPLC of Trinity Biotech shows comparible separation and quantitation on the three different sites using the same samples and is suitable for the analysis of samples suspected of having hemoglobinopathy and the diagnosis of beta-thalassemia trait or Hb variants.

PB2197

RED BLOOD CELL EXTENDED PARAMETERS IN HAEMOGLOBINOPATHIES

M. Stamou[1], E. Petridou[1], A. Kotanidou[1], A. Agorasti[1,*]
[1]Laboratory Haematology, General Hospital of Xanthi, Xanthi, Greece

Background: Sysmex® XE-5000 analyzer incorporates new research Red Blood Cell (RBC) parameters, derived from flow fluorescence cytometry technology, including%HYPO-H*e*, which indicates the percentage of RBC with haemoglobin (Hb) content <17 pg, and%MicroR which indicates the percentage of RBC with mean cell volume <60 fL.
Aims: The aim of this study was to establish the reference range of our Laboratory for the parameters%HYPO-H*e* &%MicroR, to investigate their values in haemoglobinopathies and their correlation, if any, with Hb A_2 levels in heterozygous β-thalassaemia.
Methods: Reference ranges were obtained from 175 healthy adult subjects (27 men, median age of 34 years & 148 women, median age of 30 years); control group (group A). 89 haemoglobinopathie heterozygotes (32 men, median age of 29 years & 57 women, median age of 30 years) were included in the study and classified into three groups; group B: β-thalassaemia heterozygotes, N=46, group C: α-thalassaemia heterozygotes, N=21 and group D: Hb O-Arab heterozygotes, N=22. We retrospectively recorded the results of full blood count analysis on Sysmex® XE-5000 analyzer including%HYPO-H*e* &%MicroR, of Hb pattern analysis (TOSOH®, G7) and ferritin levels (Roche®, cobas *e*411). All subjects included in the study presented ferritin levels within the normal range for age and gender. Statistical analysis: one-way ANOVA (Tukey post-hoc), Mann-Whitney, Pearson's correlation tests were applied. Reference ranges were calculated as the mean±2SD of the distribution. P value <0.05 was considered to be statistically significant. Data refer as median (percentiles).
Results: The reference ranges of our Laboratory for the parameters%HYPO-H*e* &%MicroR are 0.0 – 0.6% & 0.2 – 2.9%, respectively, and they are independent of gender and age (P=0.715, P=0.168 & P=0.073, P=0.843). There was a statistically significant difference between the groups as determined by one-way ANOVA for both parameters (all P <0.0001). Heterozygous β-thalassaemia presents statistically significantly higher%HYPO-H*e* values [11.6 (4.2-27.6)] as compared to groups A [0.3 (0.2-0.3)], C [1.9 (0.6-4.6)], D [0.6 (0.4-0.8)] (all P <0.0001), while there was no statistically significant difference of%HYPO-H*e* values between heterozygous Hb O-Arab and groups A and C (P=0.965 & P=0.134, respectively) based on Tukey post hoc test. Heterozygous β-thalassaemia presents statistically significantly higher%MicroR values [41.5 (22.9-58.7)] as compared to groups A [1.5 (1.1-2.0)], C [10.8 (7.9-20.5)] and D

[6.1 (4.2-9.0)] (all P <0.0001). Both parameters%HYPO-H*e* &%MicroR are correlated positively in a statistically significant degree with Hb A_2 levels in heterozygous β-thalassaemia (r=0.567, P <0.0001, y=0.050x+5.317 & r=0.680, P <0.0001, y=0.042x+4.371, respectively).
Summary/Conclusions: β-thalassaemia heterozygotes present higher values of%HYPO-H*e* &%MicroR compared to α-thalassaemia and Hb O-Arab heterozygotes.%HYPO-H*e* &%MicroR are possibly useful parameters for evaluating the relative severity of different genotypes in heterozygous β-thalassaemia because of the statistically significant positive correlation with Hb A_2 levels.

PB2198

PERFORMANCE OF THE ALPHA-GLOBIN STRIPASSAY® AND MLPA® FOR THE DIAGNOSIS OF ALPHA-THALASSAEMIA
J. Oosterbos[1], H. Claerhout[2,*], C. L. Harteveld[3], E. Lierman[4], D. Kieffer[2,5]
[1]Department of Pharmaceutical and Pharmacological Sciences, KU Leuven, [2]Department of Laboratory Medicine, University Hospitals Leuven, Leuven, [3]Department of Clinical Genetics, Leiden University Medical Center, Leiden, [4]Center for Human genetics, University Hospitals Leuven, [5]Department of Microbiology and Immunology, KU Leuven, Leuven, Belgium

Background: Diagnosing α-thalassaemia requires second line diagnostics involving DNA analysis. Multiplex ligation probe amplification® (MLPA®) is a molecular technique introduced as a diagnostic tool for α-thalassaemia. This semi-quantitative technique determines the relative copy number of up to 60 DNA sequences and is able to detect deletions and duplications in a DNA sample. A novel commercial tool, the α-Globin StripAssay®, aims to detect the most common α-thalassaemia deletions and point mutations. The test involves three steps: DNA isolation, PCR reaction and a hybridization step to test strip containing allele-specific oligonucleotide probes immobilised as an array of parallel lines.
Aims: Our objective was to evaluate the α-Globin StripAssay® as a useful alternative for MLPA® in second line α-thalassaemia diagnostics.
Methods: Eight samples, including 7 known deletions (_ _SEA, _ _THAI, _ _MED, homozygous and heterozygous - $\alpha^{3.7}$, heterozygous - $\alpha^{4.2}$, $(\alpha)^{20.5}$) and 1 mutation (Hb Constant Spring) were analysed using multiplex Gap-PCR (deletions) and Sanger sequencing (point mutation) at the Leiden University Medical Center. These samples were anonymised and analysed in duplicate by MLPA® and α-Globin StripAssay® at our center. A comparison of diagnostic performance, interpretation, turnaround time (TAT) and costs (reagent and labour) was done.
Results: There are no significant differences between the MLPA® and the α-Globin StripAssay® results and each identification corresponded to the result of the reference lab in Leiden. MLPA® however provided additional information about underlying polymorphisms. Interpretation of the α-Globin StripAssay® was easier and faster compared to MLPA®. The α-Globin StripAssay® proved to have a shorter TAT, but on the other hand, the costs for MLPA® were significantly less.
Summary/Conclusions: Despite its straightforward interpretation, shorter TAT and the ability of detecting both (known) deletions and point mutations, the significantly higher costs of the α-Globin StripAssay® may hinder it's routine use. Specialised laboratories are usually acquainted with the MLPA technique and in these settings the ability to detect both known and unknown deletions is a plus for research purposes.

PB2199

CARDIAC AND HEPATIC IRON ASSESSMENT OF YOUNG ADULTS WITH TRANSFUSION DEPENDENT THALASSEMIA: TIME TO THINK BEYOND FERRITIN
K. Mishra[1,*], S. Kashyap[1], A. Khadwal[1], A. Jandial[2], D. Lad[1], G. Prakash[1], R. Das[3], N. Varma[3], P. Malhotra[1], S. Varma[1]
[1]internal medicine , [2]Pgimer, Chandigarh, Chandigarh, India, [3]haematology, Pgimer, Chandigarh, Chandigarh, India

Background: With the improvement in availability of blood transfusion practices and progress in chelation therapy, there is an increasing population of thalassemic patients surviving into adulthood in developing countries. However, there is scarcity of clinical, biochemical and radiological data showing cardiac and hepatic iron assessment in these chronically transfused individuals.
Aims: 1. Cardiac and hepatic iron assessment in young adults with TDT. 2. Compare the ferritin level with T2* MRI finding.
Methods: in this prospective observational study we analysed demographic details, clinical features and cardiac and liver iron assessment of young adults with (TDT) at recently established adult thalassemia clinic at PGIMER, Chandigarh. For cardiac and liver iron assessment serum ferritin, ECG, 2D Echo, MUGA scan, Liver function test, Fibroscan (if indicated) and T2* MRI of Liver and heart was done. All patients who were diagnosed in childhood and referred to adult haematology unit at age ≥18 years and had received more than 20 blood transfusions were included in the study.
Results: A total of 53 patients (n=53) were analysed. The mean age was 23 yrs. Majority of patients (56%) were male. The average age at diagnosis and at first transfusion was 7 months & 11months respectively. The average years of PRBC transfusion was 23 yrs. The average number of transfusion in last two years prior to registration was 24 PRBC units. The mean age at start of chelation was 10.0 yrs. Mean duration of chelation was 14 yrs. Majority (88%) had growth failure with mean height of 159.6 cm & mean weight of 51.5 kg respectively. Splenomegaly was present in 47% and hepatomegaly in 25%patients. Twenty-eight percent have undergone splenectomy at an average age of 12.6 yrs. The mean of highest ferritin levels was 6131 ng/mL and the mean ferritin at the time of registration was 2919 ng/mL. LFT were deranged in 25% of patients. Evidence of cardiac dysfunction (ECG/MUGA) was present in 22% of patients. Iron overload in liver and heart as measured with T2* MRI was present in 56% & 28% respectively (Figure 1).

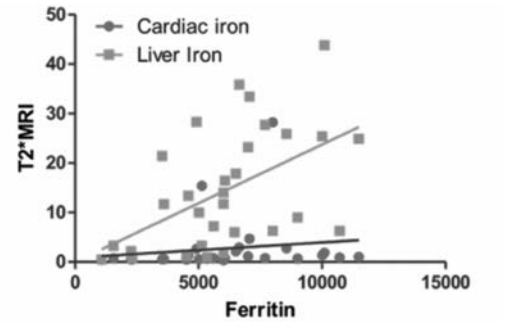

Figure 1.

Summary/Conclusions: majority of patients registered in our clinic are living a healthy life. All of them were on iron chelation therapy and the dose was being adjusted as per the serum ferritin level. Amongst asymptomatic individuals with no evidence of cardiac or hepatic dysfunction, evaluation by T2*MRI picked up evidence of hepatic and cardiac iron overload. Therefore, its prudent to monitor patients with T2*MRI and accordingly escalate or de-escalate chelation therapy.

THALASSEMIA IN MADRID: A PICTURE OF THE CURRENT SITUATION
E.J. Bardón-Cancho[1,*], M. García-Morín[1], Y. Aguilar-de la Red[1], B. Ponce-Salas[1], G. Perez-Rus[2], C. Pascual[2], E. Dulín[3], C. Beléndez[1], E. Cela[1]
[1]Section of Pediatric Hematology and Oncology, Department of Pediatrics, [2]Department of Hematology, [3]Newborn Screening Laboratory (Community of Madrid), Hospital General Universitario Gregorio Marañón - Facultad de Medicina- Universidad Complutense de Madrid, Madrid, Spain

Background: Diagnosis of thalassemia (Thal) in a Mediterranean country as Spain, could be thought as endemic, but few data are available so far. Moreover, attention to hemoglobinopathies is focused on sickle cell disease.
Aims: The aim of our study was to find out the prevalence of Thal and clinical significant hemoglobinopathies other than sickle cell diseases in a referral center for newborn sickle screening, in addition to the demographic characteristics of these patients. The secondary objectives were to obtain the frequency of specific treatments or prophylaxis accomplished by these patients, and the reasons for loss to follow-up.
Methods: The study is observational, unicentric, descriptive and retrospective, carried out in December 2016 in a tertiary hospital in the Community of Madrid, Spain. All patients diagnosed with Thal and other not sickle-hemoglobinopathies who had attended at least once to the hematology clinic were included. Demographic characteristics (date of birth, gender, country of birth) and clinical ones (genotype or Thal type, therapy and update in follow up, like alive, deceased or lost patient) were collected. Written informed consent was signed by patients or legal guardians in accordance with the Declaration of Helsinki. The study was approved by the hospital Ethical Committee. Statistical analyses were performed using SPSS version 18.0. Quantitative variables were reported as median or mean value and range, while categorical variables were expressed as absolute value and percentage.
Results: The total number of patients included was 31 (9 Thalassemia Major (TM), 1 Thalassemia Intermedia (TI), 21 other not sickle-hemoglobinopathies). The center follows 209 sickle patients, which leads to a ratio sickle/not sickle of 6.74 (Table 1). Ratio boy/girl is 1.21 for all group. Most of patients were born in Spain (90.32%), although 6.45% were born in Asia and one patient was born in Rumania. Considering the parents, 32% were born in Europe, 29% from Africa, 25% from Asia, and 12% from America. 92% of those patients born in Spain were detected in their first days of life due to universal screening detection implemented in Madrid since 2003. Median age at first diagnosis was 0.70 years (0-16.35). Median age at the end of inclusion was 9.39 years (range 1.90 to 35.44). 35% of them had molecular genotyping for diagnostic confirmation. Two out of 10 patients with Thal had HLA identical siblings. Quelation treatment was added to standard treatment to all the patients with Thal: 7 received deferasirox, 3 were treated with deferoxamine and 2 with deferiprone; 2 of the patients required double quelation. Two out of 10 patients with Thal underwent

splenectomy. None of these patients had sepsis or meningitis. Three Thal patients underwent progenitor stem cell transplantations and they remain on complete chimerism in the present moment. Patients lost to follow-up summed up 14: 3 emigrated to other countries, 2 continue the monitor of their diseases in other centers or in adults units and 7 for unknown reasons. There was one death (3.22%) for a cause unrelated to his illness.

Table 1.

Hemoglobinopathies	n (%)
Heterozygote β-Thal + Another variant of Hb (C, D, Andrew-Minneapolis, J Baltimore)	6 (28.57)
Hb CC	4 (19.04)
Hb EE	2 (9.52)
Heterozygote Hb O-Arab	2 (9.52)
Hb OO	1 (4.76)

Hb H	1 (4.76)
Hb DE	1 (4.76)
Hb CE	1 (4.76)
Hb OC	1 (4.76)

Not sickle-hemoglobinopathies

Summary/Conclusions: Early diagnosis derived from universal neonatal screening for sickle cell disease allows an effective health education and prompt therapy to other hemoglobinopathies, and a correct and thorough follow-up of these patients.

PB2201

PREVALENCE AND CAUSES OF CLOTTING TIMES PROLONGATION IN PATIENTS WITH TRANSFUSION DEPENDENT BETA THALASSEMIA

I. Tartaglione[1,*], M. Caiazza[1], A. Bonadies[1], D. Roberti[1], M. Casale[1], S. Scianguetta[1], F. Rossi[1], S. Perrotta[1]
[1]Dipartimento della Donna, del Bambino e della Chirurgia generale e specialistica, Università della Campania "Luigi Vanvitelli", Naples, Italy

Background: Thalassemia is traditionally known to be a thrombophilic, rather than hemorrhagic, disorder. In spite of this, prolongation of clotting times are often reported. Understanding if there is a real risk of bleeding, and what this risk can be associated to, is crucial, especially in relation to the frequent referral to surgery (*e.g.* for splenectomy, cholecistecomy). Hepatopathy due to iron overload or HCV infection has been addressed as a main cause of this finding, even though disorders in the clotting profile are often reported also in patients with no alterations of hepatic function. The impairment of factors XI and XII often reported has been hypothesized to be secondary to intravascular haemolysis or multiple transfusions *(Caocci et al, Acta Haematol 1978, Mcfadyen et al, Ann Hematol 2014)*, but no data are available to confirm this supposition.
Aims: To determine the prevalence of clotting disorders in a group of Transfusion dependent Thalassemia (TDT) patients and to assess the correlation with hepatopathy, degree of the hemolysis, transfusion frequency, erythroblastosis, iron chelation.
Methods: TDT patients followed at our center for whom clotting tests were available were included. From chart review data were collected regarding clotting times, demographics, disease history, comorbidities and concomitant medications, iron chelation therapies, iron overload (serum ferritin, LIC, cardiac T2*), liver function tests, hemolysis parameters, hemocromocitometric values. Patients on anticoagulation therapy were excluded.
Results: 56 TDT patients (female 55,35%) were enrolled in our study, mean age 26,02±13,38 years, 17 of them were pediatric. In 20/56 patients (35,71%) prolongation of clotting time was found: this included both prolonged INR (23,21%) and prolonged aPTT ratio (25%); 7 patients (12,5%) had both prolonged INR and aPTT. Subgroup with clotting disorder (group A) was compared to subgroup with clotting times within normal ranges (group B) using T-Test. No differences were found in terms of sex, age, genotype, transfusion interval, hemolysis degree, comorbidities, HCV infection included, iron overload, liver function, erythroblastosis and platelets levels, nor in history of thrombotic complications. No patients had history of hemorrhagic disease. Pretransfusion Hb was lower in patients with prolonged clotting times (p=0,045); none of the patients in Group A was splenectomized (p=0,042).
Summary/Conclusions: In our population clotting disorders were not correlated with hepatic disease, nor hemolysis or transfusions. The mild correlation with lower Hb values and with the lacking splenectomy could be consistent with the known effect of low Ht on lab procedures for clotting tests. In relation to this observation in patients with altered coagulation tests the repetition of clotting test after blood transfusion could be advisable to overcome the low Hb effect.

PB2202

COMPOUND HETEROZYGOSITY FOR HAEMOGLOBIN ADANA AND A-THALASSAEMIA IN GREECE. CLINICAL PHENOTYPE AND GENETIC COUNSELING

S. Theodoridou[1,*], A. Teli[2], E. Yfanti[3], T.-A. Vyzantiadis[4], M. Economou[2]
[1]Thalassemia Unit, Hippokration General Hospital, [2]First Department of Pediatrics, Aristotle University, Thessaloniki, [3]Thalassemia Centre, Laikon General Hospital, Athens, [4]First Microbiology Department, Aristotle University, Thessaloniki, Greece

Background: Haemoglobin (Hb) Adana (HBA2qC.179>A) in interaction with deletional and nondeletional α-thalassaemia mutations leads to HbH or, less commonly to thalassaemia intermedia with clinical manifestations varying from asymptomatic forms to severe anemia. First line screening tests are unable to detect the highly unstable variant. **Aims:** We report two cases of Hb Adana co-inheritance with the a-thalassaemia 3.7 kb deletion - the only α- thal and Hb Adana double heterozygosity cases diagnosed in subjects of Greek origin.
Methods: The first case concerns a 3 year old girl, born from parents referred for genetic counseling at the 11th week of a second gestation. The mother showed an Hb of 10.7g/dl,RBC 4.04 X 10^9 /L, MCV 80,7 fl, MCH 26.4 pg, Hb A2 2.8% and Hb F 1%,with positive inclusion bodies, and her ethnic (Greek) and regional background was of high risk for thalassaemia. The partner came from the same region, and he showed an Hb of 13.8g/dl, RBC 5.88 X 10^9/L, MCV 73,1 fl, MCH 23.5 pg, Hb A2 2.4% and Hb F1% and inclusion bodies were found positive. DNA analysis was requested and, routine investigation was performed in their first offspring. The girl had an Hb of 8.2 g/dl, RBC 3.82 X 10^9/L, MCV 70 fl, MCH 22 pg, Hb A2 1.9% and Hb F 2.3%, while her ferritin levels were 226ng/ml and inclusion bodies were found. On clinical examination she was found to be of normal weight and height for her age, but presented with paleness, icteric sclera and mild splenomegaly. Genetic analysis revealed that the mother carried the α-thalassaemia 3.7 kb deletion defect. The father carried the rare non deletional Hb Adana. As suspected from the haematological data, their offspring was a compound heterozygote for Hb Adana variant in trans to a 3.7 α+ thal deletion.The second case concerns a17-year-old boy, diagnosed with Hb Adana co-inheritance with the a-thalassemia 3.7 kb deletion at the age of 8 years. At diagnosis, findings were compatible with a very mild phenotype and growth was not impaired. The boy retained a mild hypochromic microcytic anemia (Hb~10g/dl, MCV 71 fl, MCH 23 pg, RDW 18.6%, reticulocyte count 5.1%), until adolescence but at the age of 11 transfusion inititation was decided due to marked splenomegaly and limited weight and height gain. For the following years he was transfused approximately once a month, necessitating chelation therapy. Weight, height and pubertal development were normal by the age of 15, but splenomegaly persisted. Splenectomy was decided and transfusions were stopped shortly afterwards. During the following months the boy retained an Hb of 9.5 g/dl, however, he complained of constant fatigue and impaired physical activity and asked to get back on a transfusion program.
Results: In both cases diagnosis was incidental highlighting the mild phenotype. However, the co inheritance of Hb Adana with the 3.7 kb α+ thal deletion is rare, with only the presenting cases in Greece, and in a few other families in Turkey, Southeast Asia, Philippines and Albania. The clinical phenotype of the combination seems to be a mild disease with a non-transfusion-dependent thalassaemia intermedia phenotype. Nonetheless, clinical severity prediction is always a difficult issue and phenotypes may change overtime as demonstrated by the second case described above.
Summary/Conclusions: Long follow-up of such rare cases is necessary in order to gain as much information as possible, so as to offer the best management to the patients and the most accurate genetic counseling.

Thrombosis and vascular biology

PB2203

ANTITHROMBOTIC EFFECTS OF PEPTIDE PGPL IN EXPERIMENTAL THROMBUS FORMATION

M. Grigorjeva[1,*], L. Lyapina[1], T. Obergan[1]
[1]Biology, Lomonosov Moscow State University, Moscow, Russian Federation

Background: Previously, it was established that proline- and glycine-containing peptides have fibrinolytic, anticoagulant activity, inhibit platelet aggregation and thrombin activity *in vitro* and *in vivo*. Besides, it is known that short peptides of this family also have antithrombotic effects.
Aims: To study the influence of Pro-Gly-Pro-Leu (PGPL) and amino-acid leucine on fibrinolytic and anticoagulant blood activity, platelet aggregation and to estimate their possibility to reduce the formation of experimental blood clots.
Methods: Experiments were carried out on white rats (200-250 g) according to the ethical principles of the Helsinki Declaration. Peptide PGPL (1 mg/kg), leucine (0.33 mg/kg - equivalent to its content in PGPL) and saline (control rats) were intranasal entered to rats within 3 days. 1 hour after the last drugs administration we induced the formation of thrombus in v.jugularis (Wessler model). The degree of thrombus formation was estimated on thrombus weight. Fibrinolytic activity and activity of tissue-plasminogen activator (t-PA) of blood plasma were measured by fibrin plate method. Anticoagulant activity (APTT-test) and ADP-induced platelet aggregation were detected by standard methods.
Results: Our experiments demonstrated that preliminary intranasal administration of PGPL (before formation of thrombus) leads to increase of APTT, fibrinolytic and t-PA activity on 18%, 62%, 35% accordingly from control rats. Besides, we observed the decrease of platelet aggregation. Also we indicated the reduction of thrombus weigh in PGPL-treated rats on 68.5% comparatively with control rats. The thrombus weigh after leucine treatment decreased on 30% compared with control rats. But administration of leucine did not change of haemostasis system parameters.
Summary/Conclusions: Thus administration of PGPL enhanced of anticoagulant, fibrinolytic and antiplatelet activity in rats blood plasma. PGPL pretreatment lead to prevention of experimental venous thrombus formation. Therefore, PGPL may be used as perspective anticoagulant and fibrinolytic agent with direct antithrombotic effect.

PB2204

TREATMENT AND OUTCOME OF THROMBOTIC MICROANGIOPATHY IN MALAYSIA

Y.Y. Yap[1,*], K.B. Law[1], P.A.B. Zulkarnain[1], S. Carlo[1], R. Ramli[1], J. Sathar[1], K.M. Chang[1]
[1]Department of Haematology in Ampang Hospital, Ministry of Health, Selangor, Malaysia

Background: Thrombotic Thrombocytopenic Purpura (TTP) is a potentially lethal disease that there is still no promising cure in this era. The ADAMTS-13 deficiency or defect in the disease has enabled clinician to recognize another entity which is Thrombotic Microangiopathy (TMA). This entity includes TTP, typical Haemolytic Uraemic Syndrome (HUS), Cancer associated TMA, Atypical HUS, Pregnancy TMA, SLE related TMA and Transplant TMA.
Aims: This study is to focus on the treatment among the TMA and the outcome of the disease.
Methods: The data was collected from year 2012 to 2016 from Ampang Hospital via the electronic hospital information system (EHIS) and external records traced from Haemostasis laboratory in Ampang Hospital as well as from other hospitals nationwide.
Results: There were total of 243 suspected TMA cases, encompassing 97 (39.9%) males and 146 (60.1%) females. The median age for this cohort was 34 years. Only 54 (24.15%) patients were diagnosed as TTP based on ADAMTS-13 activity ≤10%. Treatments were evaluated by using complete case details from Ampang Hospital cohort (69 cases). From this cohort, only 59 cases had ADAMTS-13 activity testing. There were 24% Primary Acquired TTP, 5% typical HUS , 3.4% atypical HUS, 3.4% Pregnancy TMA, 3.4% SLE related TMA, 20.3% Transplant TMA , 1.7% Cancer associated TMA and 37% TMA of other causes. The average plasma exchange was 8.4 cycles, and was higher in patients with ADAMTS-13 activity of ≤10% (11.4 cycles) as compared to those with ADAMTS-13 >10% (7.7 cycles). No infectious diseases were transmitted as a result of plasma exchange or plasma infusion. Treatments used in the patients included immunosuppressant therapy like methylprednisolone (85.5%), monoclonal antibody like rituximab (36.2%), bortezomib (11.6%), cyclophosphamide (10.1%), cyclosporine (10.1%), and vincristine (26.1%). The survival outcome seemed to be worse among the transplant TMA in comparison to other groups (log-rank, p<0.0001). Transplantation was also associated with higher odd of death among TMA cases (OR: 14.8571, 95% CL: 1.7385, 126.9707). Those with confirmed TTP was inevitably doing better than the others in terms of overall survival (log-rank, p=0.0299). The odds of death was 4.36 times higher in patients with ADAMTS-13 activity >10% (OR: 4.36, 95% CL: 1.0961, 17.3714), indicating secondary TTP may have inferior treatment and disease outcomes than primary TTP like congenital or acquired TTP. Besides, the complications of the disease were also evaluated which revealed 26.9% of renal failure and 52.2% of neurological deficit. Furthermore, 8.7% were complicated by Venous Thromboembolism, either provoked or spontaneous. The odds of relapse is 2.9 times higher given the ADAMTS-13 activity ≤10% to ADAMTS-13 activity >10%.
Summary/Conclusions: This study illustrated that the standard treatment like plasma exchange and immunosuppressant therapy are only effective in genuine TTP whereas those masquerading TTP (TMA) would be more challenging to be tackled in terms of improving the outcome. The task to investigate other types of TMA prospectively will be highly desirable in the future.

PB2205

ANTIPHOSPHOLIPID ANTIBODY PROFILE AND ORGAN INVOLVEMENT IN CRITALLY ILL PATIENTS WITH AUTOIMMUNE DISEASES

P. Zambrano[1,2,*], J. Aponte[1], A. Sanchez[2], M.T. Ospina[2], Y. Forero[1], J. Carrizosa[3], E. Aviles[4], A. Cartagena[1], C. Zapata[1], C. Gamboa[1]
[1]Universidad de La Sabana, [2]Hospital Universitario de la Samaritana, [3]Fundación Santa Fe De Bogotá, Bogota, [4]Universida de La Sabana, Bogotá, Colombia

Background: Antiphospholipid antibodies (APA) are a group of proteins directed against the phospholipids of cell membranes, such as cardiolipins or phospholipid binding proteins. APA presence provokes microvascular, arterial or venous thrombotic events indicating somehow the relationship between the immune system, the hemostatic system, and the inflammatory response. It has been suggested that their presence in a critically ill patient is related to thrombotic manifestations, organ dysfunction, and death.
Aims: The aim of this study was to evaluate the prevalence of antiphospholipid antibodies in critically ill patients with autoimmune diseases and the rate of organ involvement.
Methods: Retrospective and descriptive study of patients admitted to the intensive care unit of Hospital Universidad de la Samaritana between 2008 and 2016, in Bogotá, Colombia.
Results: A total of 79 patients were found to have systemic lupus erythematosus (SLE), antiphospholipid syndrome and vasculitis. 17 patients (22%) were positive for antiphospholipid antibodies. Of these, 76% were women and mean age was 38 years (18-63 years). APA profiles showed positivity with this distribution: one positive antibody, n=9 patients (53%) (lupus anticoagulant antibody being the most common), two positive antibodies in n=4 patients (23%) and three positive antibodies in n=4 patients. Anemia (100%), monocytosis (64%), thrombocytopenia (40%) and prolonged INR (17%) were found in 88% of patients on admission to the ICU. In descending order, other organ involvement was found to be: pulmonary and renal dysfunction (70%), shock (53%), central nervous system involvement (41%), cardiovascular (23%), and gastrointestinal (22%). 82% of this cohort had positive anti-nuclear antibodies (ANA) and 23% anti-cytoplasmic antibodies (ANCA). 100% of patients had elevated C-reactive protein (CRP), and APACHE II score average was 11 points (Table 1).

Table 1.

n	Gender	Age (years)	Lupus anticoagulant	Anticardiolipin antibodies	Antiphospholipid antibodies	Anti - B2 microglobulin
1	Female	26	Not available	IgG	Not available	Not available
2	Female	25	Positive	IgM	No available	Not available
3	Female	63	Negative	Negativo	IgM	Not available
4	Female	19	Positive	Negativo	IgG	Not available
5	Male	63	Positive	Negative	Not available	Not available
6	Female	61	Positive	IgG	Not available	Negative
7	Male	62	Positive	Negativo	Not available	Negative
8	Female	30	Positive	Negative	Not available	Negative
9	Male	53	Positive	Negative	Not available	Not available
10	Male	53	Positive	IgM/IgG	Not available	Negative
11	Female	18	Positive	IgM	Negative	Negative
12	Female	29	Not available	Not available	Not available	IgG
13	Female	18	Negative	IgM	IgG	IgG
14	Female	20	Positive	IgG	IgG	Not available
15	Female	49	Negative	IgG	IgG	IgG
16	Female	22	Positive	Negative	Negative	Not available
17	Female	35	Positive	Negative	Negative	Negative

Demographic data and antiphospholipid antibody distribution.

Summary/Conclusions: Hematologic, renal and pulmonary involvement are the most commonly compromised in patients with antiphospholipid antibodies positivity in patients with autoimmune diseases in the ICU. Based on these results, a prospective study is proposed in order to evaluate the presence of APA and their impact on mortality and multi-organ dysfunction in these patients.

PB2206

PREVALENCE OF ANTIPHOSPHOLIP ANTIBODY AND HBA1C IN T2DM WITH DIABETIC VASCULAR COMPLICATIONS

T U. Nwagha[1,*], O. Agwu[1]
[1]Haematology & Immunology, University Of Nigeria Teaching Hospital, Enugu, Nigeria

Background: Antiphospholipid antibodies (APLS) have been implicated in vascular (arterial, venous or both) thrombosis Diabetes Mellitus (DM), as a disease entity has been associated with hyper-coagulable and pro-thrombotic states, with studies showing an increased procoagulant state and thrombotic events especially in poorly controlled Type 2 Diabetes Mellitus (T_2DM).
Aims: The aim of the study is to assess the APLS and HbA1c levels and evaluate the correlation between APLS levels and HBA1c in T_2DM patients with diabetic vascular complications.
Methods: This was a cross-sectional study of subjects with T2DM attending the diabetic clinic of University of Nigeria Teaching Hospital. A total of two hundred and ten (210) subjects were recruited for this study. There were grouped into three (complicated T2DM, uncomplicated T2DM and health control. Each had 70 subjects matched for sex and age. Lupus anticoagulant (LA) was assayed using DRVVT (technoclone GmbH Austria) IgGβ2GPI-ACA was assayed using ELISA test kit (Genway Bio-tech San Diego USA), HbA1C was assayed using D10^{TM} haemoglobin analyzer. Ethical clearance was obtained from ethical committee UNTH.
Results: The prevalence of LA was 7.1%, 4.3% and 4.3% for complicated T2DM, uncomplicated and healthy control subjects respectively, while the prevalence of IgG-B2GPI ACA was 4.3% in all groups. The mean HbA1C were 8.2(1.5), 8.0 (1.7) , 5.6 (0.38) for complicated ,uncomplicated T2DM and control subjects respectively. ANOVA showed a significance difference in mean HbA1C among complicated uncomplicated T2DM and healthy controls. Post hoc analysis showed this difference was between complicated T2DM and healthy controls (p<0.001, 95%,CI-3.0 to -2.1) and in uncomplicated T2DM and healthy control subjects (p<0.001,95%,CL-2.8 to -2.0) there was a significant correlation between HbA1C and IgGβ2GPI-ACA for complicated T2DM(r=0.316),P=0.008) and uncomplicated T2DM (r=0.316),P<0.001)
Summary/Conclusions: The study did not find any causal or other association between T2DM and the occurrence of APLS positivity, however, APLS may be simply an aggravating factor for vascular complications especially in poor controlled T2DM

PB2207

VWF THR789ALA GENETIC VARIANTS CORRELATE WITH DISEASE PHENOTYPE IN EGYPTIAN PATIENTS WITH ACUTE CORONARY SYNDROME

N. Osman[1,*], M. Younes[1], R. Yaseen[1], A. Fathy[1]
[1]Clinical Pathology, Menoufia University, Shebin Elkom, Egypt

Background: von Willbrand factor antigen level (vWF: Ag) was shown to contribute to the risk of cardiovascular disease. vWF Thr789Ala single nucleotide polymorphism is thought to affect factor level and function.
Aims: This study aimed to investigate the impact of genetic variants at that position on the risk of acute coronary syndrome (ACS).
Methods: The study included 112 patients of ACS; 31 with unstable angina (UA) and 81 with myocardial infarction (MI) as well as 118 healthy controls. vWF: Ag level was measured by ELISA. The gene analysis was carried out by polymerase chain reaction using restriction fragment length polymorphism (RFLP-PCR) principles.
Results: vWF: Ag levels were significantly higher in MI (111.68±24.77 IU/dl) and UA (110.27±23.44 IU/ml) patients compared to healthy controls (71.13±13.72 IU/dl), p <0.001 for both groups, The majority of patients with UA (80.6%) were Ala789 homozygous, 6.5% were Thr789Ala heterozygous and 12.9% were Thr789 homozygous. Regarding the MI group, Ala789 genotype was present in 34.6%, Thr789Ala genotype was the predominant genotype and was seen in 48.1% of patients and Thr789 homozygous was present in 17.3% of patients. The genotype frequency in the control group was as follow; 47.4% were Ala789 homozygous, 33.1% were heterozygous and 19.5% were Thr789 homozygous. The genotype distribution was significantly different among the 3 groups, p<0.001, and between the groups with UA and MI, p <0.001. Ala789 homozygous genotype was an independent risk factor for UA while the Thr789Ala genotype was shown as an independent risk factor of MI.
Summary/Conclusions: vWF Thr789Ala genotype is independent risk factor for UA and has significant impact on the type of myocardial ischemia. It should be incorporated in a risk assessment model to identify individual patient risk and guide the management plan.

PB2208

THE INFLUENCE OF FIBRINOGENASE ISOLATED FROM THE ANTARCTIC SCALLOP ON BLOOD COAGULATION

N. Raksha[1,*], D. Gladun[1], T. Ishchuk [1]
[1]Biochemistry, Educational and Scientific Center "Institute of Biology and Medicine" Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

Background: At the present time, cardiovascular diseases such as acute myocardial infarction, ischemic heart diseases, and stroke are the most important causes of the human mortality around the world. Thrombosis is probably the most common symptom among cardiovascular diseases. Thrombolytic agents have been extensively used in the therapeutic treatment of thrombosis. But most of them have some serious shortcomings, including limited efficacy, short plasma half-life, large therapeutic dose or allergic response. Considering the global burden, the search continues for a safe and cheap thrombolytic agent to treat cardiovascular diseases. To date, many investigators have been trying to improve the safety and efficacy of thrombolytic therapy. Fibrinogenolytic enzymes or fibrinogenases because of their role in dissolving of blood clots as well as prevention their formation have attracted special medical and scientific attention. Enzymes that affect hemostasis have been isolated from different sources. In recent years, special attention is paid to the hydrobionts from the Antarctic region which are poorly explored and potentially can be a valuable source of new bioactive compounds, in particular enzymes.
Aims: The main goal of current research was to test the effect of fibrinogenase from marine hydrobiont the Antarctic scallop *Adamussium colbecki* on platelet aggregation and blood coagulation.
Methods: Fibrinogenase from the crude tissue extract of *A. colbecki* was isolated by three-step procedure (affinity chromatography on SBTI-sepharose following affinity chromatography on Blue-Sepharose and size exclusion chromatography on Superdex 75-PG). Platelet aggregation was determined by AT-02 aggregometer (Medtech, RF). The platelet count was adapted to $2.5x10^5$ platelets/μL with platelet-poor plasma. Then, fibrinogenase (12.5 μg/mL or 6.25 μg/mL) was added 2 min before the addition of the platelet aggregation inducer ($5x10^{-6}$ M ADP). The changes in light transmittance were continuously monitored during 8 min, and the percentage of aggregation, in the presence of the samples, was calculated comparing the transmittance against the controls. Activated partial thromboplastin time (APTT) and prothrombin time (PT) were measured in CLOTimer analyzer.
Results: According to our result investigated enzyme inhibited ADP-induced platelet aggregation and the inhibition increased with increasing concentration of the enzyme. Data analysis revealed a significant (p<0.05) inhibition of ADP-induced platelet aggregation by 80.5% for 12.5 μg/mL of fibrinogenase and by 31.8% for 6.25 μg/mL of fibrinogenase. Isolated fibrinogenase may inhibit platelet aggregation by hydrolyzing the Aα-chain of fibrinogen to prevent fibrinogen from combining with fibrinogen receptor on platelet membrane. In addition, fibrinogen degradation products may act as competitive inhibitors of platelet–fibrinogen bridging formation. We also investigated the effect of fibrinogenase on blood coagulation by determination of APTT and PT. According to our result APTT increased in 2.25 and 1.25 times at the concentration of fibrinogenase of 12.5 μg/mL and 6.25 μg/mL, respectively. The fibrinogenase also prolonged PT from 18 s to 68 s when the concentration of enzyme was 6.25 μg/mL.
Summary/Conclusions: Further investigations of fibrinogenase from A. colbecki are interesting and would probably help to develop new therapeutic agents to treat thrombotic disorders.

PB2209

IMPORTANCE OF MONITORING PATIENTS WITH DIRECT ORAL ANTICOAGULANTS

L.F. Ávila Idrovo[1,*], A. Bernardo Gutierrez[1], A. Caro Gómez[1],
D. Martinez Carballeira[1], I. Soto Ortega[1]
[1]Hematology, Hospital Universitario Central de Asturias, Oviedo, Spain

Background: A major advantage of these agents is the lack of a requirement for monitoring, due to less variability in drug effect for a given dose, however it´s recommended monitoring the drug for Rivaroxaban Apixaban and Endoxaban use anti-Xa chromogenic studies and for Dabigatran Hemoclot thrombin inhibitor and Ecarin clotting time (DTI test).
Aims: Determine the effectiveness of laboratory tests to monitor patients treated with direct oral anticoagulants.
Methods: We conducted a retrospective study with 227 patients who received direct oral anticoagulants (DOACs) between January 2015 and December 2016. One hundred eighteen patients (52%) receive Rivaroxaban, fifty patients (22%) receive Dabigatran and fifty nine patients receive Apixaban (26%). We analyzed the variables that's increases the bleeding risk such as age, weight, prothrombin time (PT) and activated partial thromboplastin time (aPTT), therapeutic range of the drug, and measurement of serum creatinine.
Results: We found 10% of toxicity with Dabigatran, a 7% with Rivaroxaban and a 3% with Apixaban. Thirty-five patients (15%) developed bleeding of which 11% patients had a minor bleeding and a 4% of patients had a mayor bleeding, we also found that 6% of patients with Dabigatran, 2.5% with Rixaroxaban and 1.5% with Apixaban developed thrombotic episodes. Twenty percent of patient didn't have therapeutic range of the drug. For each DOACs is shown in Table 1. When we analyzed the patients who had hemorrhage we found that all patients with Dabigatran prolonged aPTT and the PT in 80%, for other DOACs is shown in Table1. A retrospective case-matched analysis was performed comparing 35 patients who developed bleeding with an equal number of patients who did, case and control groups were matched according to age, weight and measurement of serum creatinine we didn´t found significant difference.
Summary/Conclusions: In our series, in patients with dabigatran and who suffered bleeding, we found a significant prolongation of aTTP and PT, demonstrating the importance of laboratory tests prior to the administration of these agents and in emergency situations, for these reason should be include PT

and aPTT, therapeutic level of the drug and creatinine measurement, within the emergency and control laboratory tests in patients that receive DOACs.

Table 1.

Variable	Apixaban	Rivaroxaban	Dabigatrán
percentage	25.9%	51.9%	22%
toxicity	3.3%	6.7%	10%
thrombotic episodes	1.6%	2.5%	6%
percentage out of therapeutic range	8.4%	24.5%	22%
prolonged aPTT	8.4%	2.5%	80%
prolonged PT	16.9%	21%	4%
Bleeding	(35) 15.4%		
percentage	34.2%	20.8%	7.8%
prolonged aPTT	8.3%	22.2%	100%
prolonged PT	25%	33.3%	80%
median therapeutic range	177	142	154
median serum creatinine	1mg/dl		
median age	81

HEREDITARY RISK FACTORS OF VENOUS THROMBOEMBOLISM IN YOUNG WOMEN TAKING ESTROGEN DRUGS

A. Chechulova[1,*], S. Kapustin[2], S. Karpich[2], V. Shmeleva[2], V. Soldatenkov[2], L. Papayan[2], V. Soroka[1], P. Chechulov[3]
[1]Vascular surgery, Dzhanelidze Research Institute of Emergency Medicine, St. Petersburg, [2]Russian Research Institute of Hematology and Transfusiology, [3]Dzhanelidze Research Institute of Emergency Medicine, St. Petersburg, St. Petersburg, Russian Federation

Background: Estrogens are recognized as the most common risk factor of venous thromboembolism (VTE) in young women. The cumulative risk of VTE in patients taking estrogens is significantly increased in carriers of inherited thrombophilia. However, the known hereditary risk factors – mutations FV Leiden and FII G20210A could be detected in only 20-30% of patients with VTE.
Aims: To identify the most common hereditary risk factors of VTE in young women taking estrogen drugs.
Methods: We examined 133 young women with acute VTE (mean age 37.4 years; 16-45), who were genotyped by PCR-RFLP method for DNA polymorphism in 9 genes: FI-A Thr312Ala, FI-B -455 G/A, FII 20210 G/A, FV 1691 G/A, FXII 46 C/T, FXIII-A Val34Leu, PAI-1 -675 4G/5G, EPCR Ser219Gly, TPA 311bp Ins/Del. We compared the distribution of studied genotypes in three groups of patients with VTE: taking estrogens (n=30, group 1), with idiopathic VTE (n=42, group 2) or having other risk factors (n=61, group 3). Intergroup differences in genotype frequencies were assessed by Fisher's exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated with SPSS software version 17.0 (SPSS Inc, Chicago, IL, USA).
Results: The frequencies of prothrombotic genotypes in groups 1, 2 and 3, respectively, were: FV 1691GA – 20.0%, 21.4% and 13.1%; FII 20210GA – 10.0%, 9.8% and 7.1%; FI-B –455AA – 10.0%, 2.4% and 1.6%; FI-A 312Ala/Ala – 13.3%, 14.3% and 13.1%; TPA 311bp Ins/Ins – 16.7%, 28.6% and 31.1%; PAI-1 -675 4G/4G – 36.7%, 42.9% and 27.9%; EPCR 219Ser/Gly – 16.7%, 19.0% and 23.0%; EPCR 219Gly/Gly – 3.3%, 7.1% and 0.0%; FXII 46TT – 13.3%, 0.0% and 9.8%; FXIII-A 34 Leu/Leu – 3.3%, 21.4% and 9.8%. Significant differences between the groups have been detected only for the FXIII-A 34Leu/Leu variant, which was more frequently found in patients with idiopathic VTE than in the group with estrogens (OR=6.5; 95% CI: 1.2-63.4; p=0.012) and women having other risk factors (OR=2.2; 95% CI: 0.8-7.6; p=0.05). The frequency of FI-B –455AA genotype in young women with DVT developed after taking estrogen drugs was 4- and 6-fold higher, respectively, when compared to the group with idiopathic VTE and patients having other risk factors (10.0% *vs* 2.4%; OR=4.1, 95% CI: 0.02-2.2, p=0.16 and 10.0% *vs* 1.6%; OR=6.6, 95% CI: 0.7-67.0, p=0.067).
Summary/Conclusions: FV Leiden and FII 20210G/A mutations as well as the FI-B -455AA genotype are frequently seen in young women with DVT developed after taking estrogen drugs. Further studies are needed to clarify genetic risk factors contributing to VTE development in this group.

KNOWLEDGE AND ATTITUDE OF MEDICAL DOCTORS ON ANTICOAGULATION THERAPY IN TERTIARY HOSPITALS IN NIGERIA

T.U. Nwagha[1,*], R. Anakwue[2], O. Ukpabi[3], E. Onwubuya[4], N. Obeka[5], I. Okoye[6], B. Azubuike[6]
[1]Haematology & Immunology, [2]Internal medicine, University Of Nigeria Teaching Hospital, Enugu, [3]Internal medicine, Abia state Teaching Hospital, Umuahia, [4]Internal medicine, Nnamdi Azikiwe Teaching Hospital Nnewi, Awka, [5]Internal medicine, Federal Medical center , Abakiliki, [6]Internal medicine, Amaku Specialist hospital, Awka, Nigeria

Background: Thromboembolic and hypercoagulable diseases are common life-threatening but treatable problems in hospital practice. The most effective and economical approach to decreasing the burden of VTE is to prevent the development of DVT and PE in patients especially in acutely ill hospitalized medical patients. Health care providers in Nigeria may have significant gaps in their anticoagulation knowledge that could affect their decision to prescribe anticoagulation therapy as there are no national guidelines on the use of anticoagulation in Nigeria.
Aims: The purpose of this present study was to examine the knowledge and attitude of medical doctors on anticoagulation in tertiary hospitals in Nigeria.
Methods: The present study is a multicentre survey of the use of anticoagulants among clinicians in South East Nigeria. A pretested questionnaire was administered to clinicians in six tertiary hospitals in the south-east of Nigeria. The following institutions participated in the survey: University of Nigeria Teaching Hospital Enugu, Federal Medical Centre, Abakaliki, Federal Medical Centre Umuahia, Abia State Teaching Hospital, Aba, Amaku Specialist Hospital, Awka and Nnamdi Azikiwe Teaching Hospital, Nnewi. The Likert scale which is in grades from one to five: 1 strongly disagree, 2 disagree,3 neutral,4agree,5 strongly disagree was used. To determine the agreement degree three levels were identified (high medium and low).
Results: There were 528 respondents. 378 of them were males (71.6%) and 150 were females (28.4%). 31.1% of the respondents, were junior residents and the consultants represented only 20.6% of the respondents. Most of the respondents,189 (35.8%) had less than 5 years clinical experience while the least of the respondents (8.7%) had between 16-20 years clinical experience We observed that most respondents irrespective of their job grades didn't know about Fondaparinux and the DOAC (except those in the specialist - registrar job grades) as the overall p=(0.000),<0.05 and were significant. We also observed that responses were divided on malignancy as an indication for anticoagulation. The overall P=0.002, <0.05 and was significant. The p valve for other indications for anticoagulation >0.05 and was not significant. The majority knew of prothrombin test and p valve was 0.03, less than alpha value of 0.05 and was significant. On the contrary, Majority does not know about anti-Xa assay, p-value=0.02, <0.05, was also significant. Their affirmative response on the mode of action as one of the differences showed a p=0.000, <0.05, was significant. On the contrary, the non-affirmative response to drug and food interaction, p=0.03, was also significant. Based on results of the statement analysis, the variables were ranked according to the value of their mean. All except one variable had p-values of <0.05. The statement "Do you think anticoagulation therapy/prophylaxis is clinically important" had the highest mean of 4.60 and had a high degree of agreement. The statement "Should hospital inpatient with >3 days admission routinely receive anticoagulation?" had the lowest mean of 2.27 with a p-value of 0.015 had a low degree of agreement.
Summary/Conclusions: There is a need to upscale knowledge attitude and practice of the use anticoagulation agents especially the NOACs through well-articulated CME educational activities. A limitation of this study is the relatively small number of study participants and some subspecialties that were not reflected in this survey.

INTERLEUKIN -10 GENE POLYMORPHISMS AND THE RISK OF UNPROVOKED DVT IN EGYPTIAN PATIENTS

H. Ellithy[1,*], G. Shaheen[2], S. Elmoamly[1]
[1]Internal medicine- clinical Hematology Unit, [2]Clinical pathology, Kasr Al-ainy school of medicine- Cairo university, Cairo, Egypt

Background: Thrombosis is often multifactorial, caused by both genetic and acquired risk factors. The inflammatory process is linked to pathogenesis of venous thrombosis. Venous thrombosis is considered to be mediated by an imbalance in proinflammatory as compared with anti-inflammatory molecules. One of the important anti-inflammatory cytokine is interleukin-10 (IL-10) with important immunoregulatory functions. Primarily, IL-10 counterbalances the potentially harmful effects of tumor necrosis factor α (TNFα) and other pro-inflammatory mediator such as IL-1b, IL-6, and IL-8 from monocytes/macrophages. Three important single nucleotide polymorphisms (SNP) affect IL-10 expression, including: 1082 A/G, 819 C/T, and 592 C/A. Studying the association between genetic polymorphisms of anti-inflammatory cytokines such as IL-10, and venous thrombosis may suggest using of polymorphisms as a predictive genetic marker of future VTE.
Aims: The objective of this study was to evaluate a possible association between IL-10 -1082A/G, and -592C/A polymorphisms with DVT.
Methods: The study was conducted on 115 patients with symptomatic DVT proved by venous duplex ultrasound; divided into two cohorts: group A included

60 patients with unprovoked DVT, and group B included 55 patients with provoked DVT. Gene mutations for IL-10 -1082A/G, and -592C/A were performed using PCR-restriction fragment length polymorphism assay. We studied the association between IL-10 gene polymorphisms and occurrence of either provoked or non-provoked DVT. We also investigated the link between these polymorphisms and the recurrence of DVT and family history of DVT.
Results: in our study IL101082AG gene analysis revealed that mutant genotypes distribution is statistically significant different compared to the wild genotype distribution, being higher in group A (with unprovoked DVT) than in group B (with provoked DVT); as GG genotype was detected in 14 patients (63.6%) *versus* 8 patients (36.4%) in group A and B respectively (P value=0.037); AG genotype was detected in 30 patients (63.8%) compared to 17 patients (36.2%) in group A and B respectively (P value=0.007). However, there is no correlation was found between IL101082 mutant genotypes distribution and VTE recurrence (P value= 0.738 and 1 respectively) or positive family history of VTE (P value= 0.101 and 0.714 respectively), compared to wild genotype. IL10592AC gene analysis showed that mutant genotypes (GG and AG) distribution showed no statistically significant difference (p value= 0.43 and 0.687 for GG and AG genotypes respectively) compared to wild genotypes distribution, also there is no correlation was found between IL10592AC mutant genotypes distributions and VTE recurrence (P value= 1 and 0.284 for GG and AG genotypes respectively) or positive family history of VTE (P value= 0.67 and 1 for GG and AG genotypes respectively), compared to wild genotype (AA).
Summary/Conclusions: I IL101082AG gene polymorphism is associated with risk of unprovoked DVT, however it is not associated with either risk of recurrence or positive family history.

PB2215

CATASTROPHIC ANTI-PHOSPHOLIPID SYNDROME TRIGGERED BY SEPSIS. A PROSPECTIVE CASE STUDY HIGHLIGHTING BIOLOGICAL CONCEPTS AND MANAGEMENT STRATEGIES IN THIS COMPLEX AND LIFE THREATENING DISEASE
M. Hua[1,*]
[1]Haematology, Liverpool Hospital, Sydney, Australia

Background: Catastrophic antiphospholipid syndrome (CAPS) is a rare and life threatening event characterized by widespread intravascular thrombosis and multi-organ failure. Rarely is CAPS associated with bleeding diathesis, but has been reported in cases with severe thrombocytopenia and acquired prothrombin inhibitors. APS auto-antibodies are heterogeneous and may undergo post-translational modification during antigen stimulation altering its pathogenicity and thrombotic risk. Sepsis and associated disseminated intravascular coagulation is a known phenomenon where cytokines influence pro-coagulant and anti-coagulant pathways on multiple levels to induce haemostatic chaos.
Aims: Demonstrate the role of sepsis in triggering life threatening CAPS, and highlight the management strategies used in this highly complex and fatal disease.
Methods: Prospective case study illustrating two separate atypical CAPS presentations and the management strategies employed. *1st episode (2015):* 54F with long standing 27 years of triple positive APS, pro-thrombotic history with recurrent thrombosis despite optimal anticoagulation. Her pro-thrombotic equilibrium was altered after a respiratory tract infection where she presented with severe headaches. Subsequent investigations demonstrated multiple atraumatic intra-cranial haemorrhages followed by concurrent extensive cerebral venous thrombosis. *2nd episode (2017):* She presented with subdural haemorrhage, preceded by fevers and respiratory symptoms. She then developed pleuritic chest pain and dyspnoea after temporary cessation of anticoagulation for 24 hours. Imaging confirmed multiple pulmonary emboli with areas of infarction. Respiratory symptoms worsened with progressive interstitial ground glass changes on CT consistent with atypical pulmonary infection. Shortly after low therapeutic anti-coagulation she developed acute abdominal pain and hypotension. CT confirmed significant bilateral adrenal haemorrhages. *Management Strategies:* (A) Rapid reduction in APS pathogenic auto-antibodies via plasma exchange, B cell depletion therapy and immune modulation. (B) Treatment of underlying infectious trigger. (C) Judicious anticoagulation with anti-Xa monitoring and (D) long term hydroxychloroquine and statin therapy.
Results: The two life threatening presentations of CAPS were triggered by an infectious event, supporting the biological concept that anti-phospholipid antibodies can be immune modulated altering his pathogenic capabilities creating haemostatic havoc. There are similarities and a degree of overlap with sepsis and the pathophysiology behind disseminated intravascular coagulopathy. Rapid reduction in the pathogenic auto-antibodies using combination plasma exchange, immune modulation and B cell depletion therapy is effective in this acute setting. Judicious anticoagulation and treatment of the precipitating infection is important in turning off the immune response driving this life-threatening coagulopathy.
Summary/Conclusions: CAPS is rare and life threatening, often triggered by an infectious event, trauma or temporary cessation of anticoagulation. It requires prompt recognition and timely commencement of therapy.

PB2216

HAEMATOLOGICAL CORRELATES OF ISCHEMIC STROKE AND TRANSIENT ISCHEMIC ATTACK : LESSONS LEARNED
H. Gunasekara[1,*], I. Pathiraja[2]
[1]Health, Teaching Hospital- Kegalle, Kegalle, [2]Health, Provincial Department of Health Services, North Western Province, Sri Lanka

Background: Haematological abnormalities are known to cause Ischemic Stroke or Transient Ischemic Attack (TIA). The identification of haematological correlates plays an important role in management and secondary prevention
Aims: The objective of this study was to describe haematological correlates of stroke and their association between stroke profile. The haematological correlates screened were Lupus Anticoagulant, Dysfibroginemia, Paroxysmal nocturnal haemoglobinurea (PNH), Sickle cell disease, Systemic Lupus Erythematosis (SLE) and Myeloploriferative Neoplasms (MPN).
Methods: A cross sectional descriptive study was conducted in a sample of 152 stroke patients referred to haematology department of National Hospital of Sri Lanka for thrombophilia screening. Following tests were performed to assess each hematological correlates (Table 1).

Table 1.

Hematological correlate	Tests performed
Lupus anticoagulant	Diluted Russels Viper Venom Test and Kaolin clotting time
Sickle cell disease	Full blood count (FBC), blood picture and sickling test and High Performance Liquid Chromatography
Paroxysmal nocturnal haemoglobinurea	FBC, blood picture, Ham test and flowcytometry
Myeloploriferative neoplasms	FBC , blood picture, Janus Kinase 2 (V617F) mutation analysis, erythropoietin level and bone marrow examination
Dysfibrinogenaemia	TT, fibrinogen antigen test, clot observation and clauss test
Systemic lupus erythematosis	Anti nuclear antibodies

Results: Among study sample, 134 patients had strokes and only 18 had TIA. The recurrence of stroke/TIA was observed in 13.2% of patients. The majority of patients (94.7%) have had radiological evidence of thrombotic event. One fourth of patients had past thrombotic events while 12.5% had family history of thrombosis. Out of haematological correlates screened Lupus anticoagulant was the most common haematological correlate (n=16) and dysfibrigonaemia(n=11) had the next high prevalence. One patient was diagnosed with Essential thrombocythaemia and one with SLE. None of the patients were positive for screening tests done for sickle cell disease and PNH.
Summary/Conclusions: The Haematological correlates were identified in 19% of our study sample. Among stroke profile only presence of past thrombotic history was statistically significantly associated with haematological disorders (P= 0.04). Therefore hematological disorders appear to be an important factor in etiological work up of stroke patients particularly in patients with past thrombotic events.

PB2217

ANTIPLATELET AND FIBRINOLYTIC EFFECTS OF ARGININE-CONTAINING PEPTIDES IN HEALTHY RATS AND RATS WITH METABOLIC SYNDROME
Y. Song[1,*], M. Grigorjeva[1], T. Obergan[1]
[1]M.V.Lomonosow Moscow State University, Moscow, Russian Federation

Background: Currently, the number of diabetes, hypercholesterolemia, metabolic syndrome (MS) patients has increased sharply in the world. MS is metabolic disorders with increase of cholesterol and glucose levels, dyslipemia, endothelial dysfunction. This is accompanied by an increase in blood clotting, including platelet aggregation strengthening and reducing the activity of the plasminogen activator. Thus, the MS may predispose to venous thrombosis. It is known that, regulatory oligopeptides involved in the conservation normal functional activity of coagulation, anticoagulation, insular systems of the organism, fat metabolism. It is also known that some amino acids, particularly arginine, improve rheological properties of blood and reduce platelet aggregation.
Aims: To study the effect of tripeptides Pro-Arg-Gly and Gly-Arg-Pro, containing arginine in the molecule, on platelet aggregation and tissue plasminogen activator (t-PA) activity in a healthy organism and the development of the experimental MS.
Methods: Experiments were carried out on Wistar rats weighing 300-350 g in accordance with the ethical principles of the Helsinki Declaration. Two groups of animals were used: healthy rats and rats with experimental MS. Peptides were intranasal injected in doses of 1 mg / kg once daily for 5 days. 0.85% NaCl solution was injected to control rats in the same time frame. MS in rats was caused by a hyper-cholesterol fat-rich diet (FD) for 6 weeks. Blood samples were taken from the jugular vein 1 hour after the last drug administration. Activity of t-PA (fibrin plate method) and ADP-induced platelet aggregation (standard method) were measured in blood plasma.
Results: The intranasal administration of peptides Gly-Arg-Pro, and Pro-Arg-Gly to healthy animals resulted a reduction of platelet aggregation by 23% and 52% compared with the control. Both peptides induced enhancement t-PA activity of 2 or 3.5 times respectively. In rats with experimental MS these effects were preserved, besides, platelet aggregation was decreased by 27% (Pro-Arg-Gly) and 38% (Gly-Arg-Pro) compared with the control.

Summary/Conclusions: We concluded that intranasal administration of tripeptides Pro-Arg-Gly and Gly-Arg-Pro to organism of healthy rats and in rats with experimental MS show antiplatelet and fibrinolytic effects of the blood. Thus, arginine-containing peptides could potentially be used as antithrombotic drugs that protect the organism from the blood coagulation and thrombus formation.

PB2218

THE PRINCIPAL COMPONENT ANALYSIS USING CALIBRATED AUTOMATED THROMBOGRAM PARAMETERS AS A POTENTIAL QUALITY CONTROL FOR MEASURING PROCOAGULANT ACTIVITIES OF IMMUNOGLOBULINS

H. Oh[1,*], C. Ahn[1], S. Han[1], H. Song[1], K. Han[1], G. Min[1], J. Kim[1], S. Park[1], K. Jung[1]
[1]Blood Products Division, National Institute of Food and Drug Safety Evaluation, Cheongju-si, Korea, Republic Of

Background: The calibrated automated thrombogram (CAT) is a method to monitor the generation of thrombin. It can be described by four variables; lag time, peak thrombin, time to peak, and velocity index. Currently, due to thromboembolic event related risks of immunoglobulins, the CAT is widely used to quantify the thrombogenic potential associated with immunoglobulin manufacturing processes and products. However, there is currently no officially approved method for such assessments and even this results are highly variable in inter-laboratories comparison. In this study, to obtain a summary score, we applied the principal component analysis (PCA) for these four outcomes measured from CAT method. The PCA is a statistical procedure concerned with elucidating the covariance structure of a set of variables. In particular it allows us to identify the principal directions in which the data varies.
Aims: In this study, our interest is to apply PCA method in order to find appropriate dose related with CAT variables and to reduce variation of procoagulant values in Immunoglobulin products.
Methods: The CAT are measured in a 96 well plate fluorometer equipped with a 390/460 filter set and a dispenser. Usually experiments are carried out in triplicate. During the measurement, a dedicated software program, Thrombinoscope compares the readings from the trigger wells and the calibrater wells, calculates thrombin concentration and displays the thrombin concentration in time. Outcomes from CAT were analyzed in the principal component anaysis (PCA) which is a statistical procedure that allows us to summarize high dimensional data with a smaller number of representative variables that collectively explain most of the variability. Statistical analyses were performed with R 2.5.
Results: Four variables measured from CAT have different sistribution and too large variations. For example, the mean(sd) of each variable (lag time, peak thrombin, time to peak, and velocity index) are 24.66(8.01), 80.16(94.52), 31.28(9.78), 19.08(28.86), respectively. Therefore, to remedy such high variability among variables and to find a score, PCA method is applied. Then the dose values calculated based on the PCA scores have mean 0.393 and a much smaller variation (sd=0.583) (Table 1).

Table 1.

CAT Parameters Range of commercial IVIG products. (show in mean±2SD)

Sample	n	Lag Time(min)	Peak Height(nM)	Time to Peak(min)	VelIndex(nM/min)
A	3	27.70±6.32	25.68±22.04	35.04±6.50	3.53±3.14
B	3	28.07±9.12	24.78±25.12	35.33±10.02	3.51±3.82
C	3	26.30±7.66	35.27±32.92	33.15±8.06	5.22±5.12
D	3	25.07±6.42	40.81±34.90	31.59±6.66	6.31±5.62
E	3	23.82±5.46	33.00±25.68	30.89±5.90	4.72±4.04
F	3	23.45±0.22	44.60±43.34	30.53±1.22	6.48±6.80
G	3	25.86±2.18	26.08±29.90	33.98±4.08	3.37±4.32
H	3	26.22±2.12	27.29±2.16	32.77±2.30	4.20±0.40
I	3	26.11±2.00	25.74±3.30	32.48±1.78	4.07±0.78
J	3	23.45±1.02	47.91±8.00	29.18±0.70	8.39±1.74
K	3	26.44±1.94	24.23±2.38	32.78±1.56	3.84±0.68
L	3	26.11±3.42	24.45±3.38	32.37±3.16	3.91±0.72

The dose levels estimated based on the PCA scores.

Sample	n	dose (mU/mL)
A	3	0.73±0.12
B	3	0.63±0.24
C	3	1.17±0.30
D	3	1.43±0.12
E	3	1.30±0.60
F	3	1.53±0.46
G	3	0.50±0.20
H	3	1.03±0.46
I	3	0.97±0.42
J	3	2.43±0.64
K	3	0.87±0.21
L	3	0.90±0.26

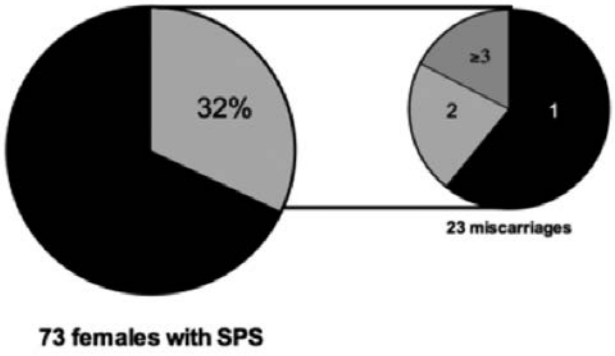
Summary/Conclusions: The PCA value showed a good agreement with four CAT outcomes and less variation. The PCA method could be used to monitor the process of immunoglobulin manufacturing.

PB2219

PRIMARY THROMBOPHILIA IN MÉXICO XII: MISCARRIAGES ARE MORE FREQUENT IN PERSONS WITH THE STICKY PLATELET SYNDROME

G.J. Ruiz Argüelles[1,*], G.J. Ruiz-Delgado[1], Y. Cantero-Fortiz[2], M.A. Mendez-Huerta[3], M. Leon-Gonzalez[4], A.A. Leon-Peña[4], A.K. Nuñez Cortes[4], J.C. Olivares-Gazca[4], J.A. Arizaga Berber[4]
[1]Hematologia, Centro de Hematologia y Medicina Interna, [2]Universidad de las Americas Puebla, [3]Laboratorios Clínicos de Puebla, [4]Centro de Hematologia y Medicina Interna, Puebla, Mexico

Background: The sticky platelet syndrome (SPS) is an inherited condition which leads into arterial and venous thrombosis. There is scant information about the association between the SPS and obstetric complications.
Aims: To assess the relationship of the SPS and fetal loss in a single institution.
Methods: The obstetric history of all the consecutive female patients prospectively studied along a 324 month period, in a single institution with a history of thrombosis and a clinical marker of primary thrombophilia was reviewed.
Results: Between 1989 and 2016, 268 consecutive patients with a clinical marker of primary thrombophilia and a history of arterial or venous thrombosis were studied; of these, 108 were female patients. Within this subset of thrombophilic female persons, 77 (71%) had been pregnant at some moment. Twenty eight of these 77 patients (37%) had had a spontaneous abortion and 24 out of these (86%) were found to have the SPS. On the other hand, in a subset of 73 female patients with the SPS who had been pregnant, 32% had miscarriages. These figures are significantly higher than the prevalence of abortions in the Mexican general population of pregnant women, which is 12-13% (*chi square*=7.47; p=0.0063). Accordingly, the relative risk of having a miscarriage is 2.66 times higher in female patients with the SPS than in the general population (p=0.0014) (Figure 1).



Twenty-three of 73 (32%) female patients with the sticky platelet syndrome (SPS) had an abortion at some time. 14 patients had one abortion, 5 had two and 4 had three or more.

Figure 1.

Summary/Conclusions: In México, female patients with the SPS experience significantly more spontaneous abortions than the general population. Since the treatment of the SPS is simple and effective and could in turn prevent adverse obstetric outcomes, its investigation in women studied because obstetric complications may be useful and deserves further research.

PB2220

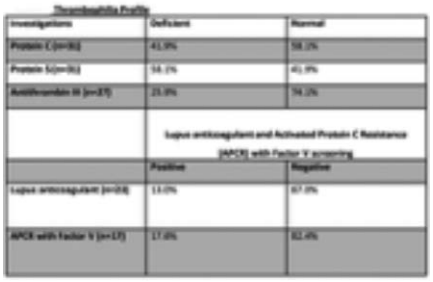
CROSS-SECTIONAL ANALYSIS OF VENOUS THROMBOEMBOLISM IN YOUNG INDIAN MALES; NEW INSIGHTS INTO AN OLD PROBLEM

S.K. Das[1,*], Y. Uday[1], R. Kapoor[1], T. Verma[1], S. Das[1], V. Nair[1]
[1]Hematology, Army Hospital (Research & Referral), New Delhi, India

Background: Venous thromboembolism (VTE) comprising of deep vein thrombosis (DVT) and pulmonary embolism (PE) is one of the major cardiovascular causes of death along with MI and stroke. Though earlier works has suggested that DVT is rarer in Asian population, recent studies have revealed that this might not be so. Most of the studies conducted in Asia in general and India specifically has been on hospitalized patients with minimal representation of young healthy individuals.
Aims: We aimed at studying the disease variables of VTE in young healthy males of Indian origin and compare the same with other Indian studies as well as the global statistics.
Methods: Hospital records of 176 Color Doppler Flow Index (CDFI) and /or Contrast Enhanced Computed Tomography (CECT) proven VTE patients being followed up in a tertiary care hospital was analyzed retrospectively to document cause (provoked/ unprovoked), venous systems involved, thrombophilia profile, duration of anti-coagulation and recurrence.
Results: Among the study population, 49.8% had a provoked VTE. 90.9% subjects had DVT, mostly of the lower limb, 15.3% had PE with DVT, 2.8% had PE alone and 6.2% had splanchninc vein thrombosis including portal vein thrombosis. In the subjects who had undergone thrombophilia profile, 41.9% had Protein C, 58.1% Protein S and 25.9% Antithrombin III deficiency. Lupus anticoagulant screen was positive for 13% of the screened subjects. The average duration of anti-coagulation was 18 months with majority (98.2%) patients on Vitamin K antagonist. The recurrence rate in our study population was found to be 11.4% (Table 1).
Summary/Conclusions: Young Indian males have different disease variables

for VTE as compared to western population. The exact pathophysiology of such differences needs to be studied further to formulate strategies for effective screening and prevention.

Table 1.



PB2221

A PRELIMINARY STUDY ON THE EFFECTS OF AMPHIBIAN CRUDE SKIN SECRETIONS ON SOME PARAMETERS OF HEMOSTATIC SYSTEM

I. Nikolaeva[1,*], O. Marushchak[1], O. Oskyrko[1], T. Halenova [1], O. Savchuk[1]
[1]Biochemistry, Educational and Scientific Centre "Institute of Biology and Medicine", Taras Shevchenko Kyiv National University, Ukraine, Kyiv, Ukraine

Background: A lot of bio-chemical compounds from secretion of the amphibian skin glands with various biological activities have been isolated and characterized. Several recent studies indicate that amphibian skin secretions can be a source of molecules affecting the platelet activity. We are interested to look for other bioactive components of the amphibian skin which exhibit ability to influence on diverse parameters of hemostatic system.
Aims: We performed a preliminary study of the some effects of amphibian crude skin secretions on hemostasis.
Methods: Adult specimens (both sexes) of *Bombina bombina, Bombina variegata, Bufo bufo*, and *Bufotes viridis* were collected from outdoors in Kyiv region of Ukraine. The crude skin secretions were collected by washing with ultrapure water and centrifuged to remove debris. The supernatants were lyophilized and kept at −20 °C till use. In the experiments we used fresh prepared water solution of lyophilized skin secretions. Protein concentration was determined by Bradford method with BSA as a standard. Rabbit platelet-rich plasma (PRP, $2x10^5$ cells/μL) and platelet-poor plasma were obtained following standard protocols. Platelet fraction (PF) was purified by gel-filtration on Sephadex G 50 column. Platelet aggregation was measured by aggregometer AT-02 (Medtech, Russia). Coagulation parameters (prothrombin time (PT), thrombin time (TT), as well as activated partial thromboplastin time (APTT)) were measured by coagulometer (Rayto, RT-2201C) using corresponding commercial kits (Renam, Russia).
Results: The lyophilized *B. bufo* skin secretions in dose-dependent manner induced platelet aggregation in both PRP and purified PF; its final concentration of 50 mg of total protein/mL caused the same effect as $5x10^{-6}$M ADP. These results indicated that skin components acted directly on platelets, maybe through their surface receptors. The lyophilized skin secretions of *B. variegata* and *B. viridis* also activated platelet aggregation but their effects were lower than *B. bufo* skin secretions. The skin secretions from all studied amphibian did not influence on PT and TT except *B. viridis* which prolonged TT by 40%. The values of APTT were significantly enhanced in 3.4 and 2.3 times under the influence of crude skin secretions (final concentration of 0.2 mg total protein/mL plasma) of *B. bombina* and *B. variegata*, respectively.
Summary/Conclusions: The obtained results indicate the prospects of the search for potential modulators of hemostatic system among the amphibian skin bioactive compounds. To establish their physiological and functional mechanisms of action, the further purification and characterization of components from the skin gland secretions are necessary.

PLASMINOGEN-DEFICIENT PATIENTS

H. Kızılocak[1,*], G.N. Özdemir[2], G. Dikme[1], B. Koç[1], G. İskeleli[3], B. Dönmez Demir[4], N.M. Christiansen[5], M. Ziegler[5], H. Özdağ[4], V. Schuster[5], T. Celkan[1]
[1]Istanbul University Cerrahpasa Medical Faculty, Pediatric Hematology-Oncology, [2]Kanuni Sultan Süleyman Education and Research Hospital, Pediatric Hematology Oncology Dept., [3]Istanbul University, Cerrahpasa Medical Faculty, Ophthalmology, Istanbul, [4]Ankara University, Biotechnology Institute, Ankara, Turkey, [5]University of Leipzig, Leipzig, Germany

Background: Congenital plasminogen (Plg) deficiency is a rare autosomal recessive disorder that leads to the development of ligneous membranes on mucosal surfaces.
Aims: Here we report our experience with local and intravenous fresh frozen plasma (FFP).
Methods: Our cohort consisted of 14 patients and their 8 first-degree relatives. The patients have been diagnosed between 3 months and 18 years of age, and the median age at the time of first clinical manifestation was 4.5 months (range 3 days to 12 months).
Results: Conjunctivitis is the main complaint, hydrocephalus and hearing loss follow. In 10 patients, ligneous membranes were surgically removed but all recurred. Nine patients were treated with intravenous and conjunctival FFP. Two patients had no complaints after treatment. Most patients needed transfusion with FFP every three weeks. Only one patient had severe endophthalmitis and lost vision in one eye before treatment. Two female patients and one male patient had undergone multiple surgeries for ligneous conjunctivitis despite being treated with FFP. The response rate to FFP treatment was 6/9 (66%). Another 8-year-old female with severe bronchial membranes was treated with FFP and t-PA through bronchoscopy. Venous thrombosis did not occur in any of the patients. Nine have consanguineous parents. The genetic evaluation of our patients revealed heterogeneous mutations as well as polymorphisms.
Summary/Conclusions: The diagnosis and treatment of Plg deficiency is challenging, and there is no consensus on treatment. Topical and iv FFP may be used with clinical outcome.

PB2223

THE TREATMENT OF HEREDITARY TROMBOPHILIA DURING PREGNANCY

M. Theodosiou[1,*], I. Ionita[1,2], E.-C. Budai[1,2], C. Hategan[1], D.-N. Oros[1,2], E.-C. Fenes[1], R.-S. Buriman[1], H.-M. Ionita[1,2]
[1]Hematology, Spitalul Clinic Municipal de Urgenta Timisoara/Municipal Emergency Hospital TImisoara, [2]Hematology, Victor Babes University of Medicine and Pharmacy Timirosara, Timisoara, Romania

Background: Thrombophilias are genetic conditions that increase the risk of thromboembolic disease. The use of anticoagulant therapy during pregnancy is challenging because of the potential for both fetal and maternal complications. The most common complication is venous thromboembolism.
Aims: This study is conducted in order to assess the importance of treatment during pregnancy for women with hereditary thrombophilia, the risks of not treating the disease or treating incorrectly.
Methods: This study includes a total of 207 women, from which 83% were treated with low molecular weight heparin and Aspirin during pregnancy regardless if it was their first pregnancy or not and the rest 17% remained untreated during pregnancy. The success of the treatment is based on the completion of the pregnancy and the good health of the fetus.
Results: A total of 207 women were included into the study, 172 were treated with low molecular weight heparin and Aspirin while 35 were treated with just Aspirin. Out of 172 patients in the low molecular weight heparin group 155 managed to give birth which accounts for a 90% success rate with a reported case of fetal growth restriction and 2 cases of abruption while the remaining 17 women which represent the 10% of the treated patients were unsuccessful in completing their pregnancy with 14 women presenting pregnancy loss on the first trimester and 2 having late fetal loss, only one case of preeclampsia was recorded. Out of the 35 women who did not receive treatment with low molecular weight heparin and only with Aspirin, 21 managed to complete their pregnancies representing the 60% out of which 2 cases presented with Abruption and 4 cases with fetal growth restriction, out of the 14 women who represent the 40% who were unsuccessful in completing their pregnancies 7 cases were recorded during the first trimester while 3 more had late fetal loss and 4 cases of preeclampsia.
Summary/Conclusions: Women treated for thrombophilia had a lower percentage of fetal loss than their no treatment group counterparts. There is an urgent need for appropriate guidelines for these patients in our medical center.

PB2224

LEARNING ABOUT VALIDATIONS OF THE DVT SCREENING TEST IN PATIENTS WITH SUSPECTED UPPER LIMB THROMBOSIS: A PERSPECTIVE FROM THE CLINICAL PRACTICE

H.N. Fernandez - Leyva[1,*]
[1]Haematology, Croydon University Hospital, London, United Kingdom

Background: Deep vein thrombosis (DVT) of the upper limbs represents 1-4% of DVT, most of them related to central venous catheter and / or malignancy. Thrombosis involving the deep veins (ie, subclavian, axillary, brachial) can lead to complications as pulmonary embolism (PE) and long-term sequelae. PE from upper extremity sources accounts for about 6% of cases. Initial treatment in acute context include fibrinolysis and subsequent anticoagulation (Grade 2C). When symptomatology is mild and/or onset of symptoms undetermined (>2 weeks), minimum anticoagulation 3 months is recommended. If there are associated anatomical abnormalities, the possibility of surgical vascular thoracic decompression must be assessed.

Aims: To ascertain D-dimer diagnostic accuracy for upper extremity DVT.
Methods: A retrospective audit was undertaken to determine the aetiology and clinical presentation on patients which UDVT at presentations. Patients wich a formal malignacy confirmed before the diagnosis was excluded. A D dimer (DD) with a cutt off cut off levels *validated for lower limb* DVT was performed.
Results: A total of 18 patients was identify in the period of 2012 to 2016. All the cases investigations included Doppler US or CT/MRI and in 30% of the patients the thrombosis was confirmed via contrast venography as a reference standard test. The gender predominan was male in this group the symptomatology were related to physical efforts in a 60% (Paget-Shroëtter Syndrome) whereas in female serie the predominant was thrombophilic defects (factor V Leiden). The average age was 33 years (ranging from 21 to 68 years) and 2 elderly patients a new diagnosis of cancer was **c**onfirmed (thyroid and lung) (odds ratio, 3.24; 95% CI, 1.13-9.38). The 85% of the patients had an unprovoked event; four patients have a diagnosis of catheter related thrombosis and four cases a thrombofilic defect (factor V Leiden) precipated by anticonceptive. Two patients had a diagnosis of SLE. We had four cases of positve DD screening (both were marginally elevated, P <0.01) . The risk of re-thrombosis was non significative but in the subanalysis of relapsing thrombotic event populations the risk of relapse increased proportionally in relation of thrombofilic defect and high BMI. A trend towards a higher rate of recurrent thrombosis (was observed among patients with BMI>25 (42.6%) compared to those with a BMI <25 (33%). This difference reached statistical significance in women with BMI>25, who had recurrent event in 51.7% of the cases *vs* those with BMI <25 (29.7%) (p <0.05 CI 0.03, 0.41).
Summary/Conclusions: In the unprovoke serie the relation of DD was positive in less tan 30% of the cases and non stadistically significative (p <0.01). In the case of subclavian vein oclusion this is result in limited clot burden (which explain the correspondence with negative DD value). The risk of re-thrombosis is asociated with thrombophilic defect and high BMI esclusively. The DD adjusted to age and specific young population need to be adressed (age adjusted DD cut off adpated of the specific population). A prospective studies of DD in suspected UDVT need to be adressed.

PB2225

THE INFLUENCE OF HEPARINOID FROM THE PEONY ROOTS ON THE THROMBUS DISSOLUTION

M. Lyapina[1,*], T. Obergan[1]
[1]M.V.Lomonosov Moscow State University, Moscow, Russian Federation

Background: Many plants have an effect on the blood clotting system. It is known that there are heparin-like substances in some types of peony roots (Paeonia lactiflora, Paeonia suffruticosa). It proved that there is an anticoagulant activity in extracts from such roots.
Aims: The intention is to show the inhibitory effect of the extract of Paeonia lactiflora roots (EA) on processes fibrin and thrombus formation.
Methods: We used the standard coagulologic methods for determining anticoagulant activity by APTT test, antiplatelet, total fibrinolytic activity (TFA), fibrindepolymerizing activity (FDPA). Experiments were carried out in accordance with ethical principles and documents recommended by the Declaration of Helsinki of the humane treatment of animals. We used an animal model with prothrombotic condition caused by intravenous administration of subthreshold doses of tissue thromboplastin at a dose of 0.6 -0.7 ml per 200 g body weight in rats. After 30 min after injection of thromboplastin, we injected intraperitoneally 0.1 mL of 1% of extract of EP and after 30 minutes we determined parameters of hemostasis in the blood plasma.
Results: It was shown that after administration of the indicated doses thromboplastin occurs hypercoagulability in blood plasma of animals (APTT decreased by 23% SFA - 15%, FDPA -12%; increased platelet aggregation by 18% compared to control animals not receiving thromboplastin). Normalization of blood clotting is installed in the experimental rats after application EP (recovery of platelet aggregation to 98%, APTT- to 100%, up to 95% SFA- FDPA and - up to 67% compared with control). The high degree of FDPA indicates the ability of EP to obstruct the process of the formation of fibrins and thrombosis. Heparin components in EP interact with fibrin monomers which do not participate in their conversion to fibrin polymer. As a result, stable fibrin polymer or thrombus is not formed.
Summary/Conclusions: Consequently, the extract of Paeonia lactiflora roots containing heparinoid contributes to the restoration of coagulation properties in blood of animals in prothrombotic condition and prevents thrombosis. In the initial stages of fibrin formation, it causes the thrombus dissolution.

PB2226

LOW MOLECULAR WEIGHT HEPARIN AND HIGH MOLECULAR WEIGHT HEPARIN: COMBINATION WITH ADRENORECEPTOR ANTAGONISTS AND PREVENTION OF THROMBUS FORMATION

M. Golubeva[1,*], M. Grigorjeva[1]
[1]Biology, Lomonosov Moscow State University, Moscow, Russian Federation

Background: Rethrombosis and thromboembolia are the most common side effects of thrombolytic therapy. One of the possible causes of thrombosis is the entering of thromboplastin in the blood stream. Marker of thromboplastin is an intrinsic membrane glycoprotein 5'-nucleotidase (5'NT) that is present as an enzyme in a wide variety of cells. Recently it was shown that compensatory reaction of haemostasis system by using different fibrinolytic drugs was connected with the stimulation of the sympathetic nervous system. Besides, it is known that selective and nonselective α–adrenoreceptor blocking agents have fibrinolytic and antiplatelet effects. The prevention of thrombosis complication is very important field of pathophysiology and medical practices. Therefore, we studied effects of different α–adrenoreceptor antagonists and the influence of these substances combinations with various anticoagulant and fibrinolytic agents on blood coagulation during many years.
Aims: The study of the influence of low molecular weight heparin (LMWH, 4.4 kD) and high molecular weight heparin (HMWH) and their combinations with different α –adrenoreceptor antagonists (AA) on experimental thrombosis prevention.
Methods: Experiments were carry out on 50 white laboratory rats weighing 200-230 g according to the ethical principles of the Helsinki Declaration. Anticoagulant and antithrombotic effects of LMWH or HMWH were studied in two rat models of thrombosis – thrombosis in v. jugularis (Wessler) and thrombosis in arterio-venous shunt (direct registration of blood pressure). The α–AA digydroergotoxin (DET – 1mg/kg), α_1–AA prazosin (PZ – 2mg/kg), LMWH or HMWH (40 USP/kg) were injected in v.jugularis. Saline was administrated in control rat groups. The thrombus were formed 15 or 180 min after substances injected. The degree of thrombus formation (TF) was detected in ball (Wessler model) and by time of TF (arterio-venous shunt model). In blood plasma the activity of 5'NT was detected. The results were processed statistically.
Results: The increase of anticoagulant and antithrombotic effects of LMWH or HMWH by pretreatment of DET or PZ were shown in both animal models of venous thrombosis. The degree of TF by Wessler model may be estimated as 3.7 (saline), 1.3 (LMWH), 1.8 (HMWH), 0.9-1.1 (DET+ LMWH or PZ+LMWH) and 1-1.3 (DET+ HMWH or PZ+HMWH). Besides, it has been shown that TF was accompanied with significant hypercoagulation of blood: 5'NT activity was increased in 2 time comparatively with normal level. LMWH or HMWH combinations with DET or PZ administration led to normalization of 5'NT level in blood plasma. In arterio-venous shunt model it has been shown that the time of TF was 2 min (saline), that was accompanied with the decrease of blood pressure (on 40-50 mmHg). In this case the time of TF was prolonged in 4 time (LMWH) or 2 time (HMWH) comparatively with saline group 15 min after injection; in 4.5-5 time (DET+ LMWH or PZ+LMWH) or 3-3.5 time (DET+HMWH or PZ+HMWH) comparatively with saline group 180 min after injection.
Summary/Conclusions: Thus we confirmed that LMWH (as one, as in combination with α–adrenoreceptor antagonists) has definite advantages over HMWH. Besides our results show that α–adrenoreceptor antagonists significantly improvement antithrombotic effect of anticoagulant agents (LMWH and HMWH). Therefore the combination of LMWH with selective and nonselective α–adrenoreceptor antagonists may be effective used for prevention of venous thrombosis development and thromboembolia.

PB2227

THE POLICY AND PRACTICE OF ANTICOAGULATION THERAPY AMONG CLINICIANS IN SOUTHEAST NIGERIA.

T. U. Nwagha[1,*], R. Anakwue[2], O. Ukpabi[3], E. Onwubuya[4], N. Obeka[5], I. Okoye[6], B. Azubuike[6]
[1]Haematology & Immunology, [2]Internal medicine, University Of Nigeria Teaching Hospital, Enugu, [3]Internal medicine, Abia state Teaching Hospital, Umuahia, [4]Internal medicine, Nnamdi Azikiwe Teaching Hospital Nnewi, Awka, [5]Internal medicine, Federal Medical center , Abakiliki, [6]Internal medicine, Amaku Specialist hospital, Awka, Nigeria

Background: In the absence of anticoagulation therapy, the risk of Venous thromboembolism; deep-vein thrombosis (DVT) and pulmonary embolism(PE)in medically ill patients is comparable to that in moderate-risk surgical patients. Previous studies have revealed grossly inadequate knowledge and a dismal practice of anticoagulation among healthcare workers in some resource poor countries. Prophylactic anticoagulation is under-prescribed in Nigeria, South Africa, as well as in many other countries in Africa.
Aims: The aims of the study are to evaluate the practice of anticoagulant therapy. It will also document the frequency of drug-induced complications resulting from the use of anticoagulants and presence of an anticoagulation policy in the hospitals surveyed.
Methods: This is a multicentre cohort survey of the practice of anticoagulant therapy among clinicians in South East Nigeria. A pretested validated questionnaire was administered to clinicians in five tertiary hospitals in the southeast of Nigeria. The questionnaire was designed to assess their practices anticoagulation therapy. The questionnaire was administered consecutively on clinicians in the participating centers. The following institutions participated in the survey: University of Nigeria Teaching Hospital Enugu, Federal Medical Centre, Abakaliki, Federal Medical Centre Umuahia, Abia State Teaching Hospital, Aba and Amaku Specialist hospital Awka. Statistical package for Social Science (SPSS) software, version 18 (SPSS Inc., Chicago, IL) was used for analysis.

Results: A total of 528 clinicians were involved in the survey. There were more males 378 (71.6%) than females, 150 (28.4%) the clinicians who practiced for less than 5years are in the majority 189 (35.8%) and those with 15-20 years of practice 46(8.7%) are in the minority. Only 52 of the respondents (9.8%) claimed their institutions had an anticoagulation policy while 274 (51.9%) of them said there was no such policy and 168 (31.2%) do not know of any policy. Unfractionated heparin was the most frequently used (96.8%) and fondaparinux was the most infrequently used (42%). Most of the prescriptions were done by younger clinicians who are the highest in number. The consultants prescribed heparin and warfarin most, with the newer anticoagulants taking the rear position. Only 193 (36.6%) of the respondents routinely prescribed anticoagulation therapy when indicated. 412(78%) of respondents believe the risk of anticoagulation outweighs the benefits while 439 (83.1%) identified cost is an important variable in prescribing anticoagulation agent. Anti-coagulation prophylaxis was the most frequently used for patients immobilized or bedridden (94.1%); malignancy and atrial fibrillation were the most infrequent reasons for using anticoagulation agents (50.6%) . A total of 63 respondents (11.9%) were not satisfied and 219 (41.5%) were not very satisfied with the laboratory monitoring tool available in their institutions. Bleeding is the most common complication of anticoagulation while the least encountered complications are skin and jaw necrosis among the respondents 492(93.2%), 1(0.2%) respectively.
Summary/Conclusions: This survey has shown the lack of anticoagulation policies among the centers that participated. Our survey has also shown deficiencies in the areas of practice of anticoagulation among the clinicians in the Southeast of Nigeria. These gaps can be remedied by continuous medical education and by the establishment of anticoagulation policies.

Transfusion medicine

PB2228

UMBILICAL CORD BLOOD PLASMA INFUSION PROMOTES BLOOD CELL RECOVERY IN INPATIENTS WITH ACUTE LEUKEMIA UNDERGOING CHEMOTHERAPY

Y. Lu[1,*], X. Zhang[1], X. Li[2], Y. Zou[1], Z. Lin[1]
[1]the third Affiliated Hospital of Sun Yat-Sen University, [2] The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Umbilical cord blood plasma(UCBP) is separated from umbilical cord blood. UCBP contains a variety of hematopoietic growth factors which can stimulate hematopoiesis.
Aims: The aim of this work is to explore the influence of UCBP infusion on blood cell recovery in patients with acute leukemia undergoing chemotherapy.
Methods: Patients with the diagnosis of acute leukemia were included in this study and they were randomly distributed to experimental group and control group. Patients in experimental group received infusion of 100ml UCBP with the same ABO and Rh blood type every day after chemotherapy for five days and patients in control group received placebo for the same time. Blood routine were tested every day until WBC >4.0×10^9/L and PLT >20×10^9/L.
Results: 25 patients were included in the study of which 23 were brought into statistics. 13 patients were in experimental group and 10 in control group. There were no difference in age, gender and dose intensity of chemotherapy between the two groups (P>0.05). The average recovery time of the blood neutriphil granulocyte >0.5×10^9/L in experimental group and control group were respectively (8.53± 3.26) days *versus* (12.92± 4.75) days (P<0.05) and that of PLT >20×10^9/L was respectively (9.24± 3.68) days *versus* (13.15± 5.76) days (P<0.05). No UCBP transfusion-related side effects were found.
Summary/Conclusions: UCBP administration is safe as treatment for cytopenia and could promote blood cell recovery in patients with acute leukemia undergoing chemotherapy.

PB2229

TOWARD BETTER BLOOD TRANSFUSION PRACTICE: A SUCCESSFUL RED BLOOD CELL UTILIZATION TOOLS IN A TERTIARY CARE HOSPITAL

A. Aly[1], G. Mawad[1], E. Alzaabi[1], A. Aly[1,*]
[1]Mafraq Hospital , Abu dhabi, United Arab Emirates

Background: The need for blood in hospitals continues to exceed the volume collected by the transfusion services. The gross over-ordering of blood, in excess of actual and anticipated needs leads to substantial costs and a burden to the transfusion services. In addition, over-ordering leads to non-availability of cross-matched units for other patients who might be in urgent need of transfusion.
Aims: We are aiming to reduce the Cross-match-to-transfusion ratio (C:T ratio) & improve blood utilization in Mafraq Hospital.
Methods: In 2011 the ordering practice at Mafraq Hospital, a designated Trauma Centre, had been evaluated. Data collected retrospectively over a one year period and a C:T ratio adopted by the American Association of Blood Bank was calculated for all various subspecialties including Surgery, Internal Medicine, Pediatrics and Obstetrics and Gynecology. All procedures related to hospital transfusion practice been retrieved and re-evaluated to address gaps. Policy of maximum surgical blood ordering (MSBO) was implemented based upon both results of audits and by discussion and agreement between medical teams. Focused training and education has been followed to increase the awareness of the health care workers. Plus monitoring of C:T ratio on monthly basis, blood bank team had arranged meetings with the departments that were over-ordering cross-matches to explain that group & save test is a safe, effective and financially beneficial strategy. Communicating with the physicians had been the most challenging aspect of implementing the policy changes.Regular audits had been conducted to measure the compliance and effectiveness of the blood management practice.
Results: Compared to the international guidelines, C:T ratios in 2010 was beyond the acceptable target and ranged between 2.5 to 3.2 highlighting the over-ordered cross-matched blood in certain sub-specialties. This practice of ordering was probably because of the fear that blood will not be available, if needed. Following implementation of control and continuous monitoring measures while establishing proper procedures such us transfusion guidelines, administration of blood and blood products and Maximum Surgical Ordering Practice, Mafraq blood bank ,supported by the Transfusion and Tissue & Quality & Patient Safety Committees, achieved a great success in reducing C:T ratio <2 all through 2016 Figure 1. The reduction of C:T ratio had improved blood inventory control and reduced the workload of the blood bank staff. Because fewer units of cross-matched PRBC are being ordered, the blood bank has been able to decrease the number of units of blood stocked in house and hence decreasing the number of expired units &reducing money loss Figure 1. The savings in technologist time is particularly significant since the blood bank is most of the time at a minimal staffing level.

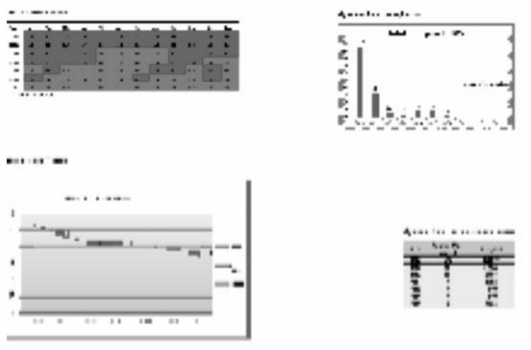

Figure 1.

Summary/Conclusions: There is a tendency to order blood in excess, either by asking for an increased number of units or as a standby precautionary measure. Adherence to MSBO & transfusion guidelines, hospital can achieve C:T ratios below 2.0. The introduction of strategies for improved blood utilization has been shown to be cost effective and safe. Future comparison analysis with facilities with well-established blood management program can enhance the current program and ensure continuous proper utilization.

PB2230

SAFETY AND EFFICACY OF A PROTHROMBIN COMPLEX CONCENTRATE IN VKA REVERSAL AND OFF-LABEL INDICATIONS

M. Marcos Jubilar[1,*], J.A. Garcia Erce[2], N. Martinez Calle[1], J.A. Paramo[1], R. Figueroa[1], S. Villar[1], M. Quintana[3]
[1]Hematology and Hemotherapy, Clínica Universidad de Navarra, [2]Hematology and Hemotherapy, Complejo Hospitalario de Navarra, Pamplona, [3]Intensive Medicine, Hospital Universitario La Paz, Madrid, Spain

Background: Prothrombin complex concentrates (PCC) are highly purified mixtures of plasma coagulation factors that contains vitamin K dependent and anticoagulation factors, they are approved for urgent reversal of vitamin K antagonists (VKA). Massive bleeding-associated coagulopathy guidelines include PCC in their management, although as an off-label indication.
Aims: The aim of the present work is to evaluate safety and efficacy of PCC in a case series of VKA reversal and refractory coagulopathy associated with major bleeding.
Methods: Retrospective review of cases treated with a four-factor PCC between January 2010 to January 2016 in two tertiary Universitary Hospitals. As safety endpoints we evaluated infusion reactions and incidence of thromboembolic events by self reported registry. The efficacy endpoints were studied in two separate cohorts: 1) INR correction for VKA reversal and 2) coagulopathy correction and early mortality (24 hours) in major bleeding coagulopathy.
Results: 328 patients were included (47.25% male), median age 78 years (range 19-102). PCC was used in the following cases: 1) 66.67% in VKA reversal indication (181 patients due to hemorrhage and 33 prior to emergent surgery), mean dose of PCC 1333.51 IU; 2) 30.54% in refractory coagulopathy in major bleeding (30 patients due to massive bleeding protocol activation, 43 patients in hepathopathy coagulopathy and 25 patients in bleeding not related with any of previous reasons) a mean dose of PCC 1681.63 IU was used. Safety endpoint: Two infusion reactions were reported potentially related to PCC use, they were not specified neither as anafilaxia nor as pulmonary edema, and 8 thrombotic episodes were observed (2.4%): 5 pulmonary embolism, 2 deep venous thrombosis and 1 portal thrombosis, 75% of the events appear in the group of VKA reversal. Efficacy endpoint: VKA reversal in bleeding patients was effective in 97% of them, 76.5% with complete reversal of INR value (INR<1,5), 34,25% of patients required red blood cell (RBC) transfusion, with a mean of 1.32 RBC. Prior to invasive procedure VKA reversal was effective in 83% of patients, all procedures taking place with no bleeding complication, 36,3% of patients needed RBC with a mean of 1.12 units. 24 hours mortality in refractory coagulopathy associated to major bleeding was 31,6%, having a worse outcome (40% rate of death) those who suffer a massive bleeding coagulopathy, all death related with absence of bleeding control. A global INR correction happen in 76.7% of patients, complete correction in 40.7%. 63,26% received previous to PCC fresh frozen plasma.
Invasive hemostatic procedures were required in 20% of the whole series.
Summary/Conclusions: A four-factor prothrombin complex was safe and effective as adjuvant treatment in refractory coagulopathy due to major bleeding as well as for the emergent reversal of VKA.

PB2231

TRACEABILITY OF RED BLOOD CELLS IN A HOSPITAL TRANSFUSION LABORATORY

M. Tserga[1], A. Argyrou[1,*], S. Nikolopoulou[1], A. Gafou[1]
[1]Blood Bank, General and Oncology Hospital "Agioi Anargyroi", Athens, Greece

Background: According to European legislation (2002/98/EC, 2005/61/EC) as a requirement of hemovigilance system traceability (confirmation of final destination of blood components in hospitals) information should be kept for 30 years, improving the quality and safety of the transfusion process. Various methods are available from simple paper–based procedures to full electronic blood tracking systems. The ideal goal is to trace the final fate of 100% of the red blood cell (RBC) units, from donor to recipient and vice versa.
Aims: To check the ability to trace each individual unit from donor to recipient or disposal in our hospital.
Methods: To ensure compliance, the minimum traceability data set for retention is a mix of 1) Wards' paper files (file of transfusions and/or patient records: 14/2 wards respectively). 2) HTL electronic records and paper records. The transfusion practitioner is responsible for the collection and maintenance of traceability data.
Results: During the year 2016, the number of RBC units transfused in our hospital was 2128. The traceability status of the transfused units is shown in the Table 1.

Table 1.

Traceability of transfused units			
Traceability	**Description**	**N**	**N total: 2128**
Confirmed	Full match of data	2067/2128 (97.13%)	2067
Presumed	Wrong number of unit in the ward	25/2128 (1.18%)	32
Presumed	No number of the unit in the ward	7/2128 (0.33%)	
Unknown	No data in the ward*	29/2128 (1.36%)	29

* Patients' data has been archived for long- term retension.

Summary/Conclusions: Although we are satisfied that the results represent a reasonably accurate working model of the current situation, the trail of a unit is less reliable after blood has left the HTL. 1. Patients' notes to provide traceability are not totally reliable. It is apparent that the ward staff plays a key- role part in the chain and this highlights the need for them to receive training to emphasize the importance of their contribution to hospital compliance. 2. The indications are that the essential requirements on traceability are not fully met by the current laboratory computer system. A configuration is needed to produce a report which lists components which have been assigned for use but do not have an entry for return to stock or final fate. Ongoing problems will be referred to the Hospital Transfusion Committee. 3. For the longer term ultimately only effective IT system in both wards and HTL can ensure total traceability and we recommend the inclusion of electronic tracking system in the National Blood Donor Registry Programme (EMA)

PB2232

NON-HEMOLYTIC FEBRILE POST-PLATELET-TRANSFUSION REACTIONS IN HEMATOLOGICAL PATIENTS

A. Rakhmani[1,*], E. Mikhaylova[2], I. Dubinkin[3], V. Troitskaya[2], O. Kalmikova[3], M. Danilevskaya[3], T. Gaponova[1]
[1]Clinical Research Department of processing and cryopreservation of blood cells, [2]Clinical Research department of chemotherapy and bone marrow depression, [3]Scientific clinical laboratory quality control and safety of transfusions, Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Platelet concentrate (PC) transfusions are the main method of thrombocytopenia correction in hematological patients, but multiple transfusions could trigger alloimmunity and refractoriness to transfusions.
Aims: Comparison of post-transfusion reactions in hematological patients with individual matching and without individual matching receiving PC transfusion support.
Methods: In 2015-2016, we observed 948 hospitalized patients, who received 12.344 PC transfusions. Individual matching of PCs was performed by cross-matching on the Galileo-Neo (Immucor) analyzer. Statistical processing was performed using the chi-squared test with Yates' correction.
Results: 107 of 948 patients developed refractoriness to PC transfusions (12% of total patients). Out of them, 21 patients received 389 PC transfusions without individual matching. 86 patients received 1705 PC transfusions with individual matching. During transfusions without individual matching to non-refractory patients, 0.003% of non-hemolytic febrile reactions (NHFR) have been record-

ed, after matching to refractory patients the frequency was 0.002%. Before matching to refractory patients, the frequency of NHFR was (0.03%) (Table 1).

Table 1.

Status	Patients	Transfusions	Post-transfusion reactions	% of all transfusions	P
Refractory with matching	86	2027	6	0,002	*P<0,01
Refractory before matching	21	389	15	0,03	
Non-refractory without matching	841	9928	30	0,003	*P<0,01

Summary/Conclusions: The frequency of NHFR in groups with refractoriness with individual matching is significantly lower (10 fold) compared to groups with refractoriness before the matching (P<0,01)*.

PB2233

RARE DONORS AND MALARIA

A. Berzuini[1,*], B. Foglieni[1], M. Spreafico[1], D. Prati[1]
[1]Department of Haematology and Transfusion Medicine, Ospedale A. Manzoni, Lecco, Italy

Background: Migratory flows of sub-saharan (SSA) persons throughout the world are expected to continously increase. A significant proportion of SSA citizens are affected by Sickle Cell Disease (SCD), condition requiring repeated blood transfusions. Many centuries of malaria pressure have induced in SSA natives a homogeneous selection of peculiar haematologic characteristics, such as the absence of high frequency red cell antigens (defining a rare blood) that cannot be found in donors of European descent so that many SCD transfused patients experience the fearful occurrence of red cell alloimmunization. For these reasons haematologists are expecting to access to Rare Blood Banks in order to assure a full match between donor and recipient's blood, that may be obtained from donors sharing the same ethnicity. Unfortunately SSA donor recruitment is counteracted by the widespread diffusion of infections contracted before migration: one of these is malaria. In SSA malaria may occur sublinically and is characterized by a slow antibody clearance. This peculiar condition, the so-called semi-immunity, has been induced by a strong genetic pressure, and is a kind of co-evolutionary process characterized by the co-exhistence and persistence of small entity of *Plasmodium* genome with relative antibodies. Molecular techniques are unreliable to detect a small number of Plasmodia, which may otherwise be sufficient to induce a transfusion transmitted malaria (TTM). The serologic assessment, despite the low specificity, remains the most sensitive and reliable method to detect the semi-immune status in blood donors (1).
Aims: The aim of this study was to assess the prevalence of malaria immunity in a cohort of healthy SSA citizens.
Methods: Since 2010 in our Department of Haematology and Transfusion Medicine we recruited 184 SSA citizens, in good health, who agreed to underwent clinical and laboratory investigations to become a blood donor. All of them were born in SSA Africa and lived there for at least the first 5 years of life. 70% of subjects didn't recognize any previous malaria fever. The last travel/stay in Africa was 1-20 years (median 3 yrs), and 48% of returning people had received prophylaxis. Malaria serology was determined by a commercial enzyme immunoassay kit (Malaria EIA Ab, BioRad).
Results: Overall 75% of persons were positive for malaria antibodies. Serologic positivity was found in 75% of persons no more exposed in 5 recent years and even in 83% (19/23) persons settled in Italy since 10-20 years. Serologic positivity was present in 100% of people from Benin, 85% from Burkina Faso, 78% from Ivory Coast and Cameroon, 63% from Senegal. We followed antibody concentration in 50 persons (136 assays), and we observed a slightly negative trend that, in most cases, was followed by a prolonged phase of low antibody levels. 4/50 became negative after three years.
Summary/Conclusions: The identification of malaria antibodies is essential in SSA native donors and, by far, irrepleaceble in order to avoid the risk of TTM. Until pathogen inactivation techniques will become available, we have a very low expectation to introduce SSA blood in Blood Bank inventories. Haematologists have to wait some years for the forthcoming SSA second generation that will allow to fully match the entire SCD patient community.

EFFICACY AND INFLUENCE OF IRON CHELATION THERAPY ON RED BLOOD CELL TRANSFUSIONS

A. Parvu[1,2,*], M. Iancu[3], A. Vasilache[2], T. Torok[2], I.-A. Zsoldos[1], M. Zdrenghea[1], L. Petrov[2], C. Seles[2], L. Urian[2], A. Todinca[4], C. Truica[5], A. Bojan[1]
[1]Hematology, "Iuliu Hatieganu" University of Medicine and Pharmacy, [2]Hematology, "Prof. dr. Ion Chiricuta" Oncological Institute, [3]IT, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, [4]Hematology, Baia-Mare County Hospital, [5]Hematology, "Iuliu Hatieganu" University of Medicine and Pharmacy, Baia-Mare, Romania

Background: Chelation therapy is recommended for transfused patients that have an elevated serum ferritin level (over 1000 microg/l), evidence of iron overload or received over 20 units of red blood cell transfusions (RBCT). Deferasirox showedefficacy and safety in maintaining or reducing body iron (assessed by liveriron concentration or serum ferritin).Iron chelation therapy was associated with hematopoiesis improvement in transfusion-dependent patients and interruption of Deferasirox treatment of transfusions dependent myelodisplastic patients produced loss of erythroid response.
Aims: Aim of the study: to assess the results of Deferasirox efficacy, side effects and to study if the number of RBCT decreased after starting Deferasirox.
Methods: We have done a retrospective, transversal study including all the adult politransfused patients treated with Deferasirox in three counties Hematology Departments of Nord-West Romanian hospitals. Criteria of Deferasirox treatment: over 20 RBCT, serum ferritine level over 1000 microg/l.
We created a data collection sheet including: demographics, information on patients' disease, serum ferritine level at start of and during treatment, Deferasirox dose, data about dose modification, adverse effects of Deferasirox and their management, reasons for treatment discontinuating, evaluation of commorbidities that could increase serum ferritine level, number of RBCT before and after starting the treatment.
Results: We included 40 politransfused patients treated with Deferasirox, age average 63. The diagnosis included mielodysplastic syndromes (most of patients), thalassemia, other anemias. Myelodysplastic patients were treated with low dose chemotherapy, epigenetic treatment, RBCT and bethatalasemic/anemic patients were transfused. The baseline value of ferritine was between 1075 - 6187 microg/l. Deferasirox dose: 20-30 mg/kg. There was a significant reduction in serum feritine from baseline for all the patients. Ferritine median at start, 3631 microg/l decreases at 1537 microg/l after 6 months of treatment and at 994 microg/l after 12 months of treatment. There were 8 patients that had descendent levels of feritine, but during infectious episodes the ferritine increases for a short period of time. Digestive adverse events appeared in three cases (two cases of diarrhea and one case of digestive hemorrhagic episode). In all these cases the treatment was temporarily discontinued. In three cases, treatment was stopped because low ferritin level (under 500 microg/l). RBCT were administered before (mean 2.43 units/month) and after starting Deferasirox (mean 1.39 units/month), the difference is statistically significant (Student Test, t(39)=6.98, p<0.001). After starting Deferasirox treatment mean number of RBCT decreased, mean of differences (95% CI) was 1.04. We analyzed the group of 23 patients treated with Deferasirox less than 12 months, and the patients treated more than 12 months, 15 patients. In both groups the difference of RBCT means (before and after the start of the treatment) are statistically significant (for the patients treated less than 12 months: Student Test, t(23)=8.12, p<0.001 and for the patient treated more than 12 months: Student test, t(15)=3.03, p=0.008).
Summary/Conclusions: Analyzing our group of 40 patients, Deferasirox proves to be effective and safe. Adverse effects that determined a temporary stop of the treatment were mild/medium short time digestive reactions. The number of red blood cell transfusion significativelly decreased after starting Deferasirox treatment.

LIBERAL *VS* RESTRICTIVE COMPARATIVE TRANSFUSIONAL STUDY IN ONCOLOGICAL POPULATION

M.I. Touzón Andión[1,*], M. Gestal [1], A. Varela[1], M. Castro[1], C. Moinelo[1], R. García de Villaescusa[1]
[1]Transfusion , Centro Oncológico de Galicia, La Coruña, Spain

Background: Allogeneic transfusion therapy is perhaps one of the most widely used treatments without good evidence support, despite many years of application in clinical practice. This, coupled with blood shortages, the impossibility of achieving zero risk, the lack of evidence that transfusion may increase consumption or decrease tissue oxygen debt and the existence of an association with an increase in morbidity and mortality have favoured that we join efforts towards its optimal use.
Aims: Optimal use in our adult oncological population and evidence that restrictive transfusion (TR, Hb 7-9 grs / dl) is not greater or lowerto the liberal transfusion (TL, Hb 8-10 grs / dl), keeping hemoglobin in safe levels for the patient.
Methods: A research was performed from October 1st, 2015 through December 31st, 2016. We analyzed the proportion of patients receiving packed red cells (CH) and the number of units transfused as well as post-transfusion control in order to describe the outcome of the CH *versus* TL strategies in the cancer population under the study.
Results: See Table 1.
Summary/Conclusions: The results obtained in our series of 311 cancer

patients indicate that the restrictive strategy has been equally effective and probably superior to the liberal one maintaining Hb at a safe level in each patient, as well as quality of life and comfort in a subgroup with advanced and terminal cancer.

Table 1.

Transfusional Therapy	Patients (N°)	Hb Pre (X-)	Hb Post (X-)	yield /CH (grs/dl)
RT	192	8,1	9,1	1,0

HIGH RISK OF HBV INFECTION IN VACCINATED POLYTRANSFUSED CHILDREN

M. El-Sayed[1], Z. Said[2], E. A. E. Abou Elmagd[2], E. Salama[3], F. Ebeid[1,*]
[1]Pediatric Department, Ain Shams University, Faculty of Medicine, [2]Microbiology Department, Faculty of Medicine (for girls), Al-Azhar University , [3]Community Medicine Department, National Research Center, Cairo, Egypt

Background: Children receiving chemotherapy for neoplastic diseases are still susceptible to Hepatitis B virus (HBV) infection despite the national HBV vaccination program coverage for all infants since 1992.
Aims: This study aimed to analyze immunity against HBV and occurrence of HBV breakthrough infections in polytransfused children who had been vaccinated during infancy.
Methods: The study included 89 children with hematological disorders and malignancies, who were categorized into group (A): 37 receiving chemotherapy (M:F 20:17; mean age:7.7±4.0) and group (B): 52 polytransfused children (M:F 31:21; mean age:7.6±3.2). A matched healthy control group (n=162) was also included. All patients and controls had received their primary vaccination against HBV in infancy. Quantitative anti-HBs were tested for patients and controls. Patients' sera were tested for HBsAg, anti-HBc, and HBV-DNA (nested PCR for surface, core & x-regions).
Results: Levels of anti-HBs between 10-100 IU/L and ≥100 IU/L were found among 13.5% and 21.6% [group (A)], 44.2% and 11.5% [group (B)] and 32.1% and 10.5% of controls respectively. There was a significant difference in HBsAb between patients receiving chemotherapy (group A) and both groups B patients (p=0.008) and controls (p=0.032). However, no difference was found between polytransfused children [group (B)] and controls.
HBsAg was positive in 21(67.7%) children under chemotherapy [group (A)] compared to 10 (32.2%) polytransfused children [group (B)] (p<0.0005). Overall, 49 patients (55%) were HBV-DNA positive; 44 c-region positive, 7 s-region positive, 2 positive for both c and s-regions and one positive for c and x-regions. Of those, only 21 patients (42.8%) were also positive for HBsAg; while 28 (47.2%) had occult HBV infection (HBsAg-negative). There was no significant difference between patients receiving chemotherapy [group (A)] and polytransfused children [group (B)] (p 0.157), regarding the rate of HBV DNA. Anti-HBs ≥10 IU/L co-existed in 38.7% (12/31) of HBsAg positive patients and 49% (24/49) of HBV-DNA positive patients.
Summary/Conclusions: Children with neoplastic diseases vaccinated during infancy were at a high risk for HBV infection. The effect of immunosuppression on the HBV protective level favored overt HBV infection in children receiving chemotherapy. The co-existence of anti-HBs with HBsAg and/or HBV-DNA demonstrated a possible residual transfusion-transmission risk with mutant HBV strains.

PB2237

THE ISOHEMAGGLUTININ TITERS OF BLOOD BANK DONORS: THE EXPERIENCE OF ISTANBUL FACULTY OF MEDICINE

Z. Karakas[1,*], D. Soydemir[1], M. Yanaşık[1], A. Akcay[2], G. Ozturk[3]
[1]Pediatric Hematology-Oncology, Istanbul University Istanbul Medicine Faculty, [2]Pediatric Hematology-Oncology, Acıbadem University, [3]Pediatric Hematology-Oncology, Acibadem University, Istanbul, Turkey

Background: Isohemaglutinins that develop against ABO blood group antigens are very important in transfusion and transplantation medicine. Today, 30-40% of allogeneic stem cell transplantations are ABO incompatible transplantation, 20-25% of which are major, 20-25% are minor and remaining bi-directionally incompatible transfusion. Our study; based on the knowledge that isohemagglutinins play an important role in blood transfusion policies in patients undergoing ABO incompatible hematopoietic stem cell transplantation(HSCT) has been shaped by the assumption that each healthy blood bank donor may be potential transfusion donors for ABO incompatible HSCT transplant recipients
Aims: In this study, we investigated the isohemagglutinin titer values of the individuals with A, B and O blood groups; the distribution of the isohemagglutinin titers according to the decades and gender. Also we examined the posibility of determining the isohemagglutinin cut off value in Turkish society.
Methods: One thousand five voluntary blood donors (48 female, 957 male), randomly chosen from the donors, providing the criteria to be a standard blood donor in Blood Center Department, Istanbul Faculty of Medicine were studied. This study was approved by the Ethics Committee of Istanbul Medical Faculty. In the donor population group; blood group A (%40) was the most common and blood group AB was the rarest blood group. Accoording to the Rh D phenotypes; 85% of the population was Rh D positive and 15% of the population was Rh D negative.The frequency of our blood group was determined similar with other European countries. The most common age range of one thousand five voluntary blood donors, including the same rate individuals with blood group A, B and O, was the age range between 26 and 35 years. Forward and reverse blood group determination were performed to these donors and also we identified the Anti-B Ig M and Ig G isohemagglutinin titer values for blood group A; Anti-A Ig M and Ig G titer values for blood group B; eventually both Anti-A Ig M /Ig G and Anti-B Ig M/ Ig G izohemaglutinin titer values for blood group O by using column agglutination methods. Statistical analysis was performed with NCSS (Number Cruncher Statistical System) 2007 (Kaysville, Utah, USA).
Results: While the titer value of Anti-A Ig M isohemagglutinin was 1:128 for female individuals with blood group B; the titer values of both Anti-B Ig M (1:128 and 1:256) , Anti-B Ig G (1:1024) and Anti-A Ig M (1:256) isohemagglutinins were statistically significiance in female individuals rather than male ones. The levels of isohemagglutinin in the blood groups A, B and 0 are shown in Table 1A,B. There was no statistical difference in anti-B IgG and IgM titers in blood group A, anti-A IgG and IgM titers in blood group B and anti-A IgG and IgM titers in blood group O between males and females(p>0.05). However Anti-B IgG and IgM antibody titers were higher in females than males in donors with blood group O respectively p=0,017 (p<0,05) and p= 0.001 (p<0,01) (Figure 1 A,B).

Table 1.

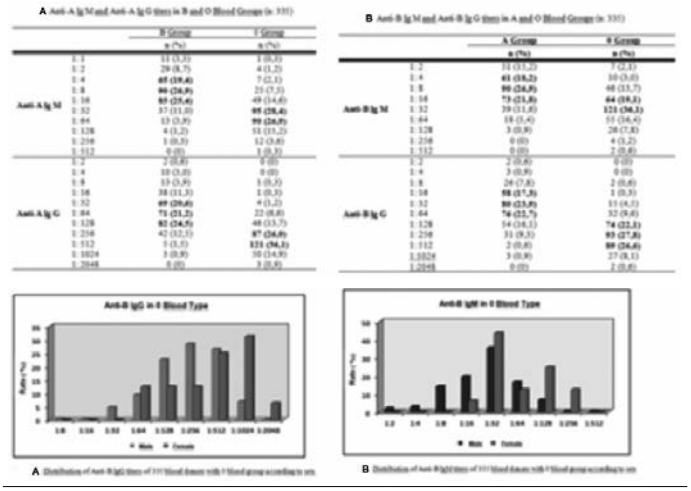

Figure 1.

Summary/Conclusions: Female individuals of blood bank donors participated in our study have higher isohemagglutinin titer values rather then male individuals. Recurrent blood group incompatibility in pregnancy, invasive diagnostic and therapeutical approaches for risk analysis in fetal examination during pregnancy, perinatal complications causing fetomaternal hemorrhage after pregnancy or during birth and lastly autoimmun diseases cause the enchancement of isohemagglutinin titer values in female individuals. Regarding the gender differences; nutrition, vaccination and recurrent blood transfusion history of blood bank donors alsa effect and change the isohemagglutinin titers of individuals. Population spesific isohemagglutinin titer values play a key role in blood donation policy of patients undergoing hematopoietic stem cell transplantation. Consequently; we predict that Turkish community-spesific isohemagglutinin cut off titer values can be identified and we will hope our knowledge on this issue in the future with the increase of research is going to increase further.

PB2238

THE NEW METHOD OF PURIFICATION FACTOR COAGULATION VIII

N. Shurko[1,*], T. Danysh[1], V. Novak[2]
[1]laboratory biochemistry of blood, [2]Hematology, State Institution «Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine», Lviv, Ukraine

Background: The human plasma of blood can be transfused directly to patients or pooled and fractionated into plasma protein products. Plasma contains about 60-80 g/L of protein, of which about 95% are used for many therapeutic prod-

ucts. The main proteins that use for treatment many diseases are albumine (45 g/L), immunoglobulin (8-11 g/L), factors coagulations. The Factor VIII (FVIII) is one of the blood coagulation factor and it deficient causing development of bleeding desorders known as Haemophilia A. The purification of FVIII is generally required for the treatment Haemophilia A or von Willebrand's disease and heavy loss of blood, requires relatively high purity for medical use.
Aims: optimization of a process purification of FVIII by the method of affinity chromatography on the Diasorb-aminopropyl matrix with triazin active dyes as ligands.
Methods: adsorption/precipitation, ion-exchange chromatography on DEAE-Sepharose, affinity chromatography on the Diasorb-aminopropyl matrix with Active Scarlet Damask 4GT as ligands in combination methods of antiviral treatment.
Results: The process plasma fractionation is largest industry segment in manufacture of therapeutic concentrate of plasma proteins. We developed technological scheme that involves fractionation plasma of blood in combinations of classical methods of protein precipitation and two chromatographic steps: ion exchange and affinity chromatography.
Of all plasma fractionation methods, chromatography is the best candidate for purification of factor coagulation, especially FVIII. The methods adsorption/precipitation permits the fractionation of large volumes of plasma, but the quality of the product obtained by chromatography is superior.
We offer: fresh frozen plasma – adsorption of proteins on the barium citrate – adsorption of proteins on $Al(OH)_3$ – adsorption of proteins to PEG-4000 – viral inactivation (solvent-detergent method) – ion exchange chromatography on DEAE-Sepharose – viral inactivation (ammonium thiocyanate) – dye-ligand affinity chromatography (Diasoorb-Active Scarlet Damask 4GT). We got the drug of FVIII with specific activity 69.65±2.24 IU/mg protein.
Summary/Conclusions: we developed technological scheme of plasma fractionation and reached a high degree of purification of coagulation FVIII.

PB2239

PRIMARY TROMBOTIC MICROANGIOPATHIES. REVISION IN A CENTER OF THE LAST 8 YEARS

T. Castaño[1,*], S. Sanchez[1], T. Arquero[1], M. Yuste[1], E. Askari[1], P. Llamas[1]
[1]Fundación Jiménez Díaz, MADRID, Spain

Background: Thrombotic microangiopathies are a group of rare diseases characterized by non-immune microangiopathic hemolytic anemia, thrombocytopenia and involvement of organs of varying intensity, mainly renal and CNS damage. TTP and HUS are the most important forms of TMA and without adequate treatment administered early are associated with high morbidity and mortality.
Aims: To review our experience in the management of the primary TMA and to raise a series of questions that perhaps could improve the approach of these pathologies
Methods: We made a retrospective, descriptive analysis of ten cases diagnosed of primary thrombotic microangiopathy (TTP n=5; typical HUS n=3; atypical HUS n=2) over the last eight years, 70% of which were women with an average age between 40-60 years. Only three cases had previous records of autoinmune diseases (MTCD, RA and HIV), all of which would eventually develop TTP. We requested ADAMTS13 levels on all cases, they were low (<5-10%) only in those pacients diagnosed with TTP, and on the other hand confirming the positivity for Shiga toxin in those patients who eventually developed typical HUS.
Results: Regardless of the diagnosis, 10-12 plasma exchanges were performed to improve the biological parameters of hemolysis, requiring the placement of a central catheter, most commonly at the right jugular vein (70%) due to the lower risk of thrombotic and infectious complications. Although renal involvement is frequent in HUS, only two of the patients required dialysis without recovery of baseline renal function. Is to be noted the part played by the aproval in 2011 of eculizumab and how patients eight years ago suffered a torpid course, requiring a greater number of plasmapheresis and the side effects this carries. However, we still do not know its repercussions out of indication. In our study, it was used in a patient with a diagnosis of HUS associated with an infection with good evolution, although perhaps this result is due only to the natural evolution of the disease. Another controversial point is the use of antibiotics, which are known to worsen the clinical course of these processes, but because of a concomitant infection or new positive determination of the Shiga toxin, as occurred with two of our patients diagnosed of HUS had to be used. Finally, 30% of the patients have relapsed after the first episode with a primary diagnosis of a TTP.
Summary/Conclusions: Thrombotic microangiopathies are a group of processes of enormous complexity, in addition to the low frequency with which they are usually present in our usual clinical practice requiring a large deployment of means to reach an early diagnosis and begin treatment as soon as possible given that the unfortunate prognosis of these patients. With this study we have raised a series of questions to improve the management of this type of diseases:
The need to request levels of ADAMTS13 in patients diagnosed with TTP or to repeat the determination of Shiga toxin in patients with typical HUS as part of the disease follow-up and to try to prevent possible relapses.
The use of eculizumab out of indication in typical HUS and whether the improvement in the picture is due to the drug or by natural evolution of the disease. The real benefit of using plasmapheresis in patients diagnosed with typical HUS. The use of antibiotics and possible harm to the diagnosis made.

PB2240

HAEMOVIGILANCE REPORTS OF ADVERSE BLOOD DONOR REACTION AMONG VOLUNTARY BLOOD DONORS IN TERTIARY CARE HOSPITAL IN KATHMANDU, NEPAL

B. Nepal[1,*]
[1]Blood Bank, Grande International Hospital, Kathmandu, Nepal

Background: Voluntary blood donation is widely considered to be safe with very minimum chance of adverse reaction, which may occur during or after the end of phlebotomy procedure
Aims: To identify and understand the complication of adverse donor reactions though the incidence of reactions of blood donation among blood donor in the tertiary care hospital in Nepal
Methods: This is a prospective study done among voluntary blood donors at Grande International Hospital, Kathmandu, Nepal from February 2013 to March 2015. The outlines of reported and communicated adverse donor reaction were also collected after the blood donation from voluntary blood donors in different locations including outdoor and in-house blood donation drive
Results: In the present study 6,955 whole blood donors were included, during the period of 2 years, 105 (1.50%) adverse donor reactions were reported. Majority 89(84.76%) of adverse donor reactions were mild in nature such as, sweating; 27(25.72%), Light headedness; 19(18.09%), nausea and vomiting; 15(14.28), allergy and bruises;11(10.47%), sore arm; 9(8.58%) and hematoma; 8(7.62%) while 16 (15.24%) were severe adverse reactions similarly, anaphylaxis;11(10.49%), loss of consciousness; 3(2.85%) and convulsive syncope;2(1.90%). Markers of the adverse donor reaction were age, sex, pulse, weight, blood pressure and donation status. Age and first time status were related with significantly higher risk of adverse reaction with 18-23 years old at higher risk compared to 24-55 years old. First time donors were at higher risk compared to repeated volunteer donors
Summary/Conclusions: The results of the study are helpful to identify and understand the complication of adverse donor reactions though the incidence of reactions in the blood donors is lower than in other studies. Donor age and donation status were strong possibilities of complications.

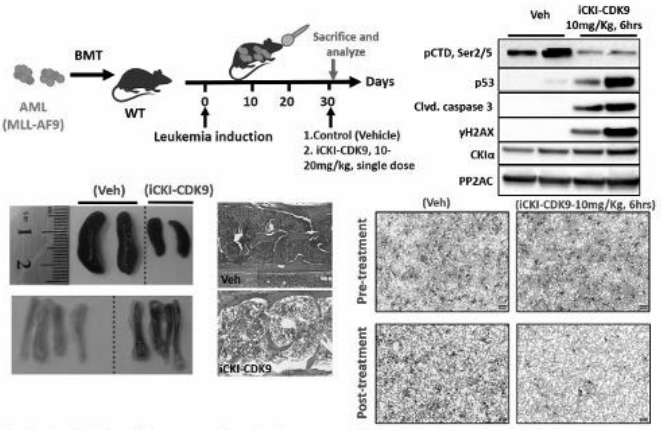
NOVEL SMALL MOLECULE INHIBITORS CO-TARGETING CK1A AND P-TEF-B DISRUPT SUPER-ENHANCERS AND ERADICATE ACUTE MYELOID LEUKEMIA IN A MOUSE MODEL

W. Minzel[1], I. Alkalay[1], A. Fink[1], A. Venkatachalam[1], E. Hung[1], D. Li[2], J. Vacca[2], F. Mercurio[3], M. Oren[4], E. Pikarsky[1], Y. Ben-Neriah[1,*]
[1]Immunology and Cancer Research, Hebrew University of Jerusalem, Jerusalem, Israel, [2]Chemistry, WuXi AppTec, Shanghai, China, [3]BioTheryX Inc, San Diego, United States, [4]Molecular Cell Biology, Weizmann Institute, Rehovot, Israel

Background: Whereas p53 is mostly non-mutated in AML, various oncogenic pathways, frequently through enhancing the activity of its major antagonist Mdm2, suppress its activity. We have previously showed that genetic ablation of CKIα robustly activates p53 *(doi:10.1038/nature09673*). However, with no selective CKIα inhibitors for *in vivo* use, the therapeutic value of CKIα inhibition in hematological malignancies cannot be validated.
Aims: To develop small molecule CKIα inhibitors and assess their effect in mouse models of human leukemia.
Methods: CKIα inhibitors were identified via cell-based screening based on p53 activation. We focused on a small class of pyrazole-pyrimidine scaffolds, which through extensive medicinal chemistry yielded derivatives with high affinity binding, validated by crystallography studies, potent CKIα inhibitory activity and a good pharmacokinetic profile. Anti-leukemic activity was assessed by oral treatment in mouse models of AML: MLL-AF9 and Bcr-Abl Blast Crisis
Results: We first demonstrated the inhibitors' anti-leukemic effect by single oral dose treatment, robustly inducing p53 activation and blast cell cytoreduction (Figure 1).



Single-dose inhibitor effects treated for 6hrs (BM Western blot and blood smear) and 16hrs (tissue records), in heavily leukemic mice, showing strong cytoreduction in the spleen and bone marrow and pro-apoptotic signaling of combined inhibition of P-TEFb (CDK9) and CKIa, evident by RNA Pol II phospho-CTD inhibition and activation of DNA damage response (gH2AX) and p53

Figure 1.

These inhibitors distinguished leukemic from normal hematopoietic stem cells: they did not affect normal hematopoietic CFUs, but eliminated leukemic CFUs at an IC50 <9nM. We tested the long-term oral therapeutic effects of the inhibitors in MLL-AF9 leukemic mice. Whereas all vehicle-treated mice succumbed to the disease within a month, 40-50% of inhibitor-treated mice survived with no signs of disease up to 5 months' observation, nor had the surviving mice any sequela of long-term treatment; all had normal blood counts and normal organ morphology and histology. Long-term leukemia control with possible cure, attesting to eradication of LSCs and preservation of normal HPSCs was demonstrated by transplanting leukemia-treated BM into lethally irradiated mice: all transplanted mice recovered and none showed any evidence of residual disease within 6 months. To elucidate the mechanisms by which the inhibitors distinguished leukemia from normal hematopoietic cells, we profiled the kinome affinity of the inhibitors and further studied their signaling effects *in vitro* and *in vivo*. We found that CKIα inhibitors having potent anti-leukemia activity are distinguished from less active analogues by their capacity to co-target CDK9 and suppress the RNA Pol II elongation factor P-TEFb (CDK9-CyclinT1 complex). This property, validated by co-crystallography studies, enables the inhibitors to disrupt super-enhancers (SE), demonstrated by suppression of chromatin H3K27 acetylation and Brd4 association. As a result, transcription of SE-dependent major anti-apoptotic leukemia oncogenes including Mdm2, Bcl-2 and Mcl-1 was nearly abolished and inhibitor-treated leukemia cells underwent apoptosis. Strikingly, brief drug exposure (10mins *in vitro*; 2hrs *in vivo*) results in prolonged (24hrs) SE suppression. This unique property, which is at variance with the current occupancy-driven pharmacological paradigm, likely, contributes to the dramatic therapeutic effect of co-targeting CKIα and P-TEFb in leukemia.
Summary/Conclusions: We developed a new class of small molecule inhibitors that co-target CKIα and P-TEFb. These inhibitors induce very rapid, robust activation of p53 in synergy with shutdown of leukemic super-enhancers, resulting in a lasting, powerful and specific anti-leukemic therapeutic effects in-vivo, with cure potential.

Background: Mantle cell lymphomas (MCL) are characterized by the primary translocation t(11;14)(q13;q32) involving *CCND1* and IGH genes in virtually all cases. Recently, a small subset of cyclin D1-negative (cyclin D1$^-$) MCL has been recognized. About half of these cases have *CCND2* gene rearrangements and overexpression of this gene. However, the primary oncogenic events in cyclin D1$^-$/cyclin D2$^-$MCL still remain elusive.
Aims: To identify potential mechanisms driving the pathogenesis of cyclin D1$^-$/cyclin D2$^-$MCL.
Methods: We investigated 66 cyclin D1$^-$/SOX11$^+$MCL cases by a combination of fluorescence *in situ* hybridization (FISH), gene expression profiling by Affymetrix U133+2.0 and qPCR (n=51), and copy number arrays (n=47) (Agilent CGH 1M, Affymetrix Oncoscan and 500K). Six cases were investigated by genome-wide sequencing including 4 mate-pair whole-genomes, 4 whole exomes, and 1 whole-genome sequencing. The male/female ratio was 2.5:1 and median age at diagnosis 66 years.
Results: Most cyclin D1$^-$MCL (49/51, 96%) showed overexpression of other G1 cyclins: *CCND2* in 33/50 (66%), *CCND3* in 12/51 (24%), and moderate overexpression of both *CCNE1* and *CCNE2* in 4/35 (11%). *CCND2* rearrangements were detected by FISH in 25/33 cases (76%) with *CCND2* overexpression, but the remaining *CCND2*$^+$ cases and those with *CCND3* overexpression did not show *CCND2*, *CCND3* and IG rearrangements using currently used break-apart probes. Interestingly, by mate-pair whole-genome and whole-exome sequencing analyses we discovered cryptic insertions of IG light chain regions including the enhancer regulatory elements (2 IGK and 1 IGL) near *CCND3* gene in the three cases with cyclin D3 overexpression. These rearrangements were confirmed by Sanger sequencing and FISH with specifically designed probes to recognize the cryptically rearranged regions. Furthermore, using these probes we detected 6 additional cases with cryptic IGK-*CCND3,* as well as 3 cases with IGK-*CCND2* juxtaposition in tumors with high levels of *CCND3* and *CCND2,* respectively. Taken together, 74% and 18% cases corresponded to cyclin D2$^+$ and cyclin D3$^+$ MCL, respectively, whereas 6% showed overexpression of *CCNE1* and *CCNE2* without gene rearrangements. The whole-genome analysis of one cyclin D1$^-$ MCL with *CCNE1* and *CCNE2* overexpression identified 29 somatic protein-coding mutations, 42 complex structural variants and 24 copy number alterations (including *CDKN2A* and *RB1* homozygous deletions) but not rearrangements involving any of the IG genes or G1 cyclins. The global genomic profile of 47 cyclin D1$^-$ MCL was highly complex (mean 13 alterations/case) and similar to 102 conventional SOX11$^+$ MCL, with significantly more gains at 7p and 18q in the cyclin D1$^-$ MCL. Moreover, 32% cases had chromothripsis at least in one chromosome.
Summary/Conclusions: We have identified a novel IG light chain locus-associated rearrangement, consisting of cryptic insertion of IG enhancer near *CCND3* gene that leads to cyclin D3 overexpression. Similarly, we found cryptic insertions of IGK enhancer region into *CCND2* gene. Both aberrations were undetectable by cytogenetics and FISH break-apart approaches. Overall, 65/66 (98%) MCL had G1 cyclin overexpression. The detection of these rearrangements with cus-

tom FISH probes or that of high levels of *CCND2* or *CCND3* by qPCR, together with SOX11 expression, are helpful diagnostic tools to recognize cyclin D1− MCL and provide insights on the pathogenesis of this rare subgroup.

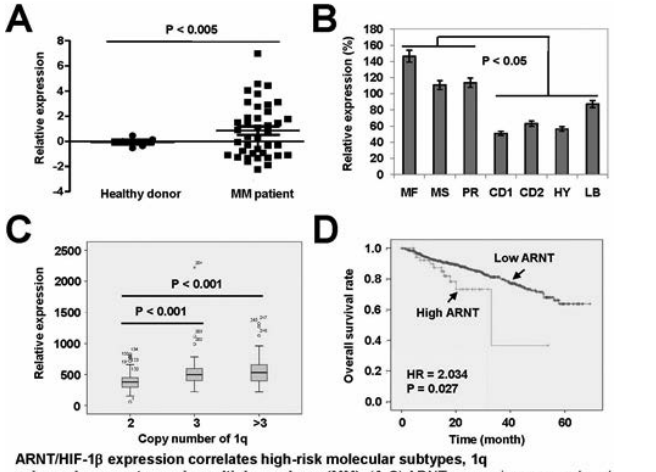
ARNT/HIF-1BETA LINKS POOR CLINICAL OUTCOME TO MICROENVIRONMENTAL HYPOXIA AND HIGH-RISK 1Q GAIN IN MULTIPLE MYELOMA

F. Jin[1,*], X. Liu[1], C. Wu[1], P. Yang[1], X. Yu[1], X. Wang[2], L. Ye[3], Y. Sun[4], J. Sun[1], S. Gao[1], Y. Dai[4]
[1]Department of Hematology, [2]Department of Neurology, [3]Department of Spine Surgery, [4]Laboratory of Cancer Precision Medicine, The First Hospital of Jilin University, Changchun, China

Background: 1q (1q21 gain) is a common high-risk subtype of multiple myeloma (MM), which drives MM progression, confers drug resistance, and correlates with inferior outcome. However, the molecular mechanism underlying the adverse prognostic roles of 1q remains largely unclear. Recently, 1q has been linked to hypoxia and resulting drug-resistant gene expression.
Aims: To understand the function and clinical significance of hypoxia-induced factor-1β (HIF-1β), a gene located in the 1q21 region, in 1q MM and hypoxic microenvironment.
Methods: The relationship between 1q or HIF-1β and Btz response or overall survival (OS) was analyzed in patients with newly-diagnosed MM (NDMM). Western blot and qPCR analyses were performed to determine expression of HIF-1β and other 1q21 genes in 1q+ *vs* 1q− or drug-resistant MM cells, or under hypoxia. The function of HIF-1β was evaluated using genetic means and pharmacological inhibitors.
Results: In a cohort of 180 NDMM patients, median OS (mOS) was 29 and 43 months for cases with (w) or without (w/o) 1q (P=0.038), among which 24.3, 43.3, and 43.8 months for 1q copy number >3,=3, and=2 (P=0.030), respectively; whereas Btz-based therapy displayed a marked increase in response rate ≥VGPR, it failed to improve mOS of 1q patients significantly (28.5 and 33.9 months for patients w or w/o Btz treatment, P=0.983); in contrast, Btz treatment dramatically prolonged mOS in patients w/o *vs* w 1q (53.7 and 28.5 months, P=0.016). To explore the molecular basis for the adverse effect of 1q on prognosis, expression of the 1q21 genes related to drug resistance was examined. Notably, robust expression of HIF-1β at protein level was found in 1q+ MM cells, while no difference observed in CKS1B, a biomarker widely used for 1q MM, or PSMB4 and MCL-1. Further, analysis of additional 40 NDMM patients revealed that HIF-1β mRNA level was significantly higher in MM patients, compared to normal donors (n=5, P <0.005); analysis of the microarray database UAMS "Multiple Myeloma DataBase" (University of Arkansas) also showed that HIF-1β expression was higher with MM progression, in high (*e.g.*, MF, MS, PR) *vs* low risk (*e.g.*, CD1, CD2, HY, LB; P <0.05) subtypes, or in w 1q *vs* w/o 1q (P <0.001 for copy number ≥3), as well as correlated to shorter OS (P=0.027). In the *in vitro* study, HIF-1β was markedly upregulated in MM cells acquired drug-resistance against Btz and lenalidomide, while no changes observed in other 1q21 genes (*e.g.*, PSMD4, CKS1B). Ectopic expression of HIF-1β in 1q− cells reduced sensitivity of Btz. Hypoxia (1% O_2) or its chemical mimetic lactic acid induced HIF-1β expression and Btz resistance, an event reversed by shRNA knockdown of HIF-1β. Furthermore, hypoxia-induced HIF-1β expression was associated with activation of NF-κB, which was prevented by the IKK inhibitor parthenolide, leading to restoration of Btz sensitivity in Btz-resistant cells (Figure 1).



ARNT/HIF-1β expression correlates high-risk molecular subtypes, 1q gain, and poor outcome in multiple myeloma (MM). (**A-C**) ARNT expression was analyzed in newly-diagnosed MM patients vs normal donors (**A**), in high- (MF, MS, PR) vs low-risk (CD1, CD2, HY, LB) molecular subtypes of MM patients (**B**); and in patients with (copy number = or > 3) vs without 1q (copy number = 2) MM. (**D**) The relationship between ARNT expression and overall survival of MM patients was examined by Kaplan-Meier analysis.

Figure 1.

Summary/Conclusions: Together, these findings argue that HIF-1β represents a novel biomarker for risk stratification and prognostic prediction of MM patients, especially those with high-risk cytogenetics such as 1q. They also suggest that HIF-1β might play a critical role in drug resistance related to microenvironmental factors (particularly hypoxia) and 1q21 gain, therefore serving as a potential therapeutic target for development of agents or therapy to overcome intrinsic and acquired drug resistance in MM.

ANTI-CD69 MAB TREATMENT INCREASES THE CAPACITY OF NK CELLS TO ELIMINATE HYPER-REACTIVE ALLOGENIC T CELLS AND PREVENTS ACUTE GRAFT *VERSUS* HOST DISEASE

K. Tsilingiri[1,*], M. Relano[1], Antonio Balas[2], Valle Gómez García de Soria[2], Yaiza Pérez García[2], C. Muñoz-Calleja[2], P. Martin[1]
[1]Centro Nacional de Investigaciones Cardiovasculares, [2]Hospital Universitario de la Princesa, Madrid, Spain

Background: Hematopoietic stem cell transplantation remains the best therapeutic option for blood malignancies. Acute graft *versus* host disease (aGvHD) is one of the main potentially fatal complications of this treatment with an incidence as high as 50%. The NK cell population has been extensively studied as a potential target for treatments, as these cells have the capacity to potentiate the graft *versus* leukemia effect with a minimum risk for graft *versus* host reactions. Indeed, the abundance of circulating NK cells has been inversely correlated with the probability to develop (aGvHD). CD69 is a C-type lectin expressed on the surface of certain immune cell progenitors as well as activated mature leukocytes. CD69$^{-/-}$ NK cells were previously shown to eliminate tumour cells more effectively than WT NK cells.
Aims: We wished to examine whether CD69$^{-/-}$ NK cells would have a higher cytolytic capacity against activated allogenic T cells and whether this would lead to successful aGVHD prevention.
Methods: We took advantage of a fully allogenic aGvHD mouse model in which wild type (WT) or CD69$^{-/-}$ BALBc mice were lethally irradiated and reconstituted with C57/BL6 HSCs and naïve T cells. Results were confirmed by *in vivo* killing assays as well as by use of CD69 neutralizing antibodies. Mouse strains deficient in T cells, B cells and NK cells were used to establish the NK cells as the population responsible for the observed phenotype. Mass cytometry was employed for extensive phenotyping of WT and CD69$^{-/-}$ NK cells and RNAseq analyses were used to elucidate the molecular mechanisms implicated.
Results: CD69$^{-/-}$mice were highly resistant to aGvHD and significantly more efficient at eliminating hyper-reactive allogenic T cells *in vivo*. This phenotype was reproduced in WT mice treated with a CD69 neutralizing monoclonal antibody during disease induction. Mass cytometry analyses showed that NK cells lacking CD69 expression upregulate the Ly49D and Ly49G2 receptors, responsible for self/non-self discrimination. Further, expression of inhibitory receptors such as CD94/NKG2A was downregulated in CD69$^{-/-}$ NK cells. Finally, *in vivo* data and RNAseq analyses indicated that CD69$^{-/-}$ NK cells are resistant to apoptosis. Preliminary data on NK cell chimerism from HSCT patients indicate that host NK cells can persist shortly after conditiong and transplant, and could be targeted with anti-CD69 mAb to avoid clonal expansion of highly reactive donor T cells.
Summary/Conclusions: NK cells treated with anti-CD69 mAb show a higher capacity to eliminate hyper-reactive allogenic T cells and confer resistance to aGvHD. This data could pave the way for novel therapeutic strategies to optimize allogenic HSCT.

Background: CTL019 is an investigational chimeric antigen receptor (CAR) T-cell therapy with a high rate of durable complete responses (CRs) and a manageable safety profile in a previously reported single-center trial in adult patients (pts) with R/R DLBCL.
Aims: Results of a planned interim analysis of a single-arm, open-label, multicenter, global phase 2 trial of CTL019 in pts ≥18 y with R/R DLBCL (JULIET; NCT02445248) are reported.
Methods: Industry-manufactured CAR T cells were provided to pts at 27 centers on 4 continents using a global supply chain. Pts had received ≥2 lines of chemotherapy and had disease progression after or were ineligible for autologous stem cell transplant (autoSCT). Autologous T cells were transduced with a lentiviral vector encoding an anti-CD19 CAR, expanded, cryopreserved, shipped, and infused at study sites. The primary endpoint (centrally reviewed by an independent review committee) was best overall response rate (ORR: CR + partial response [PR]).
Results: 141 pts were enrolled. Following restaging, bridging therapy, and lymphodepleting chemotherapy (fludarabine 25 mg/m^2/cyclophosphamide 250 mg/m^2/day × 3 days or bendamustine 90 mg/m^2/day × 2 days), 85 pts received a single dose of CTL019 transduced cells (median, 3.1 × 10^8 [range, 0.1-6.0 × 10^8] cells). Median time from infusion to data cutoff (20 December 2016) was 3.7 mo. Median age was 56 y (range, 24-75) and median prior lines of antineoplastic therapy, 3 (range, 2-7). 51% of pts had prior autoSCT. Among 51 pts with ≥3 mo follow-up or earlier discontinuation, best ORR was 59% (95% CI, 44% to 72%) with 43% CR and 16% PR; the primary endpoint was met. CR and PR rates at 3 mo were 37% and 8%, respectively. All pts in CR at 3 mo remained in CR at data cutoff. Efficacy was observed across prognostic subgroups. Median duration of response was not reached. CTL019 was detectable in peripheral blood by quantitative PCR for up to 355 days in responders. Cytokine release syndrome (CRS) was graded using the Penn scale and managed by a protocol-specific algorithm. CRS occurred in 57% of infused pts (17% grade 3; 9% grade 4); no CRS-associated deaths occurred. 16% of pts received tocilizumab for CRS management. 13% of pts had grade 3/4 neurologic adverse events (AEs), managed with supportive care; no cerebral edema was reported. Grade 3/4 cytopenias lasting >28 days and grade 3/4 febrile neutropenia occurred in 21% and 14% of pts, respectively. 3 pts died from disease progression within 30 days of infusion. No deaths were attributed to CTL019.
Summary/Conclusions: This planned interim analysis of a global study of CTL019 in adults with R/R DLBCL confirms the high response rates and durable CRs observed in the previous single-center experience in a cohort of highly pretreated patients. Centralized manufacturing was feasible. CTL019 was generally tolerated without instance of treatment-related mortality. CRS and other AEs could be effectively and reproducibly managed by appropriately trained investigators.

Background: Hematopoietic stem cells (HSCs) are multipotent stem cells capable of sustaining all mature blood cells throughout life. During development, HSCs arise directly from specialized endothelial cells called hemogenic endothelial (HE) cells within the developing aorta-gonad-mesonephros (AGM) region, in a process termed endothelial-to-hematopoietic transition (EHT). However, despite extensive studies in various animal models, the genetic program driving human HSC emergence remains largely unknown.We have previously reported the generation of hemogenic precursor cells from mouse fibroblasts with the expression of the transcription factors (TFs) Gata2, cFos, Gfi1b and Etv6. These TFs induce a dynamic, multi-stage hemogenic process that progresses through an endothelial-like intermediate, recapitulating developmental hematopoiesis *in vitro*.
Aims: Here, to better understand the molecular events underlying human HE cell specification we expressed hemogenic TFs in human fibroblasts and mapped the TF binding sites at initial stages of reprogramming.
Methods: To determine the transcription factors binding sites we used Chromatin Immunoprecipitation coupled with sequencing (ChIP-seq).
Results: We demonstrate that human fibroblasts can be reprogrammed into hemogenic cells by the expression of GATA2, GFI1B and FOS. Induced cells express CD34 and CD49f and display dynamic endothelial to hematopoietic transcription programs. In addition, reprogrammed fibroblasts repopulate immunodeficient NSG mice and generate hematopoietic progeny of multiple lineages, including T-cells and myeloid cells. Mechanistically, GATA2 display dominant and independent targeting activity during the early phases of reprogramming while GFI1B depends on GATA2 to bind most of its targets. Interestingly, GATA2 and GFI1B interact and co-occupy a cohort of target sites engaging sites preferentially with AP-1 motifs, including the RUNX1 locus. This cooperative binding is reflected by the engagement of open enhancers and promoters marked by H3K4me3, H3K4me1 and H3K27ac in the fibroblast genome that initiates the silencing of fibroblast genes while activating the hemogenic program.
Summary/Conclusions: Together, these findings uncover a collaborative TF interaction that specify a human hemogenic program and EHT. These findings shed light on the processes controlling human HSC specification and provide means to generate human reprogrammed HSCs at high efficiency for transplantation.

LB2606

BONE MARROW SITES DIFFERENTLY IMPRINT DORMANCY AND CHEMORESISTANCE TO T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

F. Pflumio[1,*], J. Calvo[1], X. Cahu[1], S. Poglio[1], M.-L. Arcangeli[1], T. Leblanc[1], P. Ballerini[2], A. Baruchel[3], J. Landman-Parker[2], E. Delabesse[4], B. Uzan[1]
[1]INSERM, Fontenay-aux-roses, [2]AP-HP Hôpital Trousseau, [3]AP-HP Hôpital R Debré, Paris, [4]CHU Toulouse, Toulouse, France

Background: T-cell acute lymphoblastic leukemia (T-ALL) is a disease of T-cell progenitors, which mainly affects children and young adults. Numerous genomic alterations such as *NOTCH1/FBXW7* mutations, *TLX1/3* overexpression or *SIL-TAL1* deletion are known to induce survival, proliferation and differentiation block in T-ALL cells. Interactions between leukemic cells and their microenvironment also contribute to T-ALL pathogenesis. Cell-cell contacts - Delta-Like/Jagged-Notch1, integrin LFA1/ICAM1 - and secreted factors - such as interleukin 7 and 18 or CXCL12 - are key players in T-ALL development. In the course of the disease, T-ALL cells settle in various environments such as thymus, blood, bone marrow (BM), pleura or lymph nodes, which differ in terms of cell content, extracellular matrix and secreted factors. To which extent these distinct niches imprint niche-specific features on T-ALL cells is not well understood.
Aims: Compare the growth of leukemic cells from human and mouse T-ALL in various BM sites. Uncover novel mechanisms of chemoresistance, in relation with the BM microenvironment.
Methods: We used grafts of human and mouse T-ALL in immune-deficient and normal mice, respectively. We explored the behavior of leukemic cells ex-vivo and *in vivo* after they had engrafted different BM sites of the mouse body (femurs, Thorax and Tail vertebraes). We tested their respective chemoresistance to conventional drugs (dexamethasone, vincristine, cytarabine).
Results: We observed that mouse and human T-ALL develop slowly in tail vertebrae BM compared to thorax vertebrae and femur BM. T-ALL recovered from tail BM display lower cell surface marker expression and decreased metabolism and cell cycle progression, demonstrating a dormancy phenotype. Functionally tail-derived T-ALL exhibit a deficient short-term *ex vivo* growth and a delayed *in vivo* propagation. These features are non-cell autonomous as T-ALL from tail and thorax share identical genomic abnormalities and functional disparities disappear *in vivo* and in prolonged *in vitro* assays. Importantly tail-derived T-ALL display higher intrinsic resistance to cell cycle-related drugs, *i.e.* vincristine sulfate and cytarabine, but not to dexamethasone. T-ALL recovered from gonadal adipose tissues or from co-cultures with adipocytes share metabolic, cell cycle and phenotypic or chemoresistance features with Tail-derived T-ALL.
Summary/Conclusions: These results demonstrate that BM sites differentially orchestrate T-ALL propagation. T-ALL derived from adipocyte–rich BM are associated with quiescence and decreased response to cell cycle dependent chemotherapy indicating that adipocyte-rich aged BM or pathologies enhancing BM adipocyte content may help leukemia escaping drug treatment.
